This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

Electrical

SUPPLEMENT TO "THE ELECTRICAL ENGINEER," JUNE 26, 1891.

THE

ELECTRICAL ENGINEER.

A WEEKLY JOURNAL OF ELECTRICAL ENGINEERING,

WITH WHICH IS INCORPORATED

"ELECTRIC LIGHT."

NEW YORK
PUBLIC
LIBRARY

VOLUME VII. (NEW SERIES.)

FROM JANUARY 2, 1891, TO JUNE 26, 1891.

Electrical.
VGA
++

LONDON:
Printed and Published for the Proprietors by BIGGS & Co., at "THE ELECTRICAL ENGINEER" Offices, 139-140, Salisbury-court,
Fleet-street, E.C.

1891.

SUPPLEMENT TO "THE ELECTRICAL ENGINEER," JUNE 26, 1891.

INDEX TO VOL. VII. (New Series.)

THE NEW YORK PUBLIC LIBRARY
690007
ASTOR, LENOX AND TILDEN FOUNDATIONS
R 1914 L

NOTE.—General Articles, Correspondence, and Companies' Meetings are indicated by heavier type (thus, 290) than the Notes, references to which are shown by light type (thus, 290).

A.

Abel, Sir F., Honours for, 129
Aberystwith University College, 284
Accident, Peculiar, 307
Acme Company's Switches, **317**
Acme Electric Works, New Showroom, 1, 249
Advertisements, Electrical, 26, 50
Aerial Navigation, Trouve and, 226
Africa, Telegraph Extension in, 81
African Cables, 249
African Lighthouses, 2
Agricultural Hall, Exhibition at, 429
Agriculture, Electricity and, 155
Air Ship, An Electric, 201, 306
Allen, W. H., Auxiliary Marine Engines, **96**
Allgemeine Electricitats Gesellschaft, **88**
Almanach Annuaire de l'Electricite, 449
Alternate-Current Condensers, J. Swinburne, **22**
Alternate-Current Distribution, Gutmann, **267**
Alternate-Current Distribution, Stanley and Kelly, **620**
Alternate-Current Distribution, Three-Wire, **290**
Alternate-Current Flow, Effects of, **464**, **486**, **508**, **533**, **558**, **584**
Alternate-Current Influence Machine, **444**
Alternate-Current Motors (*see* MOTORS)
Alternate-Current and Potential Difference Analogies, **628**
Alternate Currents, Shocks from High Pressure, **443**; Erratum, 449, **626**

Alternate-Current Transmission:
  Kapp on, **237**
  at Oerlikon, **237**
  Rotary-Phase System, 308, 377, **413**
  Rotary-Phase System, Dolivo-Dobrowolsky, **335**, **368**, 377, 401, **407**, **430**, **483**

Alternating Currents, Interference with, Ayrton and Sumpner, **277**
Alternating Currents, by N. Tesla, **549**, **555**
Alternators, built like Transformers, **13**
Aluminium, Electrical Production of, 250, 449, 471
Aluminium for Motors, 353
Aluminium, New Name for, 567
Aluminium Shades, 591
America and Bradford, Cable Communication between, 179
America, Electrical Engineers Busy, 353
America, Electrical Engineering, Practice in, 29
America, Electrical Storms in, 568
America, Snowstorm in, 109, **118**
American Statistics, **578**
America, Telephoning to, 331
Andrews, J. D. F., Concentric Wiring, **317**
Anglo-American and French Telegraph Company's Dispute, **468**
Anglo-American Telegraph Company, Meetings, etc., **103**, **128**, **400**
Anglo-German Cables, **123**, 227
Anglo-Portuguese Telephone Company, Meetings, **612**
Appleton, Burbey, and Co.'s Calendar, 25; Catalogue, 50; Work of the Year, **65**
Appointments Filled, 25, **48**, 49, 129, 153, **187**, 203, 329, 425, 449
Appointments Vacant, 25
Arc Carbons, Saunderson's, 281, **626**
Arc Lamp, Contades, 401
Arc Lamp-posts for the City, 618
Arc Lamps, Candle-power of, 281
Arc Lamps, Continuous, 499
Arc Lamp with Rotating Carbons, 353
Arc Lighting, E. Thomson, **319**, **334**
Arnot, A. J., in Australia, 520

Arts, Society of:
  Cantor Lectures on the Electromagnet, S. P. Thompson, **17**
  Cantor Lectures on Power Transmission, G. Kapp, 154, **190**, **208**, **237**, **239**, **265**
  Conversazione, 591
  Electricity and the Body, Lawrence and Harries, **325**, **349**
  Funds of, 615
  Medal Awarded by, 615

Asbestos, Italian, 331
Atkinson, L. B. and C. W., Electric Mining Machinery, **137**
Atkinson's Feed-Water Heater, **230**
Atlantic Cable, First, Reminiscences of, **572**
Australian Cable Rates Reduction, 177, 353, **424**
Ayrton and Perry's New Meters, **346**
Ayrton, Prof., Lectures by, at City and Guilds Institute, 25, 449
Ayrton and Sumpner, Alternate-Current and Potential Difference Analogies, **628**
Ayrton and Sumpner, Interference with Alternating Currents, **277**
Ayrton and Taylor, Tests of a Transformer, **276**

B.

Balancing Engines, 225
Balloon, Electric, 201, 306
Barker's Stores, Motors at, 1
Barnett, Wynne, and Barnard, 250, **604**
Barrell, F. R., Acceleration due to Gravity, **126**
Bath Chair, Vaughan-Sherrin's Electric, 106

Batteries, Primary:
  Dalle, Molle, and Co.'s Dry Cell, 249
  Effect of Atmospheric Pressure on, 471
  Hellesen's Dry Cell, **148**
  Maquay's, 404
  Meresole's Dry Cell, 178
  Osborn and Co.'s, 472
  Perreur-Lloyd's, 451
  Pollak and Meritens, 449
  Secret Solutions, S. T. Mackie, **19**
  a Simple, **553**
Batteries, Secondary
  the Cambridge, 381
  in Central Stations, 305
  Charge Indicators, **434**, **461**
  Cost of Traction, **237**, 495
  Effect of Sodium Sulphate on, 157
  Epstein's, **480**, 592
  FitzGerald's Lithanode Cells, **143**
  Giovanni's, 330
  by J. T. Niblett, **313**, **337**, **371**, **393**, **416**, **434**
  New Plate, C. W. Pike, **432**
  Preservation of, Roux's Experiments, 181
  Salomon's Book on, **94**
  for Traction, 329 (*see* KAPP'S CANTOR LECTURES)
  Tudor and the French Company, 225
  by H. B. Vorley, **551**, **575**
  Waddell and Entz's, **556**
  Woodward's, 82
  Worms's Plate, 496

Becquerel, Prof., Death of, 471
Belgrade Tramways, 449
Bell, Dr. L., Electricity and Steam, **318**
Bell, Dr. L., Theory of Compound Winding, **31**
Bell, Garrett's Magneto, **115**
Bell Ringing, Electric, 615
Bell's Asbestos Company, Meetings, etc., **24**, **176**, **212**, **220**, **247**
Bells, Electric, Catalogue of, 50
Bells, Electric, New Indicator, **192**
Bengal Telephone Company, Meetings, etc., 283
Bennett, J. B., Electric Bleaching, 27
Berend and Co. and their Employees, 401
Berlin Underground Railway, 520
Berly *v.* Challis, **119**, **127**
"Biblioteca Polytechnica," 156
Bidwell, S., Selenium Cells, **22**
Bidwell, S., Steam and an Electrical Discharge, 497
Biggs, C. H. W., First Principles of Electrical Engineering, **95**, **238**, **293**, **344**, 390
Biggs, C. H. W., Loops, Lines, etc., **344**, **390**, **413**
Birkenhead Lighting, 226
Birmingham Electric Supply Company, Meetings, **540**
Birmingham Lighting Inspectorship, 202
Birmingham and Midland Institute, 27, 49, 83
Bishops Stortford Lighting, 543
Blackburn, A. R., Dynamos, **110**
Blackpool Time Gun, 567
Blakesley, T. H., Contributions to Dynamometry, **276**
Blakesley, T. H., Generality of Certain Formulæ, **276**
Bleaching, Electric, J. B. Bennett, 27
Bleaching, Lithanode for, 521
Blizzard, The, 282
Blue Posts Tavern Wiring Tenders, 306
Board of Trade and Overhead Wires, **293**, **298**
Board of Trade and Standards, **164**
Board of Trade Unit, The, 249
Board of Trade and Vestries, **482**
Boats, Electric, 425, 568 (*see* LAUNCHES)
Body, Human, Electricity and, 251, **325**, **349**
Boilers in Philadelphia, Accidents with, 379
Bolton, R., Electric Cranes, **193**, 521
Bolton's Electric Winches, **342**
Bombshells, Aerial, 569
Books, General Remarks on, **92**
Books Received, 25, 155, 281, 495, 568, 615
Bottone, S. R., Electromotors, **95**
Boult's International Wire Table, 28
Bourne and Son, J., Work of the Year, **14**
Boy Messengers' Company and the Post Office, **340**, 377
Bradford Tramways, 251
Bray Electric Railway, **327**
Brazilian Submarine Company, Meetings, **447**, **470**
Brighton Fire and Police Stations, 1
Bristol Lighting, **211**, 249, **262**, 305, 353, 520, 543
Britannia Company's Book on Screwmaking, 427
British Association, Cardiff Meeting, 49, 153, 250, 377, 472, 498
British Association Invited to Edinburgh, 567, 592
British Association Invited to Nottingham, 519
British Ice Company's Works, 594
British Insulated Wire Company's Cables, 105
Brooks, David, Obituary of, **554**
Brooks, David, Oil as an Insulator, **481**
Brooks, David, Underground Electric Work, **19**
Brooks's Underground Mains, **19**, **240**, **254**, 305, **310**

Brush Electrical Engineering Company:
  Alteration in Management of, 129
  Chairmanship of, 401
  City Office, 25, 402, 473
  Meetings, etc., 201
  and Stock Exchange Quotations, **14**

Builder's, etc., Exhibition, 153
Burglar Alarms, Electric, Utility of, 227
Burgling, Electric, 249
Business Notices, 1, **24**, **48**, **104**, 129, 249, 250, 251, 305, 353, 401, 519

C.

C, The Deep, 2
Cable, Atlantic, Reminiscences of the First, **572**
Cables between England and Germany, **123**, 227

THE

ELECTRICAL ENGINEER.

No. 1, Vol. VII. LONDON, JANUARY 2, 1891. PRICE 3D.

NOTES.

Barnsley.—The Council have considered plans for their central station buildings, which are to cost about £3,000.

Naval Exhibition.—Messrs. Willans and Siemens have the lighting of this exhibition. We gave the number of lamps in our last issue.

Refining Copper.—We learn that at Nijni Novgorod, work on a somewhat extended scale has been carried out in the electric refining of copper.

Aberdeen.—A new telegraph wire has been put up between London and Aberdeen. This makes the third wire available for private and trade messages.

Prof. Tyndall.—We are glad to learn that Prof. Tyndall has enjoyed better health lately, and is recovering from the attack of insomnia from which he has been suffering.

Swansea.—The Corporation, acting on the advice of Mr. W. H. Preece, have accepted the tender of Messrs. R. E. Crompton and Co. to put up 23 arcs at a cost of £25 per lamp per annum.

New Zealand Syndicate.—We notice that this syndicate, which was mentioned at the recent meeting of the Gulcher (New) Company, has been registered with a capital of £30,000 in £10 shares.

Society of Arts.—Among the papers down for reading in the new year, but for which no date has yet been fixed, is one by Messrs. H. Newman Lawrence and Arthur Harries, M.D., on "Electricity in Relation to the Human Body."

Exeter.—The Town Council have decided to insert the sum of £30,000 in their order as the amount to be spent on electric lighting works. The town clerk has estimated that the cost of obtaining this order will amount to £300.

The Telephone in Sheffield.—During Christmas week 56,188 messages passed through the Sheffield Telephone Exchange. The total for the 31 consecutive days ending on Christmas Eve was a little over a quarter of a million.

St. Helens (Lancs.).—The Corporation Gas Committee has appointed a sub-committee to consider and report upon the question of the supply of electricity within the borough with a view to its being provided at an early date.

The Telephone in Germany.—It is proposed to run a telephone line between Stuttgart and Frankfort-on-Main. Another scheme on hand is a line running from Cassel through Eschwege, Mulhausen, Sondershausen, and Nordhausen to Berlin.

Edinburgh.—The directors of the Edinburgh Philosophical Institution gave a children's evening on Tuesday night, which was a great success. The proceedings were opened by Lord Kinsburgh, who interested the youngsters in that very interesting subject, "Electricity."

Acme Works.—A West-end showroom has been opened by the Acme Electric Works, in Princes-street, Hanover-square. A complete installation is being fitted up, and a large stock of their fittings, pendants, and the latest and best types of switches are there to be seen.

Telegraph Line Interrupted.—Owing to a fire breaking out in a rag warehouse at Woodbridge, Suffolk, on Monday morning, telegraphic communication between England and India and the Continent was interrupted for about six hours. The wires were repaired in the course of the day.

The (New York) "Electrical Review."—We are informed that the London offices of this journal have been removed from 181, Queen Victoria-street, E.C., to the Hotel Victoria, Northumberland-avenue, W.C., where Mr. Charles F. Ffrench will continue to act as London editor and manager.

Cardiff.—At the meeting of the Cardiff County Council on Tuesday, the town clerk reported that the usual parliamentary notices had been deposited on behalf of the Corporation for an Electric Lighting Bill, the amount of capital to be expended being named at £24,000. This applied simply to the compulsory area.

Brighton.—The Town Council have decided to substitute telephonic for telegraphic communication between the Town Hall and the fire and police stations. Besides effecting a saving of much valuable time, this will also be economical from a monetary point of view to the tune of £55 per annum. At least, so it is stated.

Maidstone.—As the Local Board recently passed a resolution that they would oppose the application of the Electric Installation and Maintenance Company for an order, the company has written saying that in the event of the Board deciding to carrying out the lighting themselves they will be happy to negotiate with them.

Penzance.—At the last meeting of the Town Council a draft provisional order was received from the Board of Trade. This, taken in connection with the Lighting Committee's report, which called attention to the bad quality of the gas and its poor illuminating power, looks hopeful for electric lighting in this pleasant little Cornish town.

Motors at Kensington.—Electric motors are being put in at Barker's Universal Stores, High-street, Kensington. They are driven off the Crompton circuits, and are to be used for chaffcutting, coffee grinding, and other similar purposes. The public use of these electric motors will be likely to lead to their employment in many other places on the circuit.

Gas and Electric Lighting.—Now that the use of the electric light is really spreading, why does not our great gas company push the use of gas for heating? asks Mr.

G. J. Symons, almost plaintively. It's what we want to know, too, for when all is said and done it's about the only thing, besides driving gas engines, for which gas is fit.

Paris.—The Continental Edison Company are building an important electric station in Paris at the Avenue Trudaine. The works are well advanced, and it is hoped to begin supply this winter. Great efforts are being made to obtain the concession for the Boulevard St. Germain for the Ferranti system, as embodied in the Compagnie Nationale de l'Electricité.

Barnet.—Considerable discussion has been going on here as to the cost of the electric lights for the past year. The contractors (Messrs. Joel) make out a balance in their favour as against gas; on the other hand, of course, there are those who turn the figures round and bring out a balance against the electric lights. We are afraid that the net result of all this warfare in print will not be of much use to anybody.

Cleckheaton (Yorks.).—A committee of the Local Board has been appointed to confer with the Town Hall Committee as to lighting that building electrically. A member of the Local Board has estimated that the lighting will cost £1,700 or £1,800, but others think this far too high. The Board and the gas company are at loggerheads, the former wanting a reduction and the latter declining to give it.

Bournemouth.—At the last meeting of the Town Council, the Lighting Committee reported having had before them a letter from the Board of Trade, forwarding the report and balance-sheet of the Brush Electrical Engineering Company. The clerk was directed to reply that the accounts furnished seemed to show that the company were in a position to discharge the duties imposed upon them by their order.

Edinburgh Exhibition.—The liquidator, Mr. J. A. Robertson, C.A., has received a fairly prompt response to his request for payment of the sums for which the guarantors are liable. The guarantee fund amounted to about £26,000, and of that upwards of £23,500 has been received and lodged in the bank. The balance unpaid includes the amounts guaranteed by several corporations, who will no doubt authorise payment at their next meetings.

Foreign Telegrams.—The council of the Leeds Chamber of Commerce have decided to call the attention of the Postmaster-General to the omission made, during the last two or three months, to state upon foreign telegrams the hour and the date upon which they were sent. The omission was regarded as of importance, since the time at which a message was despatched had not unfrequently a bearing upon the price at which goods were to be supplied.

Personal.—We hear that Mr. W. J. Hammer has recently opened an office in New York as consulting electrical engineer. Mr. Hammer came over to England in the old Edison Company's service, and made many friends. He subsequently did a lot of work in Europe. We wish him all success in his new venture. The last time we had the pleasure of seeing him was when he represented Mr. Edison at the 1889 Paris Exhibition, and paid a short visit to London *en route.*

"The Deep C."—The following story may be new to some of our readers. We do not vouch for its accuracy: "The late Dr. Joule, of Manchester, was a welcome, if occasional, visitor to Sir William Thomson, they being old friends, and the story is told that at the period when Sir William was bringing out his sounding machine, in which steel wire takes the place of the ordinary lead line, he showed Dr. Joule a bundle of pianoforte wire, telling him at the same time that it was for 'sounding.' 'What note?' inquired Dr. Joule, not quite understanding. 'The deep C,' promptly replied Sir William."

Vaison (France).—The town of Vaison (Vaucluse) is lighted electrically. The generator is a Zipernowski alternator, with an output of 23 kilowatts, placed some 2·5 kilometres from the town. The pressure in the distributing mains is 1,800 volts. Another small town in Vaucluse is also to be lighted shortly, a 20-kilowatt alternator being used. Vaison has but 3,000 inhabitants. Both these installations have been carried out by Messrs. Lombard, Gerin, and Co., of Lyons.

South African Lighthouses.—The report of the Cape Lighthouses Commission considers that single lights on the coast are dangerous, and that coloured lights should be avoided as leading lights, which should be the most powerful procurable, and should be visible at a distance of not less than 17 miles, and that all the principal lights should be flashing. The Commission also recommends the erection of a lighthouse on Dassen Island, which would give an altitude to the focal plane of light of about 150ft. above the sea level. Electric lights should be wanted for the most powerful lights procurable.

The London and Paris Telephone.—At the end of last week the wires for this line has been advanced as far as Ashford, there being about 25 miles to complete the English land wires. This work is being performed by a corps of the telegraph department men of the Royal Engineers, who number altogether about 60 and work in gangs at different points on the route. There are four wires, constituting two metallic circuits. The Post Office telegraph steamer "Monarch" has been engaged during the week in laying the telephone cable across the Channel, between St. Margaret's Bay, Sandgate, and West Calais.

Abercanaid (Wales).—This little mining village, which is near Merthyr, has been lighted electrically. The initiative was taken by Mr. T. H. Baily, general manager of the Plymouth Collieries, who arranged for the lighting in connection with the Local Board. The necessary apparatus was supplied by Mr. J. C. Howell, of Llanelly. The dynamo is by Crompton, and there are 25 incandescents of 32 c.p. These replace 14 oil lamps, which have hitherto lighted the village, and cost £4. 10s. each per annum, or £63, against £80 per year for the incandescents, of which, however, there are nearly double the number, giving considerably more light.

Photography by Electromagnetic Waves.—From Vienna it is reported that Herr Dombrzynski, of the Lemburg Polytechnic Academy, has succeeded in photographing by electromagnetism. It is also said that he has explained the means by which he succeeded in so doing, in a paper addressed to the Vienna Academy of Sciences. Whilst this success, if true, will be of the greatest interest to scientific men, as throwing further light on the relation between electromagnetic and light waves, we can hardly believe that the present very effective method of utilising actinic rays of light will be superseded in photographic matters by the new method.

Logarithms.—Messrs. Poole and White send us a very handy sheet of four figure logarithms. Anyone who has to calculate out many formulæ knows the value of logarithmic methods, so that into that we need not enter. Not only, however, does the sheet contain a table of logarithms, but a table of the values and logarithms of a number of constants and coefficients that come into electrical calculations, also a calendar for 1891, and a celluloid tablet on which the calculations can be made. The whole is folded into a small morocco case, and can be carried easily in the pocket or pocket-book. Altogether this is an extremely neat and useful sheet.

Newcastle-on-Tyne.—At a meeting of the Town Improvement Committee last week, a deputation from the Newcastle Electric Lighting Company attended with reference to the recent decision of the Council not to sanction an order for a longer period than seven years. Mr. Milburn, the chairman of the company, pointed out that the demand for electric light was so great that their present works would have to be extended, and this, and other matters pertaining to the subject, led the company to express the hope that the matter would be reconsidered, and the time asked for (42 years) allowed. The committee intimated that the application made by the deputation would be considered.

Wood Casings and Rats.—We are informed by one of the best possible authorities on the subject that no rat or mouse has been yet known to have eaten through wood casings in order to get at the conductors therein, although they have gnawed through metal tubes, and injured the insulation of the leads contained in them. Considering that very few buildings are without these mischievous rodents, and in view of the immense amount of damage that may result from their attacking the insulation of leads, we think the above fact is worth knowing. If any of our readers has any evidence to adduce either one way or the other, we shall be very glad to make it known through our columns.

Temporary Lighting.—On Saturday evening last, at the Westminster Town Hall, Messrs. John Broadwood and Sons gave a party to the children of their large staff of employés. The guests numbered about 800, and a feature of the entertainment much appreciated by the youngsters was the illumination of the gigantic Christmas tree with about 90 incandescent lamps, and the hall itself with about 100 more, hung in festoons under the balcony, the wires being covered with holly and other suitable decorations. The current was supplied by the Westminster Supply Company (gratuitously), the temporary lighting being carried out by Messrs. Girdlestone, Tatham, and Co., of Davies-street, Berkeley-square.

St. Louis, U.S.A.—The alternating current electric lighting plant of the Missouri Electric Light and Power Company, in St. Louis, Mo., has grown so rapidly that it has now become one of the largest central station plants of alternating-current electric lighting in the United States. The company was organised in the early part of 1887, with apparatus of a generating capacity of 12,000 lights. This, says an American paper, was the first contract for Westinghouse alternating-current apparatus which had come from St. Louis. Now the company have alternating-current apparatus with a generating capacity of 24,000 incandescent lamps, which makes theirs the largest alternating-current central station plant in America, west of the Allegheny mountains.

Plymouth.—It appears that the work of establishing a telephonic signal station on Rame Head, off Plymouth, is being delayed by the Admiralty, who apparently require a great deal of time to answer the apparently simple question "What accommodation must be provided for the men working the station?" This fearfully difficult task has been almost too great for the good people at Whitehall, and so, although the land wires are up and the cable is ready to be laid, the Western Counties Telephone Company cannot complete the job, because there are no men at the station to work the line. If the Admiralty had had nothing to do with the matter, and everything had been left to Mr. Lewis, the energetic manager of the company, we can confidently say that the line and station would have been working long ago.

Burlington Arcade.—After great discussions, *pros* and *cons.*, wonderings and heartburnings, the Burlington Arcade has at last been lighted by the electric light. The arcade itself is lighted by a row of pendants with white opal shades and 50-c.p. lamps, supplied by current from the St. James's circuit. The light is a great improvement on the few glimmering gas lights hitherto employed. Several of the shops have already adopted the light inside, and all may be expected eventually so to do. The work of fitting up the arcade has been carried out by Messrs. Freeman and Co., of Swallow-street, Piccadilly. It has been long a wonder why such a place should not be lighted by electricity, but the difficulty of getting the numerous tenants to agree on the extra expense involved has, no doubt, prevented it being done sooner.

Glass Insulators.—A significant fact in illustration of the way work goes abroad may be mentioned in connection with the special glass insulators used in Crompton's system of underground mains described elsewhere. When the system was first drawn out on paper, and the design of insulator decided upon, a quotation was asked for from several English firms with a request for specimens to be submitted. Without exception those asked refused to do this unless a definite order for so many thousands was given. At this juncture a German representative called, saw the design, at once offered to submit samples, quickly did so, with the result that orders for tens of thousands of these glass insulators have gone to Germany. Thus does want of enterprise on the part of English manufacturers bring about its own punishment.

The Gas Journals.—The *Journal of Gas Lighting* in its annual review is good enough to say that "the electric lighting industry has, in a sense, prospered during the year." We quite agree with our contemporary, though, perhaps, our sense of the way in which the industry has gone ahead is not its sense. We, however, demur entirely to its statement that "of accidents and fatalities in connection with the coal-gas industry, the year was happily barren." So far as our recollection goes, hardly a week has passed without its record of gas explosions, little and big. The *Gas World*, in speaking of its friendly rival in London, says: "It is not our intention to deny that the electric light has made progress: it has made progress, and that it will make more cannot be doubted; but we think we have had sufficient evidence to enable us to assert that any progress it may make in the future will not adversely affect the gas industry."

Splicing Carbons.—The electric lighting company of Concord, N.H., is using a device by means of which, it is stated, a saving of 30 per cent. is effected in the cost of arc lamp carbons. The trimmers bring to the station all the short pieces of carbon collected on their daily rounds. These are sorted and matched together, to form a carbon about 8in. in length. These pieces are placed in a machine which forms a dowel on one piece and a socket in the other, and they are cemented at the joints. The cement with which they are joined is heat-proof and is a good conductor, so that there is no change in light indicated when the joint is reached. The spliced carbons are used only in the lower holder. Carbons thus joined have, says the *Western Electrician*, been used by the company over a year, and the process is considered entirely successful. A patent for the process has been taken out by Messrs. N. P. Stevens, machinist, and W. A. Richmond.

New Cruisers.—H.M.S. "Sybille," a new cruiser, which has been built by Messrs. Robert Stephenson and

Co., of Hepburn-on-Tyne, was launched last Saturday. She is 300ft. long, 43ft. wide, with a displacement of 3,400 tons on a draught of water of 16½ft. Her engines, which are being supplied by Messrs. R. and W. Hawthorn, Leslie, and Co., St. Peter's, Newcastle, are capable of developing 9,000 i.h.p. with forced draught, and the vessel is expected to be driven by her twin screws at a speed of 20 knots. She is armed with two 6in. guns, six 4·7 guns, nine smaller quick-firing guns, four Nordenfelt guns, and one boat's gun, and there are four torpedo tubes. Incandescents are fitted throughout, and there are powerful search-lights. The Admiralty have given instructions for a new second-class cruiser, to be called the "Charybdis," to be laid down at Sheerness Dockyard during the ensuing financial year. She will be fitted throughout with electric lights.

Telephone Posts.—The county councils and other local authorities seem bent on crusading against posts along the highways within their jurisdiction. Certainly, these posts should be placed where they will inconvenience the public as little as possible; but it should not be forgotten that they support that which is of the greatest possible public utility. A more absurdly selfish reason for not allowing telephone poles to be erected cannot, we think, be found to beat that enunciated the other day at the meeting of the Westmoreland County Council by a member. The Lancashire and Cheshire Company are running a line between Lancaster and Ulverston, and this gentleman did not see why permission should be granted to the company to erect poles because this particular line would not benefit Westmoreland. If reasons like these are to be acted on, good-bye to all the telephonic extensions in country districts which most of us are anticipating in the near future.

Hexham.—At the meeting of the Local Board on Monday a letter was read from the Northern Counties Electric Light Company, asking if the Board would allow them to submit a scheme for the provision of a generating station and plant, distributing mains, etc. They would be willing to provide the Board with all the necessary apparatus, and to go through the necessary forms for obtaining a provisional order for them, and guarantee the Board by undertaking the whole working of the station for a period of years, or until such time as the Board decided to work the plant themselves, the company receiving a portion of the rentals for doing so. In the event of the Board not wishing to undertake the responsibility themselves, they would be willing to rent from them the water power of the old reservoir to be used as an auxiliary power, and to erect on their own behalf a generating station to supply the public and private lights of the district, and, subject to the Board's consent, to apply for a provisional order next session. The matter was referred to the Gas Committee.

St. Pancras Central Station.—The Electricity Committee have issued the following report: "Your committee have inspected the works at the Stanhope-street station, and find the progress in every way satisfactory. With reference to the other works, all of which are being carried out, the engineer has reported that he has tested the boilers of the Babcock and Wilcox Company at Glasgow, and that everything is satisfactory and the work in a forward state. It is also reported that the engines and dynamos are also well advanced. The Electric Construction Corporation raised some question as to the limit of time for their works, and this has been arranged by the engineer, and it is now understood that the station will be ready for them to proceed with their work on April 15 next, and their work is to be completed within two months from that date. In accordance with the terms of the St. Pancras order, plans of the mains have been deposited with the London County Council and the General Post Office, and one month's notice has been given as required to the gas, water, and tramways companies. Your committee have, therefore, every confidence in informing the Vestry that the whole of the works are progressing satisfactorily."

Another Underground Electric Railway.—The promoters of the South Kensington and Paddington Subway Railway Bill, which was withdrawn in the early part of last session, have re-deposited their measure, with important amendments, in the Private Bill Office of the House of Commons, "for the purpose of affording by the construction of subways north and south communication within the metropolis." Power is sought to construct a subway about 1¾ miles long, commencing at a point near the Exhibition-road, Kensington, and terminating in Paddington at the western end of the Bishop's-road bridge over the Great Western Railway. The first directors of the company proposed to be incorporated for carrying out this scheme are the Earl of Kilmorey, Baron Sudeley, the Hon. E. S. Churchill, Sir J. H. Puleston, Mr. J. Irving Courtenay, Mr. Samson Fox, Mr. G. Newman, Mr. E. Power, and General C. E. Webber. For the construction of this subway, in which the motive power to be employed is "electricity or cable power," a capital of £276,000 is sought to be raised, in respect of which the company will be empowered to borrow an additional sum of £92,000. The professors at the Central Institution and the Science and Art Department, South Kensington, do not look with much favour on this scheme, fearing the effect of passing trains on their instruments.

Town Councillors as Gas Shareholders.—This question cropped up at a recent meeting of the Dover Council, and the remarks made by various councillors are instructive. First of all the town clerk read the subsection of the Municipal Corporation's Act referring to the matter. This states explicitly that a member shall not vote upon or discuss any matter in which he has directly or indirectly any pecuniary interest. Plainly, therefore, a councillor who is also a gas shareholder in the town, could not vote or speak on the question of the introduction of the electric light into Dover. Councillor No. 1 said he should get rid of his gas shares in order to qualify as an opponent of electric lighting. Councillor No. 2 thought that this was only an attempt to stop the mouths of the two or three gas shareholders on the Council. He thought it better to take part in the discussion and voting, and chance another member turning common informer. Councillor No. 3 opined electric lighting was too far off for them to trouble about it. The town clerk having stated that breach of the Act he had read was a misdemeanour, and the Mayor having told the meeting that it would be for him to see the law carried out, the subject dropped. Unless we are very much mistaken, breaches of section 22, sub section 3, of the Municipal Corporation's Act are committed by worthy councillors fairly frequently, and with a light heart.

Prof. Ewing.—A few days ago Prof. Ewing, F.R.S., who has filled the chair of engineering in University College, Dundee, since its opening seven years ago, was entertained to dinner in the Queen's Hotel prior to his departure to Cambridge University. After dinner, Mr. G. W. Baxter proposed the toast of the evening, and in doing so gave a brief sketch of the life of Prof. Ewing, stating that he had a most distinguished career as a student at the University of Edinburgh, and that the Japanese Government unsolicited extended the term of his tenure of office of the Chair of Mechanical Engineering in the University of Tokio from three to five years. During the seven years that Prof. Ewing had been in University

College he had done much excellent work both in civil and mechanical engineering, and as an electrical engineer he had made himself a name which would not easily be forgotten. Prof. Ewing, in reply, said he ventured to claim on behalf of his colleagues, as well as of himself, that they had endeavoured to aim high in University College, and if they had not succeeded in getting crowded benches they had at least succeeded in this: that the work which had proceeded from many of the laboratories had received the warmest possible welcome in the highest places, and that their little college, after only six years of existence, had had the official stamp placed upon it, which admitted it to the membership of the family of the universities of this country.

Telegraphic Communication on Our Coasts.—The action of the Plymouth Chamber of Commerce in advocating a more perfect system of telegraphic and telephonic communication between the chain of coast-guard stations around our islands has been endorsed by the Cardiff Chamber. That body has adopted a resolution, which is to be sent to the next meeting of the Associated Chambers in London, affirming that it is most important that, in addition to the coast guard stations, the lighthouses both on the mainland and also on adjacent islands, as well as the lightships, should be placed in communication with the general telegraphic system of the country. The mover of the resolution passed by the Cardiff Chamber (Captain Pomeroy) mentioned that a cable had been laid to connect Lundy Island with the main land, but no provision had been made for its maintenance (? working). The result was that Lundy might be in the Red Sea as far as communication with Cardiff was concerned, as was shown by the fact that during the last gale there were no less than 40 steamers anchored under the shelter of Lundy, and their owners knew nothing of their whereabouts or what had become of them. In one case the underwriters ran up the insurance 60 per cent., and the steamer was perfectly safe under Lundy the whole time. He added that the "Uppingham," which went ashore on Hartland Point a few weeks ago, might have been saved if there had been telegraphic communication between Lundy and Cardiff.

New Insulating Mixture.—A new insulating compound called "voltite" is thus described. It is composed of a mixture of gelatine (specially made), resin oil, oxydised linseed oil, resin, and paraffin. It is cheap, and contains no sulphur. The proportions of the mixture are: Glove glue (*colle de gant*), 1,000 parts; resin oil, 100 parts; oxydised linseed oil, 500 parts; colophane, 150 parts; paraffin, 250 parts. The glue is prepared by taking the refuse clippings of gloves, and soaking them in cold water for one night. The next day they are strained, and washed in several waters until the water is clear. In an iron boiler there are then placed 1,000 parts of water, five parts of carbonate of soda, and dry glove skin 250 parts. This is boiled for six consecutive hours, the water being renewed as it evaporates. The whole boiling mass is next run over a sieve, across which steam is passed to prevent the gelatine coagulating. The boiling solution is received by a wooden tub, through which a current of warm air is passed for one hour. The residue left in the sieve is boiled up with water for three hours, and when filtered can be used again for dissolving the glue, but this time with only 200 parts of glove skin. The gelatinous solution is put into a boiler with the olein or oleic acid used in candle manufacture in the proportion of—gelatinous solution, 1,000 parts; olein, 80 parts. This is boiled for half an hour, after which 10 parts of caustic potash solution (50 parts water) is added. The boiling is maintained for an hour, so as to saponify the olein and form a soapy pulp. The glove glue prepared, resin oil, linseed oil, colophane, and paraffin are added in the proportions above stated; the whole is boiled until homogeneous. This boiling generally lasts about four or five hours.—*Révue Industrielle.*

"The Scot."—This, one of the largest and most powerful steamers yet constructed for the South African mail service, was launched on Tuesday from Messrs. Denny Bros. yard on the Clyde. She has been built for the Union Steam Ship Company, Limited. Her principal dimensions are—length over all, 500ft.; breadth, 54ft. 6in.; depth, moulded, 37ft. 6in. Her estimated tonnage is 7,000 tons. She will be fitted with two sets of triple expansion engines, which, together, are estimated to develop 12,000 h.p. The engines and boilers have been constructed by Messrs. Denny and Co., of Dumbarton, and the dimensions of the cylinders are—two high-press. cylinders 34½in. diameter, two intermediate cylinders 57½in. diameter, two low-press. cylinders 92in. diameter, each engine having a stroke of 60in. There will be six boilers working at a pressure of 170lb. per square inch, and having 36 of Fox's corrugated patent furnaces. The guaranteed speed of the vessel on measured mile, at an exceptionally deep draught, is 18½ knots, or about 21½ statute miles per hour. The "Scot" is built with a cellular double bottom, constructed to contain 1,000 tons of water ballast, and with 14 bulkheads, 10 of which are carried to the upper deck. The first and second-class saloons will be very spacious, and magnificently fitted and furnished, and the numerous cabins of the first and second class will also be unusually commodious and luxuriously fitted. The ship will be provided with about 710 incandescents. The entire ship and machinery have been constructed under special survey by Lloyd's, the Board of Trade, and Admiralty, the latter with a view to her being placed on the list of armed and subsidised cruisers. The "Scot" was named by Miss Giles, daughter of Mr. Alfred Giles, M.P., chairman of the Union Steam Ship Company.

The Big Fire.—In the course of the disastrous fire in Queen Victoria-street on Tuesday, when several lofty buildings were burnt out, a large iron standard carrying 20 or 30 telephone wires crashed through the roof of one of the houses, the wires being of course broken. It seems to us that, sooner or later, we shall have a really bad accident, after the style of America. Luckily none of the wires belonged to light circuits, but there are places in London where such an incident as that of Tuesday might prove a very serious matter. Underground these wires must go some day, let's hope it won't be necessary to sacrifice a life or two before they are made safe in this way. The conduct of the fire brigade deserves a word of notice, though ordinary language will hardly describe the splendid way in which Captain Shaw and his men worked under exceptionally difficult circumstances. The ladders, hose pipes, nozzles, and men were soon encased in ice, and this rendered the work far more difficult and dangerous than usual. The telephone proved, as usual, of the greatest service in bringing up extra help from outlying fire stations. Perhaps nothing could better have illustrated the value of even a minute or two in the case of conflagrations of this kind than the rapidity with which the flames spread from house to house and floor to floor. Without doubt the introduction of electric fire alarms in combination with the telephone has been the means of saving valuable minutes at the very period when they are most precious—viz., the beginning of a fire. We were sorry to see that Messrs. Davey, Paxman, and Co.'s London office did not escape the flames, but this, of course, will not in any way affect the conduct of their business. Another sufferer was the Gulcher (New) Electric Light Company, whose new showroom in Queen Victoria-street was attacked.

ELECTROLYSIS OF SILVER SALTS.

BY ALEXANDER WATT.

In the early days of electroplating many persons engaged in that industry, and a still greater number who were desirous of following the art as a business, made many experiments with solutions of various salts, with a view to obtain practical silver baths which could be used without infringing patent rights then in force. Amongst those experimenters were several licensees under the patents referred to who were desirous, if possible, of freeing themselves from the heavy royalties which their licenses involved. On the other hand, the patentees of certain silver solutions, which they had obtained the exclusive right to use, being desirous of enjoying a complete monopoly of the whole electroplating trade, endeavoured to secure by further patents every available silver solution from which the metal could be deposited by electrolysis. In this way patentees, licensees, and "outsiders" were kept busy in the matter of experiment for some considerable time; but in the long run, with one or two exceptions, the patentees and the holders of licenses got the best of the tussle until, and, indeed, long after, the patents became void by lapse of time.

At the period referred to the preparation of silver baths for electroplating purposes, even in the hands of persons who had deposited the metal on a fairly large scale, was far from being satisfactory, and the trade complaints of "stripping" and other defects were met by a stereotyped reply that "the solutions had got out of order." In many cases those who made up the silver baths possessed but little knowledge of electro-deposition, and were quite ignorant of the chemical principles involved in the art, and the employers had frequently to rely upon the clumsy manipulations of unscientific dabblers, and to suffer the loss and disappointment which each failure necessarily entailed. Discharged workmen—or rather employés, for the terms are not always synonymous—whose knowledge of electro-deposition had been gleaned by the odious system of "prying" into their employer's workshop, or by snatching a sneaking insight into his private note-book, frequently had the audacity to undertake the management of a plating-room, whereas, in many instances, their proper quarters would have been more suitably found within the boundary walls of one of Her Majesty's gaols. As time progressed, however, the beautiful art of electro-silvering, and its cognate arts, electro-gilding and electrotyping, received the attention of scientific observers in this and other countries, and the intelligent practical man soon found that the art, being a purely chemical one, could be more satisfactorily pursued, and difficulties more easily overcome, when a little chemical knowledge was acquired by the operator than when he relied solely upon the "rule o' thumb" system, which had hitherto been his guide.

In undertaking a series of experiments on the electrolysis of silver salts, I purposed, as far as possible, to travel over new ground—that is to say, I desired to ascertain the behaviour, under electrolysis, of various salts of silver not commonly manipulated by the practical operator, and also place under consideration certain silver salts which may possibly be unknown to him so far as regards their electrolytic behaviour. I may further add that in many of the experiments referred to I was desirous of ascertaining whether it would be possible to obtain a useful silver bath without employing the customary solvent, cyanide of potassium. My object in turning attention in this direction was to find out, if practicable, a salt of silver, a solution of which could be used for heavy plating—that is, for depositing thick coatings of silver from liquids prepared without the use of potassium cyanide. An endeavour was also made to obtain a silver bath in which an adherent coating of this metal could be deposited upon iron or steel, and also upon zinc. The experiments were conducted with the current from a modified Daniell battery, as described in former papers, one cell in most instances being sufficient, and in some cases the current was reduced by interposing in the circuit a very thin iron wire. The cathode consisted of plates of polished brass, 3in. by 1in., well scoured each time before using, with finely-powdered bathbrick moistened with water. To each of these plates a copper wire was attached by soldering. The anode employed was, of course, a plate of pure silver. Previous to preparing the various solutions, a quantity of silver carbonate was formed, and this was kept in a moist state in the dark until required for use.

1. *Nitro-Sulphate of Silver by Electrolysis.*—In this experiment an attempt was made to obtain a reguline film of silver from a very weak solution of nitric and sulphuric acids with the aid of a very feeble current. For this purpose four parts of each, nitric and sulphuric acid, were added to 1,000 parts of distilled water, and one Daniell cell, with a length of very fine iron wire interposed between the positive pole and the anode. Under these conditions a cleaned brass plate, being immersed in the solution, received a deposit of silver of a yellowish-brown colour in a few seconds. On rubbing the film with the finger the yellow coating disappeared, but a white film of silver showed upon the surface of the plate. The yellow deposit was doubtless metallic silver in a highly-comminuted condition. The bath was next still further weakened by the addition of 500 parts more distilled water, when the subsequent deposit upon a fresh plate still assumed the yellowish-brown colour after a few moments' immersion, but the film, however, firmly adhered to the plate; when this was removed by scouring, white metal, as before, appeared on the brass surface. An attempt was next made to check the formation of the yellow non-reguline film by adding to the bath, in small quantities at a time, a solution of nitrate of ammonia. The addition of the ammonia salt at first appeared to present some advantage in this direction; after a few minutes, however, the yellow film reappeared, and no modification of the solution by dilution or otherwise, or of the current density, would secure a perfectly reguline deposit of the metal.

2. *Acetate of Silver.*—A bath was prepared by digesting recently precipitated and moist carbonate of silver in strong acetic acid, heat being applied after a time to facilitate the solution of the carbonate. Distilled water was then added to the strong liquid, which was afterwards filtered for use. With the current from a single Daniell, a perfectly black film deposited upon a brass plate immediately after immersion. The solution was then considerably diluted with water, the anode surface reduced, and a freshly-prepared plate immersed, but even under these altered conditions the metal deposited in a black film, beneath which, however, was a perfectly white film of silver.

3. *Acetates of Silver and Ammonia.*—To the above solution was next added a solution of acetate of ammonia, when for a moment deposition appeared to proceed more favourably; in less than a minute, however, the film became dark-coloured and non-adherent, but on removing the loose deposit with the finger the underlying film appeared of the characteristic whiteness.

4. *Acetate of Silver by Electrolysis.*—A weak solution of acetic acid was first prepared, in which was placed a silver anode connected to two Daniells in series; no evidence of electrolytic action being observable in five minutes, three, four, and five cells, respectively, were tried, but it was not until the current from the latter group was applied that any perceptible action occurred, when the brass cathode gradually became coated with silver. After about a quarter of an hour it was found that a copious spongy deposit of silver had formed on this electrode, which, approaching, and eventually touching the anode, short-circuited the current. The plates, at the commencement of the experiment, were placed at a distance of about 1in. apart. The solution was next further diluted with water, the resistance of the fine wire again introduced, but under no circumstances could a genuine coating of reguline metal be obtained. Acetate of ammonia was again tried with the solution, but though this addition at first appeared to improve the character of the deposit, non-reguline metal eventually formed upon the film first deposited, and the solution had therefore to be abandoned.

5. *Citrate of Silver.*—To form a solution bath of this salt moist carbonate of silver was digested in a strong warm solution of citric acid, and the resulting solution, after

filtration, was diluted with distilled water. The current from one Daniell cell was used, when, as in the former case, a black deposit appeared on the cathode almost immediately after immersion. The solution was still further diluted from time to time, but it was not until the bath had become considerably weakened that an approach to a favourable deposit was obtained; and, indeed, this somewhat hopeful condition of affairs soon gave place to the inevitable reappearance of non-reguline metal. Even with the current density greatly reduced, a very small surface of anode only immersed in the solution, and copious dilutions of the liquid, the ultimate deposits invariably assumed the spongy and non-adherent form.

6. *Citrates of Silver and Ammonia.*—A quantity of citrate of ammonia was next added to the foregoing bath and electrolysed under the same conditions. The deposition now took place somewhat more tardily, and a fairly good film at first appeared. In less than one minute, however, the plate assumed a dull appearance, and on rubbing the deposit with the finger it at once became dislodged, and rested on the finger in the form of a grey powder. No further modifications yielded a perfectly reguline deposit, so the liquid was set aside.

7. *Citrate of Silver by Electrolysis.*—In all the experiments with silver salts prepared from the vegetable and other weak acids, it was determined to ascertain what solvent action they were capable of exerting upon the silver anode under the influence of the current. In the present trial, therefore, a rather weak solution of citric acid was first prepared as the electrolyte, in which the anode was placed, and the current from two Daniells in series allowed to pass, a brass plate cathode being used as before. The electrodes were placed about 1in. apart, and in a few moments a black spongy deposit formed upon the brass plate, showing that the acid had attacked the silver anode with some energy. The solution, however, like the preceding, failed to yield other than spongy metal.

8. *Tartrate of Silver.*—In a warm and strong solution of tartaric acid was digested, with constant agitation, a quantity of moist carbonate of silver, and after filtration and considerable dilution, the liquid was electrolysed with the current from a single Daniell, but the resulting deposits upon the cathode were almost precisely similar to those obtained from the citrate. A solution of tartrate of ammonia added to the bath, though presenting some advantages at first, failed to secure an uniform coating of reguline metal.

9. *Tartrate of Silver by Electrolysis.*—In a rather strong solution of tartaric acid, electrolysed with the current from two Daniells in series, the silver anode became freely acted upon, and spongy metal appeared upon a brass cathode very shortly after the immersion of the plates. In other respects this solvent did not yield satisfactory results.

10. *Oxalate of Silver.*—A solution of this salt, prepared by digesting moist carbonate of silver in a strong hot solution of oxalic acid, was tried with the current from one to five cells in succession, but no deposit was obtained until the latter series of cells had been connected, and even with this current only a very slight film of a darkish colour was obtained. A strong solution of oxalate of ammonia was then added to the bath, but this failed to improve the condition of the bath. An attempt to obtain a solution of the oxalate by electrolysis was not successful, since this acid appears to have no solvent action on the anode.

11. *Lactate of Silver.*—To form this solution, moist carbonate of silver was digested in a strong and warm solution of lactic acid, and the solution, after being filtered, was tried with the current from a single Daniell, when deposition was found to take place very slowly; the deposited metal, however, was of a very indifferent colour, and non-reguline or spongy metal ultimately formed on the plate. A solution of lactate of ammonia was then added to the bath, when a thin white film of silver slowly formed on the plate, but was found to be absolutely non-adherent, and was easily rubbed off the plate with the finger.

12. *Borate of Silver.*—A bath was formed as before by digesting moist carbonate of silver in a strong hot solution of boracic acid, the solution being afterwards filtered and diluted with distilled water. With the current from one cell, a white film of silver was at first obtained upon a brass plate, but this was soon succeeded by a deposit of black non-reguline metal. A solution of borate of ammonia was next added to the bath, when the subsequent deposits appeared somewhat more readily disposed to keep in the reguline condition, and still better results were obtained when the solution was further diluted with water. Ultimately, however, the film assumed a less favourable aspect, and non-reguline metal became deposited upon the first coating of reguline metal.

(To be continued.)

THE LATE W. LANT CARPENTER.

We regret to have to record the death of Mr. W. Lant Carpenter, especially as his work was connected with the education of the younger generation of electrical engineers. The school opened by Mr. Lundy, and continued by Mrs. Lundy, has of late years been under the management of Mr. Carpenter and his colleague, Mr. Drugman. That the school has been successful under this management shows that the broad views of the managers were in accord with the requirements of the day. Owing to illness, Mr. Carpenter has for many months taken no part in the management, so that the work of the school will not be interfered with by his untimely decease. The late Mr. Carpenter and the present writer had many and long discussions upon the alterations that were introduced into the establishment up to the time when the present staff was organised, and while, as might be expected, not in agreement upon all points, there existed no difference of opinion upon the main questions under consideration. We found at all times that Mr. Carpenter not only was willing to listen to suggestions, but courted them, seeking arguments for and against till thoroughly satisfied in his own mind that his conclusion was the best. To say that Mr. Lant Carpenter was the son of his father is saying a good deal. Education owes much to the work of these two gentlemen. Dr. W. B. Carpenter reigned long at London University; he was enthusiastic about deep-sea sounding and research, and his son was as enthusiastic in his work connected with university extension.

Mr. W. Lant Carpenter was born in 1841, educated at University College School and at University College. He took a bachelor's degree in science at the London University. The early part of his working life was spent in Bristol as partner in a manufacturing business, but even here his special bent asserted itself, and he was an active promoter of the movement that led to the foundation of University College, Bristol, of which another old friend, Dr. Langton, was registrar. Mr. Carpenter sat on the council for some time as the nominee of the Vice-Chancellor of London University. He took an active part in the Bristol meeting of the British Association in 1875, being one of the local secretaries. He was in charge of the chemical and part of the physical investigations of the deep-sea explorations of H.M.S. "Porcupine" of 1869 and 1870, his report on which was printed in the *Proceedings* of the Royal Society. Having determined to devote himself entirely to scientific pursuits, he removed to London in 1881, and was employed by the Gilchrist Educational Trust in delivering popular lectures to very large artisan audiences upon experimental physics, and mainly upon electricity. One set of such courses, intended especially as a popular exposition of the doctrine of the conservation of energy, was published in book form under the title of "Energy in Nature." It was very favourably received on both sides of the Atlantic, and speedily reached a second edition. His lecture on the "Life and Work of Sir Wm. Siemens," published in the *Gentleman's Magazine*, attracted much attention. He has also lectured to large audiences in America, Australia, and New Zealand. He took an active part in the Universities Lecture Scheme. His death took place on the 23rd of December at his residence, at Harlesden. At the time of his death he was in the fiftieth year of his age.

UNDERGROUND MAINS.—II.

THE CROMPTON SYSTEM.

The system of underground mains used by Messrs. Crompton and Co., Limited, is that of bare strips of solid copper stretched upon glass insulators in an underground culvert, and strained in air from point to point by means of specially constructed straining apparatus. The Crompton system is in use for the low pressure distribution of electricity for direct currents, with or without the use of accumulators, and is principally used upon the three-wire system of mains, though it is also applicable where desired for ordinary parallel distribution. The system has been in successful operation for about four years, and besides the original Crompton central station at Kensington and Knightsbridge, where it was first developed, and where over 12 miles of mains are now laid, it is in use or is being laid for the Notting Hill Electric Light Company, the Westminster Electric Company, at Northampton, at Birmingham, and also in France. Nearly 100 miles of mains in all are now in use or are being laid.

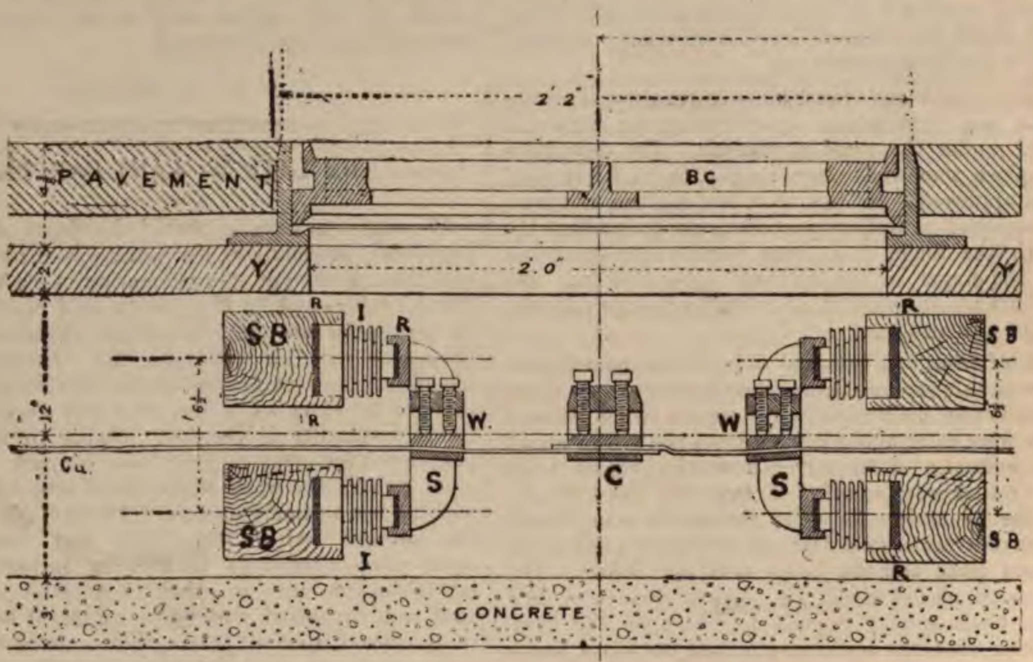

FIG. 1.—Straining Box, showing joint of two copper strips.

In principle, the system may be considered as a return to the ordinary methods of running telegraph wires, but applied to heavy copper mains, and underground. Mains for electric light were originally heavily insulated, afterwards cased in lead, then passed through protecting iron pipes, and finally run in conduits or culverts. To make these culverts such that bare conductors of sufficient thickness could be strained in air—which, after all, is the best as well as the cheapest insulator—thus doing away with costly insulation, has been the aim in the Crompton system, and, in point of fact, this system is one of the earliest attempts at a practical solution of the question of underground distribution on a large scale, and its success has given a great impetus to the planning of central distributing systems.

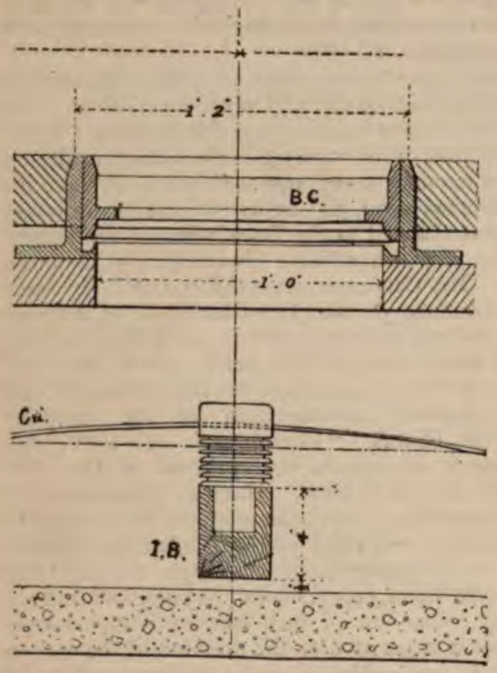

FIG. 2.—Insulator Box—Longitudinal Section.

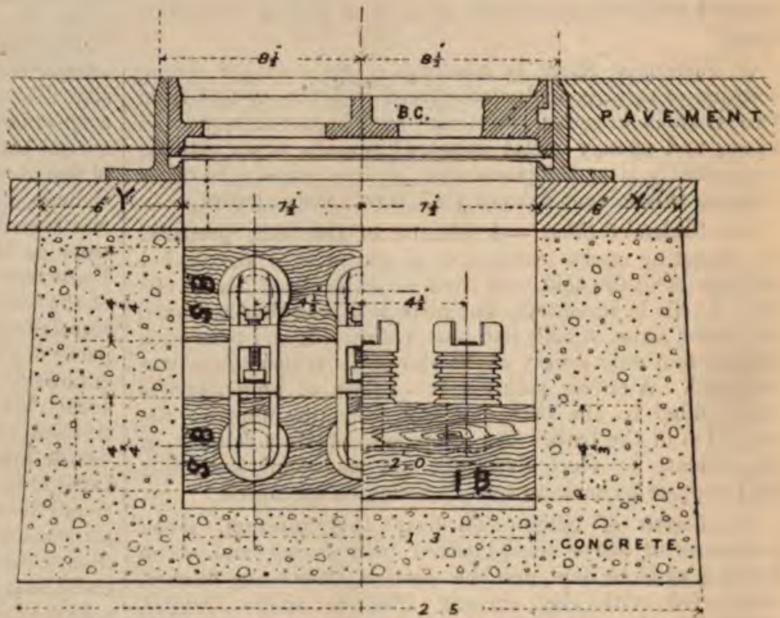

FIG. 3.—Section of Culvert—3-wire mains only.

The development of the Crompton system of electric mains has been, roughly speaking, through the following stages: First, a solid square bar was carried upon a wheel insulator fastened sideways in a culvert, changed afterwards to an upright cup insulator having a slot in its head, carrying first a bar, then modified to a bundle of wires, and again modified to a set of strips placed sideways on their edges. The alteration of the position of the strips, placed next on the flat, brought the method to one much as now in use, its later development being mostly in the mechanical form and the practical method of placing the insulators, and in the system of straining. At first this straining was brought about by the use of a right and left handed screw on the solid copper bars, which drew the lengths together; the alteration was soon made of having each length strained separately, and connected together by a by-pass of solid copper. As at present used, each length of copper strip is separately strained, and the overlapping ends are then tightly screwed together by a screw connecting piece, the strain being taken by specially constructed straining-pieces in the manner hereafter described.

The mains on the Crompton system are made to three standard sizes. These represent (1) the usual three-wire distributing main; (2) the distributing main with one pair of feeders; and (3) the distributing main with two pair of feeders. It is seldom that other sizes than these are necessary; if such cases arise, two separate culverts would be run for the distance required.

The principle of the three-wire system of distribution is now sufficiently well known. With a total pressure of say 210 volts between the outside wires, the pressure between the inner and either of the outer wires is 105 volts. The wires to the houses are connected alternately in such a manner that the number of lamps on one side balances that on the other, so that no current (or only the slight difference between the two halves) is flowing through the centre wire. To keep the pressure the same over all parts of the circuit, feeder mains going to certain determined points where the demand is heaviest, are connected direct from the source of supply, and thus the potential is kept constant.

(*To be continued.*)

LOW-SPEED MULTIPOLAR DYNAMOS AND MOTORS FOR CONTINUOUS CURRENTS.

BY FRANK A. PERRET.

The many practical advantages of a lower rate of speed in dynamo-electric machinery have long been recognised, yet until recently few attempts have been made to secure it. The widespread use of the electric motor has, however, rendered low speed a feature of great importance, in that it so greatly simplifies the application of the machine to all classes of work, in most cases obviating the necessity of countershafting or similar speed-reducing mechanism.

The writer is aware of a prevailing opinion that serious difficulties are encountered in the attempts to manufacture this class of machines on a commercial basis, but believing the difficulties to be surmountable he devoted several years to a careful study of the subject, with the result that he designed a type of machine in which he believes the desired end is attained without the introduction of any element of danger or the sacrifice of a single feature essential to a thoroughly practical machine.

In the light of this experience it is proposed to consider briefly some of the principles which govern the action of multipolar machines, and to demonstrate that the obstacles which have heretofore stood in the way of low speed may be, and have been, overcome.

The prime function of an armature conductor is the generation of an E.M.F., the value of which is proportionate to the number of magnetic lines of force cut by it in a given time. Now, the number of lines cut per second is dependent upon two factors, (1) the total number of lines of force in the magnetic circuit, and (2) the number of times they are cut per second. As our aim is to generate a given E.M.F. at a lower speed than is usual, it is evident that the quantities in either or both of the above factors must be increased. In the case of the first we are limited by the saturation point of iron which prevents our indefinitely increasing the strength of the magnetic circuit without adding abnormally to the weight and size of the machine, and even were it possible to do this, an increased exciting current would be required, which would detract directly from the total efficiency. We turn then to the second factor and, paradoxical as it appears at first, it is here we find the solution of the problem. How are we to cause an armature conductor to cut a given number of lines of force a greater number of times per second without increasing the speed? In the ordinary two-pole machine the armature conductor crosses the magnetic circuit and cuts all the lines of force twice during a complete revolution—viz., where they enter the armature core at one pole and where they leave it at the other. Now, if we so dispose the magnetic circuit as to cause the lines of force to enter the armature core at one point, to leave it at another, to enter it again at a third point and to leave it at a fourth, it is obvious that the conductor will cut all the lines at four points in each revolution, and that it will therefore generate the same E.M.F. at one-half the original speed. If we increase the number of poles to six, we shall obtain the same effect at one-third the speed, etc. This, then, is the principle of construction by which we secure low speed.

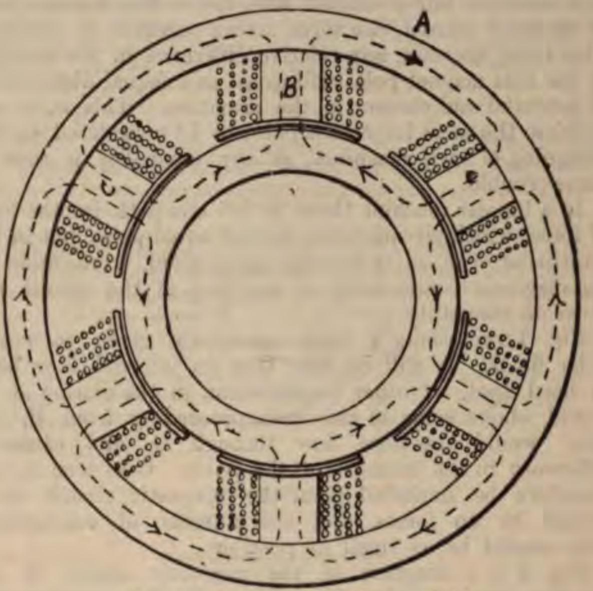

FIG. 1.—Ordinary Multipolar Field.

It should be noted that we do not increase the number of lines of force in the magnetic circuit, we do not add to the turns of wire in series on the armature, we do not increase the amount of either copper or iron in the entire machine, but we simply cause the armature conductor to cross the magnetic circuit as often in one revolution as it ordinarily does in two or three revolutions, as the case may be. The writer wishes to emphasise these points as there seems to be some misunderstanding in regard to them. We do not wind an armature to run slowly, but we design the machine for low speed. The resistance of our armature is no higher than that of a high-speed machine of the same power, its current capacity is not reduced; in fact, as we shall see later, it is increased. The efficiency is no lower, the regulation no less perfect, and the weight and bulk no

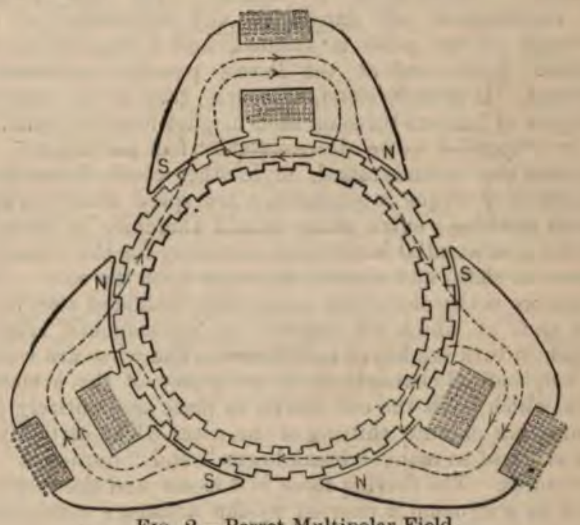

FIG. 2.—Perret Multipolar Field.

greater. We see, then, that in theory the multipolar machine is perfect; consequently, if any difficulties have been encountered in its practical operation they must be due to some faults of construction, to a consideration of which the attention of the reader is now invited.

If we take as an example a motor having a six-pole field, and imagine the same in action, we see that the distribution of potential is such as to form the equivalent of three ordinary armature windings on the one ring and connected to the commutator, which has three times as many segments as that of a two-pole machine. Each of these windings—*i.e.*, the wire lying under one pair of poles—has exactly the same number of turns as an armature of a two-pole machine, but of smaller wire, and carries but one-third of the total current, the three acting together in multiple. This being the case, any relative difference in the strength of the field magnet poles will cause an unequal distribution of potential and current in the armature. This is, in my opinion, the most important point to be considered in the designing of such machines, as any inequality is sure to cause trouble.

In a bipolar machine there is but one path for the lines of force, which circumstance ensures equal poles, but in the multipolar type, as ordinarily constructed, a variation in the magnetic conductivity of any part of the circuit will cause an inequality.

Fig. 1 represents a form commonly given to multipolar fields. It will be seen that an internal blow-hole, or hard spot, or other imperfection in the casting at A, would choke some of the lines proceeding from B, and they would therefore flow through C, and cause a difference in the strength of the poles. Cast iron should therefore be excluded from the magnetic circuit, there should be no joints, and the number of magnetising coils should be as small as possible.

Fig. 2 is a diagram of the magnetic circuit of the machine designed by the writer. In this construction there are but three magnets, each being isolated magnetically from the others excepting through the medium of the armature core, and completely isolated from the framework of the machine. They are formed of plates of soft sheet iron, which are punched to the required shape and strung together on non-magnetic bolts by which they are secured to their supports. A single magnetising coil forms two salient poles, and as each magnet is built of a large number of plates a uniform magnetic conductivity is secured. By this method of construction all danger of any inequality in the strength of the poles is avoided, and a magnetic circuit without joints and of the lowest possible resistance is secured. It is understood, of course, that in all cases the number of ampere-turns on each magnet must be equal.

In proportion as we decrease the "feet per minute" we increase the "pounds raised," or, in other words, the mechanical effort or torque is greater in a low speed than in a high speed machine; extra pains should therefore be taken to secure a substantial mechanical mounting for the armature upon the shaft, and also for the wires upon the core. The armature is therefore built up on eight insulated steel bolts, the ends of which are secured to non-magnetic spiders, which in turn are keyed to the shaft. The wires are wound in longitudinal channels on the periphery of the armature core, which holds the coil rigidly in place and entirely prevents that minute shifting of the wires which certainly is the cause of so many "breakdowns" and "burn-outs" in armatures. The driving force in a motor and the resisting force in a dynamo is exerted by the armature conductors, and we should always provide a positive mechanical connection between them and the core; friction does not suffer. The importance of this point is fully understood by Kapp, who writes: "In many machines the friction produced by the binding hoops is alone relied on to carry the wires through the field, but experience has shown this to be insufficient. Even if the wires are not bodily torn off the armature by the magnetic resistance of the field, they shift and work on the surface of the core; and it is only a question of time when the insulation will be destroyed, and the machine break down."

We have a choice of two methods of coupling the armature circuits together in multiple, one of which is by the use of six brushes distributed around the commutator 60deg. apart, three negative and three positive, and the other consists of a system of cross-connections in the armature or commutator, which connects those coils which are simultaneously undergoing the same induction; these in a six-pole machine are situated 120deg. apart. By this means a single pair of brushes suffices, and these bear on the commutator at points diametrically opposite, exactly as in a two-pole machine. This method is preferred when copper brushes are used, and I have in use a simple system of cross-connections at the back of the commutator, in which all danger of short-circuiting is avoided; but the carbon brush is so peculiarly adapted to the method just described that it forms one of the simplest and most reliable means of commutation that can be devised. The high resistance of the carbon brush, as ordinarily constructed, has prevented its universal adoption, but the construction of this machine permits the use of three pairs of brushes, each pair carrying but one-third of the total current, and the resistance is greatly reduced by reason of the increased contact surface.

In a two-pole machine the armature current is divided equally between two circuits, while that of a six-pole machine splits into six. This the writer considers in most cases an advantage, as the current-carrying capacity is increased by reason of the greater surface exposed to radiation, and the machine will consequently bear a greater overload without injury, while the wire is not so large as to be unmanageable. In many machines of the two-pole type a stranded armature conductor must be used, because a single wire would be too stiff, and would heat too much; in a multipolar machine these troubles are avoided.

A great deal has been said and written in respect to the difference of potential that should be allowed to exist between adjacent commutator segments, some writers having advanced erroneous opinions on this point to the disparagement of multipolar machines. One tells us that 10 volts should be the limit because "10 volts will just form an arc," while another puts the limit at 19 volts, and gives the same reason.

Now, an arc has to be started or "drawn," and the only time this can happen is when the brush connects two adjacent bars as they pass under it. But this only takes place at the so-called neutral points, where the difference of potential between adjacent bars is almost nothing. Theoretically, this difference of potential is simply the product of half the total current and the resistance of the coil connected to the two bars. We see, therefore, that we should not take for a basis of calculation the average difference of potential between adjacent bars, for the reason that the E.M.F. of each coil is continually varying from zero to maximum, and down to zero again. A very clear description of this action will be found in the fourth chapter of S. P. Thompson's "Dynamo Electric Machinery," together with the methods used in determining it, and I commend a perusal of this to the writers referred to.

In a machine wound for 220 volts and having 22 coils acting in series, we do not find a uniform difference of potential of 10 volts between adjacent commutator bars, but those coils which are passing the poles are generating 15 or 20 volts, while those in the neutral zone are generating practically nothing. In some of the most widely-used closed-coil machines in this country the average difference of potential between adjacent segments is far greater than the limits given by the above-mentioned writers. In one of these it is 27 volts, in another 50 volts, and in others it is still higher, yet these machines give no trouble whatever.

Let me not be understood to favour the use of a small number of commutator's sections, I simply wish to show that no one is limited to 10 or 19 volts average potential difference between adjacent bars.

In the machines of my own design which I have partially described, the number of sections in the commutator is 96, of which 16 act in series. At an E.M.F. of 220 volts they average, therefore, 13¾ volts each, and at 500 volts total E.M.F. they will average 31¼ volts.

As bearing upon some of the statements which I have made I present the following details of 10 and 20 h.p. machines, which fairly represent them all.

10-h.p. 220-volt motor.
  Speed, 600 revolutions per minute.
  Weight, 900lb.
  Resistance of armature, ·19 ohm.
  Resistance of shunt, 175 ohms.
20-h.p. 110-volt dynamo (compound).
  Speed, 600 revolutions per minute.
  Weight, 1,300lb.
  Resistance of armature, ·029 ohm.
  Resistance of shuut, 26 ohms.
  Resistance of series coil, ·007 ohm.

It will be seen that a low-speed multipolar machine is not necessarily a heavy one, but that, on the contrary, it may be made very light. The writer has recently built several 25-h.p. series wound motors, which weighed 1,300lb. each, and ran at a speed of 500 revolutions per minute. If one of these were so wound as to run at 1,000 revolutions per minute, it would develop 50 h.p., and weigh only 26lb. per horse-power. For traction purposes these motors are designed to run as slow as 450 revolutions per minute, and weigh about 70lb. per horse-power.

In regard to their practical operation, I will simply say that the first machines which were constructed a year ago have been in constant and satisfactory use ever since, and they have proved themselves to be in every respect the equals of the high-speed machine.—*Electrical Engineer* (New York).

INDUCTANCE AND ITS PROPOSED UNIT THE HENRY.[*]

BY A. E. KENNELLY.

Perhaps the greatest discovery of Faraday's long career of scientific research was that of electromagnetic induction in the year 1831, when he first brought to light the influence exerted by a magnet or a current upon surrounding matter when subjected to a change of magnetic potential. Oersted had shown that a conductor carrying a current exercised electromagnetic influence at a distance, and Ampère had enunciated those simple and beautiful laws this influence is admitted to obey, but Faraday's discovery was a great step—it revealed the action of magnetic force in apparently empty space; it inaugurated that deeper insight into the mechanism, still only dimly guessed, which connects matter with all other matter in space, and it invested the all-pervading ether with a dignity and power that in the hands of many great men since his time has probably paved the way for our future comprehension of magnetism, gravitation, and radiant energy, while making the hypothesis of action at a distance a mere mathematical conception and process of thought.

The development of this discovery of electromagnetic induction has practically created electrical engineering, for it is to machinery operating by electromagnetic induction that we owe nearly every branch of electrical industry, except, perhaps, telegraphy, the forerunner of all; and the condition of modern electrical engineering is such that the units and nomenclature relating to steady currents and permanent magnets is insufficient for practical requirements, and the conditions developed by variable currents and magnets demand the establishment of engineering practical units for the purposes of convenience in expression and computation.

Foremost among these required units is that of inductance, or, as it is commonly called, the coefficient of induction. This induction is a property fully as essential to every electric conducting circuit as resistance and electrostatic capacity, and the inductance of a circuit when conveying variable currents is often a far more important factor in regulating the flow than the ohmic resistance. In fact, we know that Ohm's law does not apply to a circuit so long as the current is unsteady, unless the inductance of the circuit or the counter E.M.F. it involves be introduced into the expression.

In conformity with the conventional and so-called absolute units of electromagnetism, an inductance is a length, and theoretically can always be computed from the geometrical relations of a circuit; that is to say, if the distance of each point from all other points of a circuit be measured, or inferred, in inches or centimetres, the inductance of the circuit will be some definite number of inches or centimetres, capable of being determined by a possible if not a convenient process of summation. If the circuit, however, be associated with iron or other magnetisable matter, then the magnetic permeability of the environment will enter the terms of summation as a multiplier. In the absolute centimetre-gramme-second system of units, inductance will be necessarily expressed in centimetres, and the centimetre is thus the natural scientific unit, although unsuited to the requirements of electrical engineering.

It may be well to notice that inductance is only conventionally, and, perhaps, not essentially, a length. Prof. Rücker has pointed out that the multiplication of the permeability factor with the length factor is always tacitly, if not expressly involved, even when the circuit considered is far from magnetisable matter in the ordinary sense—that is to say, when residing in a medium of unit permeability—and, therefore, the nature of inductance is not merely length, but length multiplied by permeability, while physics has not yet decided whether permeability is the simple numerical factor at present assumed, or a function of length, mass, and time. Until this question is settled, the real nature of inductance must be considered as doubtful, and the fact that inductance will probably, in any event, be always measured by lengths is no more validly an argument as to its nature, than the usual determination of a body's mass by the earth's gravitational force upon it is an argument that mass is a force. However, the question is one of theory only, and does not affect the consideration of the practical unit.

As has been pointed out by Dr. Sumpner, there are no less than three ways of defining the inductance of a circuit, or a portion of a circuit, and the three definitions are equivalent when the permeability of the magnetic medium is unity, but are not generally equivalent in the opposite event, being then only related in a definite manner by the magnetic properties of the medium. In other words, the inductance of a hollow solenoid of copper wire, placed in a vacuum and far from all iron, has the same numerical value in each of the three definitions, but if an iron core be inserted in it, its inductance will depend upon the definition selected, and will only be capable of interpretation from its value in one to its values in the others, by taking into account the characteristic permeability curve of the iron, and the conditions of the measurement.

The inductance of a circuit, or portion of a circuit, is then the ratio between the total induction through it to the current producing it. Thus taking a simple helix of five turns carrying a current of two units, and assuming that 1,000 lines of force[*] passed through the central turn, of which, owing to leakage, only 900 thread the next adjacent on each side, and again only 800 through the end turns, there would be 800+900+1,000+900+800, or 4,400 linkages of lines with the wire, and this being with two units of current there would be 2,200 linkages with unit current, and consequently the self-inductance of the helix would be 2,200 centimetres. Fig. 1.

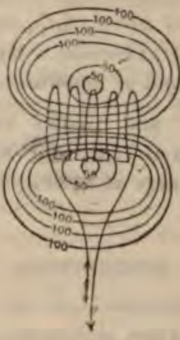

FIG. 1.

The fact that such helices are used in galvanometers, and that the magnetic force at any point with them is admitted to be proportional to the strength of the traversing current, renders it evident that had the current in this case been one unit, 2,200 lines linked with the coil would actually have been produced. Supposing, however, that the helix had been wound upon an iron core, the total number of linkages with the same two units of current would have been greatly increased, perhaps twentyfold or to 88,000, and the inductance then by the same rule would be 44,000. In this case one unit of current would not in all probability reduce the number of linkages to 44,000, the exact number would depend upon the characteristic curve of the iron core and the degree of saturation, so that it would now be necessary to state the conditions of the measurement along with the result in order to convey a clear and definite meaning.

It appears anomalous at first sight to state the above inductances in centimetres when they are derived from the number of lines of force, but it is to be remembered that the total number of linkages is divided in each case not by a mere numeric, but by a current, and this quotient can be proved to be a length in the existing system of dimensions.

In the same way the mutual inductance of two conductors is the ratio of the total induction through one of them to the strength of current in the other producing it. Suppose two coils of copper wire to be held in free space far from iron, and let one of them be traversed by a steady current of, say, four units. Of all the lines of force issuing from this coil, suppose 500 pass through the other coil. For simplicity, imagine the second or recipient coil to be composed of eight turns so disposed that the 500 lines pass through all in succession. There will then be 4,000 linkages of lines with that coil, and the mutual inductance of the two will be 4,000 ÷ 4 or 1,000 centimetres. It is interesting to notice that the same result would be reached if the second coil had the current and the linkages were counted in the first, the pair being mutually conjugate in this respect, provided they reside in a medium of constant permeability.

(*To be continued.*)

IMPORTANT NOTICE.

We may occasionally follow the lead of our American Contemporaries, especially when they point out a serviceable way. They are not backward in asking their friends to do all they can for the welfare of the paper. We ask our friends to remember us. No Paper that we know ever refuses Subscribers or Advertisers. Nor do we; in fact, we invite them, believing that they will get full value for their money.

Specimen copies of the paper will be sent on request.

1891.

MAY IT BE TO EACH READER A HAPPY AND PROSPEROUS YEAR.

It has been our custom in the first issues of the year to obtain from various firms and companies interested in the industry a *résumé* of their work during the year, and an expression of opinion as to future prospects. That many of the names appear year after year is but a proof of successful enterprise and the survival of the fittest. Here and there a firm as it increases in age increases in conservatism, and while in earlier days, with the blood coursing more swiftly through its veins, its business instincts were stronger, and more eagerness was shown to make a name and establish a record, it, as it grows older, seems content to linger out a respectable life. Such firms exist, but most emphatically they will be outstripped in the race unless they think less of what they have done and more of what they should do. In business, as elsewhere, he who ceases to be aggressive ceases to be progressive. The time has long since passed when business came in because a sign was hung out. New firms are rapidly springing up, determined to have their share of business, and sometimes leaving the beaten path of success too far behind in their eagerness to snatch work from competitors. Still, on the whole, the tendency is upwards as regards the character of the work done. Perhaps some readers may demur to this conclusion, and doubt the accuracy with which insurance companies can gauge this kind of work. They are welcome to their opinions. We think otherwise, and put a question as to character of work now done compared with that done in past years to a gentleman who probably sees more electrical work than any other man living in these isles, and the answer was: "The work now done is distinctly better."

The danger to electrical work is twofold—bad workmanship, and what old women in Buckinghamshire call "scrimping." In previous years we have had our say as regards bad workmanship, and now pass it by in the hope that the improvement may continue, but the "scrimping" must have a word. The fear of Mr. Hartnell is in our eyes, and no doubt he will declaim with piquancy and pungency at the ignorance of technical writers, when we say it is a mistake, and a great mistake, to be too niggardly with copper anywhere. It is all very well to answer that calculations have shown this or that section to be sufficient to carry the proposed current. Calculations prove a lot of things that experience says are nonsense, and in this age of calculations they are too often made the vehicle of schedules of prices which allow no margin for contingencies or for factor of safety. The young firm especially, whose experience has yet to be bought, tenders upon calculations which leave no margins, and no one of greater experience is surprised when they have to pay for their wisdom. Take it as scientifically doubtful, but take it as a matter of fact, that deterioration of work and material does take place, and that if satisfactory and permanent work is to be done such deterioration must be allowed for. Niggardliness with copper in wires means also greater cost of and loss in working; in machines means failure, trouble, and any amount of disputes.

When we come to consider the business problems that await solution to-day, we find that they are very similar to those awaiting solution a year ago. Men are, however, beginning to see that some of them are insolvable. The distribution from central stations, what shall it be—high pressure, low pressure, by alternate currents and transformers, or by continuous currents and batteries, shall the three-wire or n-wire of any specific system of distribution be adopted? The answer is, or should be, that each system has its place, and one will be preferred here, and another there, according to surrounding circumstances. By the way, is there any reason why "transformers" or "converters" should have a specific name? They are alternators in every sense of the word. The generating alternator at the central stations transforms upwards. The converter is an alternator transforming downwards. Where is the insuperable difficulty of building generating alternators on the same lines as transformers? Faraday gave us two types of alternators; and even with all the eulogies bestowed upon him, his devices have never been sufficiently widely recognised as actual typical machines. Faraday also gave us the means to construct a workable theory of a simple character, which has since been so overladen with high-sounding terms and unnecessary mathematical interpolations as to frighten students. Any mechanical engineer with an ordinary education may in a short time learn all that is necessary to enable him to construct dynamos which have as great a commercial efficiency as any dynamo ever constructed by the most learned professor. We do not for a moment disparage the investigation of minute points; but so far as dynamo building is concerned these minute points are almost valueless. We want thoroughly sound mechanical education first, and then the electrical. This is what parents do not understand, and what it seems to be the aim of some people to hide. Nine-tenths of electrical work in lighting and power distribution is purely mechanical engineering, and if a man wants to succeed he had better know less about hysteresis and more about mechanics. Electricians are not so much wanted in the world as are electrical engineers. The latter are wanted, badly wanted, and the future lookout for them is particularly healthy. Once more, then, we urge young men not to be frightened away because the subject seems so transcendental. It is not. Put on the slops, go through the shops, and you will find plenty of work. On the other hand, if you are afraid of a little clean dirt, and think overmuch of pretty instruments and pretty calculations, the field is full, and you are not wanted in it. We are well aware that our standpoint is contrary to that of many well-meaning but ill-informed people; it is the result of experience. All men can't be gentlemen and wear kid gloves because they have heard of "Ohm's law," and have read extensively the electrical literature of to-day. Thomson, Thompson, Ewing, Forbes, Kapp, Hopkinson, Lodge, and a dozen others have done and are doing grand work, but where there is room for one of these there is necessarily room for 500 of a different class. Many, too, of the latter make bigger incomes than the former.

To return to the question of distribution. Last year we said all eyes were turned towards Deptford. What was said then may be said again, and the more so because some of the gas journals, with their more than bitter antagonism and utter disregard of facts, are trying to damn the work of Mr. Ferranti. Our sympathies have always been in favour of continuous currents, because we think "power" more than "light" must become the cry, and the supply of both should be equally simple. We are told that alternate-current motors are ready whenever they are wanted. If that is so—and there is no inherent reason why it should not be so—one objection to alternate currents is gone. But as regards Deptford, the system has not been tried. The time to stop work passed as soon as work commenced. The old axiom that "faint heart never won fair lady" should be the maxim of the London Electric. They must proceed, and they must succeed. Theirs is not the first company that has passed through a slough of despond, and, goodness knows, their slough at the moment must be bitter enough. Beset by virulent enemies, who stick at no mean trick to undermine the company, the friends who should support them are very lukewarm in their praise, and, like politicians, sit upon the fence to watch which way the cat jumps, or the better to give an unseen push downwards. It is the way of the world —kick a man if you think he is down.

It has been said that our advocacy is from interested motives. To this we might reply in the language of Bret Harte. Most of our readers have read his poem on number "Seventy-nine"; if not, the best thing they can do is to read it at once, and picture us as "79" and Mr. Ferranti as the other party. To us Mr. Ferranti and the London Electric are in the position of men who have undertaken, after due consideration, engineering work of the utmost importance. They have to encounter difficulties in the progress of the work, as all thoughtful men must have expected. They have met them, met them bravely, and over and over again have encountered them successfully. A chapter of accidents had also to be met, and for the moment floored them. That does not spell failure, for as yet the system has not been on trial. It does not mean, however, that the sympathies of fellow-workers ought to be withheld, unless from the very first there were known scientific or practical reasons pointing to the impossibility of success. We challenge any competent man to support any reason of this kind. We say there exists no such reason. In a word, Mr. Ferranti has had our consistent support because we can see no reason why his proposed high-pressure distribution should not be successful.

It may be well here to refer to another matter which is important—viz., Stock Exchange quotations. A careful examination of such quotations will show that they are not real indications of the status of a company. They may be indications of how well certain wire-pullers can engineer and finance matters to their own benefit. We are quite ready to prove that certain quotations have no solidity, and it is almost as certain as anything mundane can be that some shares quoted at higher values are not really so valuable as those quoted at lower rates. Time will prove whether our instincts are correct, and we fancy will, by a turn of the wheel, show shareholders that "finance" is not in the long run as good as "work." Let us venture to prophesy. Old Father Brush has had a chequered career, but its shares are now quoted at too low a price, and twelvemonths hence investors will wonder why on earth they could not see it. But, as we say, the quotations are merely financial; few transactions take place. Those who hold some of the lower quoted shares are quite prepared to hold and to wait the proper time. In several cases they are certain to reap a rich reward. Of course our surmise contains the proviso that business continues to be conducted upon the same keen lines as at present. Men there are connected with some of the more prominent companies who could not well be matched even with Shakespeare's witches to mingle Greek, Scotchman, and American in the best proportions to ensure perfection in 'cuteness. It is these men who are gradually restoring confidence in the investing world, though they have a hard task to counteract the Machiavellian customs of the mere gambling promoter and speculator.

Two questions we have recently discussed will become more and more pressing. These relate to fluctuations of pressure in supply from central stations, and to actual rather than nominal candle-power supplied. We have recently seen a gas company fined for not supplying gas up to standard. It is certain that consumers of electrical energy will not be placed in a worse position than the consumers of gas. Pressure ought never to fluctuate more than 1 per cent., and lamps ought never to give a less light than 1 per cent. below the candle-power they are supplied and supposed to give. These are rigid conditions, my masters, and you say they cannot be complied with. Why not? Engineers and millowners long ago came to the conclusion that the proper way to provide for the working of mill machinery is to have plenty of power. And how often we hear the remark that such and such a mill should have an electrical installation because there is plenty of waste power, so no cost in that direction would be involved. Whether is it easier to regulate pressure when you have it in plenty and to spare, or to regulate when it is calculated so closely that under ordinary circumstances no difficulty arises, only under extraordinary? Will suppliers of electricity have to learn what they ought to know already, and that is, Englishmen kick up a fearful row when the extraordinary times come, and you may do almost what you please in ordinary times?

The plan of systematically keeping the pressure at the minimum point allowed by Act of Parliament, when lamps to give normal candle-power require normal pressure, means dissatisfaction. The electric light is not installed to have less light than with gas, but rather, if not more, to have the same light under healthier conditions. You promise 8 or 16 candles and you give 6 or 12 candles. Is this the way to succeed in business? We trow not, and though luxury or fashion may put up with inconvenience for a time, the mutterings are beginning to be already loud and deep, and from quarters, too, that will not hesitate to strike and strike hard if not attended to. While suppliers must look to their production, lamp-makers have also their part to play in providing proper apparatus. Lamps deteriorate, and sometimes rapidly. It is not a question now, has a lamp lasted 11,000 or 14,000 hours, but how many hours will it give with normal pressure the candle-power it purports to give? At one time "lasting" was a lamp test. It is so no longer. We know that lamps can be made to last a thousand or more hours, but lamps are constructed to give light, and unless they give normal light they cannot be reckoned as perfect lamps.

We will now adjourn further general remarks to glance round the prominent firms and companies in the industry.

Joseph Bourne and Son have during the last season been exceptionally busy, the demand for their vitreous stone insulators and battery jars being unprecedented.

Crompton and Co.—The output of this company in all classes of work has been about double what it was the preceding year. The heaviest portion of the work has, of course, been in connection with central stations, of which we may name the Kensington and Knightsbridge, the Notting Hill and Westminster Companies in London; the Birmingham Electric Supply Company; Northampton, Southampton, Chelmsford, Swansea, and other towns. The company have increased the quantity of mains laid on the Crompton culvert system, until at the present time there is nearly 100 miles either in use or ready for use. A detailed account of this system, amply illustrated, commences in our issue of to-day. Messrs. Crompton and Co. executed a contract for an electric railway for the Southend Local Board, in a remarkably short space of time, in the course of last summer. This line has been working ever since, and has given very great satisfaction, and is, we believe, a very paying investment for the Local Board. Great strides have been made in the manufacture of dynamo machines. The average of three 200-h.p. machines recently supplied to the Birmingham Company has shown a commercial efficiency reaching 96 per cent., which the firm believe is a record of the highest results obtained by any makers. The extremely high efficiencies obtained by them and other makers are supposed to be principally due to the use of the patent twisted and compressed copper strand armature conductors. Most of the leading firms are licensed by Messrs. Crompton and Co. to use this invention, and in every case they have found enormously increased efficiency from the use of it. They have made a great many sets of electrical transmission plant for pumping and haulage in collieries. This company has been surprised to find that they are able to compete with American manufacturers of electrical machinery in their own country, and have sent out a good many sets of machinery to that country, although they have to pay a 45 per cent. import duty. As regards the foreign business, the Australian Company is very full of orders. One of the managing directors, Mr. Albright, is visiting that country, and hopes to secure the lighting of some of the largest towns, as the company has already lighted some of the smaller ones. The increasing difficulty of obtaining accurate tests of the various materials used in the business led Mr. Crompton to establish a very complete testing laboratory at Kensington. This is fitted with large accumulators, and all kinds of apparatus for the testing of copper, iron, efficiency of batteries, efficiency of dynamos, arc lamps, or arc lamp carbons. The great increase of London work has necessitated the building of a London works at Lillie-road, Kensington. These works, which were only started in the summer, have been kept fully employed up to the present, and appear likely to be so for a long time to come. In many cases there are reasons why definite information cannot be given, but we have indicated sufficiently the variety of work carried on by this firm. Thus, in electrical transmission of power, work has been done at Pleasby Colliery, at Southend, at Stanton Iron Works, and we hope to see this class of work extend in the near future very largely. Electric lighting has been carried out on a large scale from various central stations, and a considerable number of private installations.

Drake and Gorham.—The increase of business during the past year has been so marked that Messrs. Drake and Gorham have been compelled to make constant additions to their staff, and to extend their offices and stores. The number of installations carried out has exceeded the record of any previous year, clearly showing that there is still plenty of work to be done in isolated plants, in spite of the adoption of central stations. The installation at the new police buildings is now at work, and is to be completed during January, by which time the current will be available for 1,500 lamps of 16 c.p. The lighting of the exhibition at Madame Tussaud's has been working successfully for some weeks, and the firm have introduced the light to a large number of country mansions, amongst which we may mention those of Alexander Henderson, Esq., Buscot Park; Reginald Corbett, Esq., Adderley Hall; G. Singer, Esq., Conndon Court; W. Hemmant, Esq., Kippington Park; F. F. Back, Esq., Woodlands; J. C. Forster, Esq., Clatford Mills; C. Gill, Esq., Java Lodge; Lieutenant Munro, Rhinefield; H. De La Rue, Esq., The Lodge; Sir E. J. Loder, Bart., Leonardslee; Morgan and Kidd, Kewfoot-road; Cousins, Thomas, and Co., Oxford; Union Discount Co., Cornhill; Metallurgical Laboratory, King's College; Hornsby and Sons, Grantham; A. S. Bolton, Esq., Moor Court; A. Wilson, Esq., 17, Grosvenor-place; and the completion of the lighting of Alnwick Castle for His Grace the Duke of Northumberland. A large number of wiring contracts have also been completed for Sir Augustus Adderley, Lord Reay, Lady Metcalf, etc. The sale of the Cardew instruments, the patents for which are held by the firm, has considerably increased, and the use of the voltmeter has become more general. The earthing device has been accepted by the London Electric Supply Company, the Newcastle Company, and the Metropolitan Supply Company, and arrangements are made for driving the printing machinery at New Scotland Yard by means of electricity.

Electrical Accessories Company.—This company has been engaged in the arduous task of establishing a reputation, and completing its standard patterns of switches, fuses, etc., in which it is already doing a brisk trade. The orders received have considerably exceeded the manufacturing output of the works, and it is intended shortly to issue fresh capital and move into larger premises.

J. H. Holmes and Co., of Newcastle-on-Tyne, have been kept extremely busy throughout the year, their output in dynamos being about double that of any previous year. They have sold during that period 152 dynamos having an average output at usual speeds of 18,000 watts each, or equal to maintaining say 45,000 glow lamps of 16 c.p. The demand for these machines has increased so rapidly that, although the works have doubled in size during the year, the firm have been obliged to decline some urgent orders. Messrs. J. H. Holmes and Co. have, in addition to supplying other electrical engineers with dynamos, completed 66 installations of electric light in mills, factories, residences, steamships, etc.

Johnson and Phillips.—A large number of both continuous-current and alternating dynamos have been built and sold. Amongst the former were machines for the Duke of Northumberland, K.T.; the General Post Office, Birmingham; the National Museum and Libraries, Dublin (coupled direct to Willans engines); Madame Tussaud's exhibition; and many others, for important installations and for ship lighting. Amongst the latter may be mentioned complete sets for the Hong Kong central station, a machine for the extension of the Keswick central station, and several others for the Continent. Eleven sets of the Kapp central station continuous-current dynamos are now being built for the Vestry of St. Pancras, the first local authority in London that will undertake the supply of electricity themselves. The battery department has been fully occupied in making complete sets of accumulators. The vulcanised rubber shops have also been full of work, making cables for the electric light and transmission of power. The business in the Brockie-Pell arc lamp department has been extremely satisfactory, and shows a very large increase over 1889. Amongst the numerous establishments where this lamp has been introduced during the year may be mentioned the following: General Post Office, London; General Post Office, Birmingham; the Royal Mint, London; the Government Quays, Sydney, N.S.W.; the National Museum and Libraries, Dublin; "The Empire," and many other theatres; Madame Tussaud's exhibition; the Gaiety Restaurant; Spiers and Pond's new stores, Water-lane, E.C.; Winchester House, Old Broad-street, E.C.; Sir Arthur Guiness, Son, and Co., Limited, Dublin, etc. A large number of these lamps have also been supplied for the lighting of railway stations belonging to the Great Northern, Great Eastern, Lancashire and Yorkshire, and other companies, whilst a few alternating lamps have been placed in the streets of Newcastle-on-Tyne for public lighting. The arrangements are now on the point of completion for lighting all the principal streets and quays in Hong Kong with double-carbon 32-hour lamps on the continuous-current series system. Several additional buildings have been erected by this firm during the year to meet the general growth of the business.

Laurence, Scott, and Co.—During the past year the business of this company has made considerable strides, and for some months past all the different departments have been overfull of work, necessitating a great deal of overtime to complete the numerous orders in the factory without disappointment to the various customers. The company is now well supplied with orders for dynamos and motors, etc., from different parts of the United Kingdom and abroad. Among others nearing completion is a large dynamo to generate 2,500 amperes to be used in the reduction of aluminium, also a 40-unit continuous-current transformer, just completed for the Chelsea Electricity Supply Company, and a large 600-lighter dynamo for Messrs. J. and J. Colman, of Norwich. The company has, within the last few months, introduced a specially wound accumulator dynamo, that will charge cells and supply constant E.M.F. to lamp mains independently and at the same time. The company have already manufactured and supplied two or three of these machines, and they are working with complete satisfaction. A great demand for these is anticipated, as their advantages are so apparent. The company holds a patent for a system of underground mains, but as yet has not had an opportunity of laying any length. They hope, however, during the coming year to put them in use in both Norwich and Ipswich, when provisional orders are granted. During the year they have made lengthy and exhaustive experiments with their patent electricity meter, and have now brought it to such a point that very shortly it will be ready for the market. They say that its range is very wide and accurate, and also that the cost will enable it to be made at a very low price. The installation department has also been kept fully employed, and can point to several installations in all parts of the country, including business premises, mills, flour mills, breweries, country houses, and private residences and hotels, as well as work emanating from the development of the central supply stations at Norwich and Ipswich, where there is an increased use of electric motors, which shows a growing appreciation of their usefulness. Scott's patent instantaneous fuses have been introduced to a large extent in installation work, and give great satisfaction both to customers and fire insurance companies.

Paterson and Cooper.—During the whole of the year Messrs. Paterson and Cooper have been busy, and have carried out a large number of shiplighting installations. Amongst the vessels lighted have been the "Peruvian," "Brazilian," and "Parisian," belonging to the Allan Line; the "City of Vienna," "City of Venice," "City of Perth," and "City of Dundee," for the City Line; and the "Arranmore" and "Tuskar," for the Clyde Shipping Company. They have now in hand the lighting of the "St. Nicholas" and "St. Sunniva," the "America" and four new boats for the Manchester, Sheffield, and Lincolnshire Railway. By far the greater part of Messrs. Paterson and Cooper's manufactures are purchased by contractors who erect plant themselves, or by shippers who forward them to distant parts. In all manufacturing departments the business has been brisk. A larger number of dynamos has been turned out than in any previous year, and the sizes have all round averaged larger. Especially noticeable is the increased demand for direct-driven combinations, Chandler, Westinghouse, Tower, and other special types of engines being freely employed for coupling to the dynamos, in addition to those of the 'inary inverted open-fronted class. In the instrument and fittings department trade has also been good, a new alternating-current arc lamp having been designed which gives great satisfaction in working. Amongst the installations which Messrs. Paterson and Cooper have carried out themselves during the year are the lighting of Messrs. Symington's Stay Factory at Market Harborough, and the depot of the Tank Storage Company at Purfleet. They have also completely fitted an installation at Balnagowan Castle, Ross-shire, the residence of Sir Charles Ross, Bart.; Arthurs Club and The White Hart Hotel at Windsor have been fitted throughout, the current being furnished by supply companies. They have in hand the lighting of Messrs. Lipton's shops in London, Dublin, and Birmingham, and are at the moment at work on an installation of arc and incandescent lamps at works of the Lancaster Wagon Company. The prospects for the new year are very encouraging.

Swinburne and Co.—This firm only got into their new premises in May, and since then have had to fit up all the necessary machinery and apparatus for making transformers. In spite of this they have supplied several to various power stations in England, and also taken orders for abroad. The firm sees a good prospect of developing large businesses in France, Germany, Austria, and Italy, as well as in the United States, and are executing several foreign orders. Though business, as might be expected, does not seem to be so brisk just at the close of the year as it was a few months ago, still the works are considerably behind with the orders.

Ransomes, Sims, and Jefferies.—During the past year Messrs. Ransomes, Sims, and Jefferies, of Ipswich, who have always been well to the fore in the adaptation of their engines for electric light purposes, have, we are glad to find, considerably extended their connections in this department. They have supplied and erected a very fine 30-h.p. compound stationary engine, fitted with patent automatic expansion gear, at Fareham, in Hampshire, one of the small towns in which the electric light has been adopted, it being the third town in England wholly lighted by electricity. The lighting is undertaken by the Fareham Electric Light Company, who have an overhead installation throughout. The wires are carried on tall poles, to comply with the Board of Trade regulations, and as the principal street is a long straight one, this method of wiring does not present any great difficulty. The two chief streets, with a united length of about a mile, are lighted with 21 arc lights on the Thomson-Houston system. Each lamp is calculated to give a light of 1,200 candles, but owing to the use of opal globes to disperse the light, probably each lamp does not give an actual light of more than 900 candles. The result is, however, eminently satisfactory, as the streets in question are so light that good print can be easily read at any part of them. The other streets of the town are lit by incandescent lamps of 20 c.p. each, and by arrangement with the Local Board are placed at every point where a gas lamp was situated. As the gas lamps only gave a light of 15 c.p., there is a slight gain of light at each lamp. There are thus two systems, necessitating two separate sets of wire, one for each kind of lamp. For the public lighting about 12 miles of wire are used. It is insulated with okonite. Another set of wires will shortly be run for the purpose of private lighting. The central station, where the motive power and the dynamos are situated, is a long building, built of brick, and the end of it, which contains the dynamos, is matchboarded in order to keep out damp. It is furnished at present with a boiler, an engine, and two dynamos, one for the arc lights and one for the incandescent. At the recent Edinburgh Exhibition one of Messrs. Ransomes 10-h.p. long-stroke engines was employed for driving the exhibits of Messrs. Norman and Son, Limited, giving, we understand, the most unqualified satisfaction. In addition to these and other engines for England Messrs. Ransomes have sent some of their engines this year for electric light installations in India, so that there is hardly any part of the world in which Messrs. Ransomes' engines are not found driving electric light machinery of various systems.

THE SCHOOL OF ELECTRICAL ENGINEERING have during the past year considerably increased their apparatus, more particularly in the dynamo department, other dynamos having been added, making five in all, of various types, and the present gas engine, which has been too small for their requirements, will be replaced by an 8-h.p. gas engine. This is in addition to their present steam engine, making altogether a very comprehensive model installation. The teaching has been considerably modified to keep up with the requirements of the time, and a great deal more attention has been paid to mechanical engineering. The number of students during the past year has been about 40. Examinations of a practical nature have been carried out by Mr. Gisbert Kapp for the electrical engineering, and Mr. H. R. Kempe, of the General Post Office, in the telegraphic and telephonic classes. The school has recently suffered a great loss in the sad death of Dr. Lant Carpenter, one of its joint managers, but during his illness for the last eight or nine months his co-manager, Mr. Leon Drugman, M.I.E.E., has carried on the work alone, and the school will continue as before. The professors and teachers are Mr. Chas. Capito, M.I.C.E., M.I.E.E., Mr. E. C. Rimington, A.I.E.E. (who has been away on account of health, but resumes his duties in April), Mr. E. T. Carter, A.I.E.E., Mr. E. Wythe Smith, A.I.E.E. Mr. Drugman, besides acting secretary, also takes the course in telegraphy.

THE ELECTROMAGNET.*

BY PROF. SILVANUS P. THOMPSON, D.SC., B.A., M.I.E.E

LECTURE IV.

(Continued from page 575, Vol. VI.)

You may remember that I produced an apparatus, Fig. 27, which I said was the only apparatus hitherto devised which did directly prove experimentally the law of inverse squares for the case of a magnetic pole. There was in it a pole, virtually a point at a considerable distance from a small magnetic needle, which was also virtually a point.

The law of inverse squares is true; but it is not what one works with when one deals with electromagnets having ends of a visible size, acting on armatures themselves of visible sizes, and quite close to them. If you take a case which never occurs in practice, an armature of hard steel, permanently magnetised, so far away from an electromagnet (or, rather, from one pole only) that the distance between the one pole and the armature on which you are acting is so very great compared with each of them, that each of them may be regarded by comparison as a point, then the law of inverse squares may be rightly applied, but not unless.

Now we want to arrive at a true law. We want to know exactly what the law of action of the coil and plunger is. It is not a very difficult thing to work out, provided you get hold of the right ideas. We must begin with a simple case, that of a short coil consisting of but one turn, acting on a single point-pole. From this we may proceed to consider the effect on a point-pole of a long tube of coil. Then we may go on to a more complex case of the tube coil acting on a very long iron core; and, last of all, from the very long iron core we may pass to the case of a short core.

You all know how a long tube of coil such as this will act on an iron core. Let us make an experiment with it. I turn on the current so that it circulates around the coil along the tube, and when I hold in front of the aperture of the tube this rod of soft iron it is sucked into the coil. When I pull it out a little way it runs back, as with a spring. The current happens to be a strong one—about 25 amperes; there are about 700 turns of wire on the coil. The rod is about 1in. in diameter and 20in. long. So great is the pull that I cannot pull it entirely out. The pull was very small when the rod was outside, but as soon as it gets in it is pulled actively, runs in, and settles down with the ends equally protruding. The tubular coil I have been using is about 14in. long; but now let us consider a shorter coil. Here is one here only half an inch from one end to the other, but I have one somewhere still shorter, so short that the length, parallel to the axis, is very small compared with the diameter of the aperture within. The wire on it consists of but one single turn. Taking such a coil, treating it as only one single ring, with the current going once round, in what way does it act on a magnet that is placed on the axis? First of all, take the case of a very long, permanently magnetised steel magnet, so long, indeed, that any action on the more distant pole is so feeble that it may be disregarded altogether, and only one pole, say the north pole, is near the coil. In what way will that single turn of coil act on that single pole? This is the rule, that the pull does not vary inversely as the square of the distance, nor as any power at all of the distance measured straight along the axis, but inversely as the cube of the slant distance. Let the point O in Fig. 58 represent the centre of the ring, its radius being y. The line O P is the axis of the ring, and the distance from O to P we will call x. The slant distance from P to the ring we will call a.

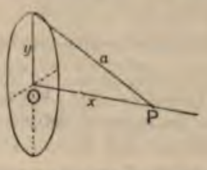

FIG. 58.—Action of Single Coil on Point-pole on Axis.

Then the pull on the axis towards the centre of this coil varies inversely as the cube of a. That law can be plotted out in a curve for the sake of observing the variations of pull at various points along the axis. Allow me to draw your attention to Fig. 59, which represents a section or edge view of the coil. At various distances right and left of the coil are plotted out vertically the corresponding force, the calculations being made for a current of 10 amperes, circulating once round a ring of one centimetre radius. The force with which such a current acts on a magnetic pole of unit strength placed at the central point is 6·28 dynes. If the pole is moved away down the axis, the pull is diminished; at a distance away equal in length to the radius it has fallen to 2·22 dynes. At a distance equal to twice the radius, or one diameter, it is only 0·56 dynes, less than one-tenth, of what it was at the centre. At two diameters it has fallen to 0·17 dyne, or less than 3 per cent.; and the force at three diameters is only about 2 per cent. of that at the centre.

If, then, we could take a very long magnet, we may utterly neglect the action on the distant pole. If I had a long steel magnet with the south pole 5ft. or 6ft. away, and the north pole at a point three diameters—*i.e.*, 6 centimetres in this case—distant from the mouth of the coil, then the pull of the current in one spiral on the north pole, three diameters away, would be practically negligible; it would be less than 2 per cent. of what the pull would be of that single coil when the pole was pushed right up into it. But now, in the case of the tubular coil, consisting of at least a whole layer of turns of wire, the action of all the turns has to be considered. If the nearest of the turns of wire is at a distance equal to three diameters, all the other turns of wire will be at greater distances, and, therefore, if we may neglect such small quantities as 2 per cent. of the whole amount, we may neglect their action also, for it will be still smaller in amount. Now, for the purpose of arriving at the action of a whole tube of coil, I will adopt a method of plotting devised by Mr. Sayers. Suppose we had a whole tube coiled with copper wire from end to end, its action would be practically the same as though the copper wire were gathered together in small numbers at distant intervals. If, for example, I count the number of turns in a centimetre length of the actual tubular coil which I used in my first experiment, I find there are four. Now, if instead of having four wires distributed over the centimetre I had one stout wire in the middle of that space to carry four times the current, the general effect would be the same. This diagram, Fig. 60, is calculated out on the supposition that the effect will not be greatly different if the wires were aggregated in that way, and it is easier to calculate. If, beginning at the end of the tube marked A, we take the wires over the first centimetre of length and aggregate them, we can draw a curve, marked 1, for the effect of that lot of wires. For the next lot we could draw a similar curve, but instead of drawing it on the horizontal line we will add the several heights of the second curve on to those of the first, and that gives the curve marked 2; for the third part, add the ordinates of another similar curve, and so gradually build up a final curve for the total action of this tubular coil on a unit pole at different points along the axis. This resultant curve begins about 2½ diameters away from the end, rises gently, and then suddenly, and then turns over and becomes nearly flat with a long level back. It does not rise any more after a point about 2½ diameters along from A; the curve at that point becomes practically flat, or does not vary more than about 1 per cent., however long the tube may be. For example, in a tubular coil 1in. in diameter and 20in. long, there will be a uniform magnetic field for about 15in. along the middle of the coil. In a tubular coil 3 centimetres in diameter and 40 centimetres long, there will be a uniform magnetic field for about 32 centimetres along the middle of the coil. The meaning of this is that the value of the magnetic forces down the axis of that coil begins outside the mouth of the tube, increases, rises to a certain maximum amount a little within the mouth of the tube, and after that is perfectly constant nearly all the way along the tube, and then falls off symmetrically as you get to the other end. The ordinates drawn to the curve represent the forces at corresponding points along the axis of the tube, and may be taken to represent not simply the magnetising force, but the pull on a magnetic pole at the end of an indefinitely long, thin steel magnet of fixed strength.

* Cantor lectures, delivered before the Society of Arts.

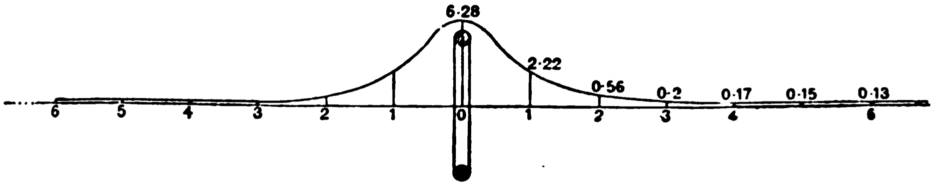

FIG. 59.—Action along Axis of Single Coil.

The rule for calculating the intensity of the magnetic force at any point on the axis of the long tubular coil within this region where the force is uniform is:

$$H = \frac{4}{10}\pi \times \text{the ampere-turns per cm. of length.}$$

And, as the total magnetising power of a tubular coil is proportional not only to the intensity of the magnetic force at any point, but also to the length, the integral magnetising effect on a piece of iron that is inserted into the coil may be taken as practically equal to $\frac{4}{10}\pi \times$ the total number of ampere-turns in that portion of the tubular coil which surrounds the iron. If the iron protrudes as much as three diameters at both ends, the total magnetising force is simply $\frac{4}{10}\pi \times$ the whole number of ampere-turns.

Now that case is of course not the one we are usually dealing with. We cannot procure steel magnets with unalterable poles of fixed strength. Even the hardest steel magnet, magnetised so as to give us a permanent pole near or at the end of it—quite close up to the end of it when you put it into a magnetising coil—becomes by that fact further magnetised. Its pole becomes strengthened as it is drawn in, so that the case of an unalterable pole is not one which can actually be realised. One does not usually work with steel; one works with soft-iron plungers which are not magnetised at all when at a distance away, but become magnetised in the act of being placed at the mouth of the coil, and which become more highly magnetised the further they go in. They tend, indeed, to settle down, with the ends protruding equally, for that is the position where they most nearly complete the magnetic circuit; where, therefore, they are most completely and highly magnetised. Accordingly, we have this fact to deal with, that whatever may be the magnetising forces all along a tube, the magnetism of the entering core will increase as it goes on. We must therefore have recourse to the following procedure. We will construct a curve in which we will plot not simply the magnetising forces of the spiral at different points, but the product of the magnetising forces into the magnetism of the core which itself increases as the core moves in. The curve with a flat top to it corresponds to an ideal case of a single pole of constant strength. We wish to pass from this to a curve which shall represent a real case, with an iron core. Let us still suppose that we are using a very long core, one so long that when the front pole has entered the coil the other end is still a long way off. With an iron core of course it depends on the size and quality of the iron as to how much magnetism you get for a given amount of magnetising power. When the core has entered up to a certain point, you have all the magnetising forces up to that point acting on it; it acquires a certain amount of magnetism, so that the pull will necessarily go on increasing, and increasing although the intensity of the magnetic force from point to point ng the axis of the coil remains the same, until within about two meters from the far end. Although the magnetic force inside long spiral remains the same, because the magnetism of the e is increasing, the pull goes on increasing and increasing (if the n does not get saturated) at an almost uniform rate all the way the piece of iron has been poked pretty nearly through to end. In Fig. 61, a tubular coil, B A, is represented.

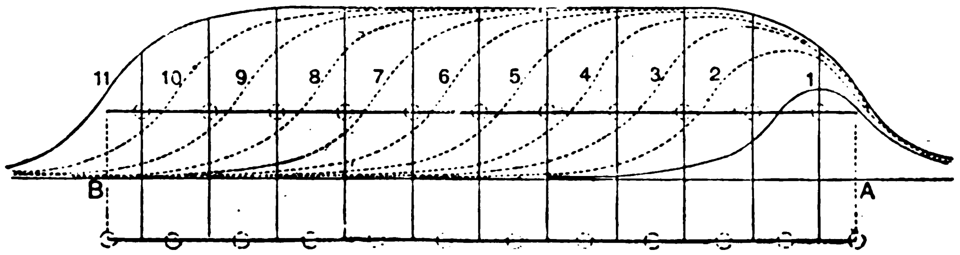

FIG. 60.—Action of Tubular Coil.

Suppose a long iron core is placed on the axis to the right, and that its end is gradually brought up toward B. When it arrives at X the pull becomes sensible, and increases at first rapidly, as the core enters the mouth of the tube, then gently, as the core travels along, attaining a maximum, C, about at the further end, A, of the tube. When it approaches to the other end, A, it comes to the region where the magnetising force falls off, but the magnetism is still going on increasing, because something is still being added to total magnetising power, and these two effects nearly balance one another, so that the pull arrives at the maximum. This is the highest point, C, on the curve; the greatest pull occurring just as the end of the iron core arrives at the bottom or far end of the tubular coil; from which point there is a very rapid falling off. The question of rapidity of descent from that point depends only on how long the core is. If the core is a very long one, so that its other pole is still very far away, you have a long, slow descent going on over some three diameters, and gradually vanishing. If, however, the other pole is coming up within measurable distance of B, then the curve will come down more rapidly to a definite point, X_1. To take a simple case where the iron core is twice as long as the coil, its curve will descend in pretty nearly a straight line down to a point such that the ends of the iron rod stand out equally from the ends of the tube.

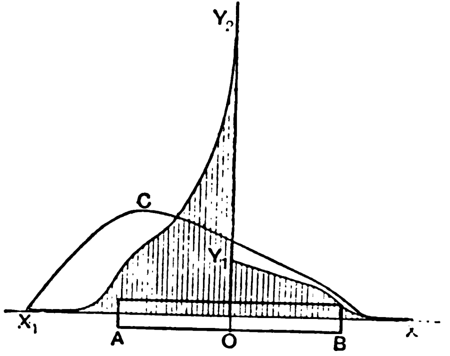

FIG. 61.—Diagram of Force and Work of Coil and Plunger.

Precisely similar effects will occur in all other cases where the plunger is considerably longer than (at least twice as long as) the coil surrounding it. If you take a different case, however, you will get another effect. Take the case of a plunger of the same length as the coil, then this is what necessarily happens. At first the effects are much the same, but as soon as the core has entered about half, or a little more than half its length, you begin to have the action of the other pole that is left protruding outside tending to pull the plunger back, and although the magnetising force goes on increasing the further the plunger enters, the repulsion exerted by the coil on the other pole of the plunger keeps increasing still faster as this end nears the mouth of the coil. In that case the maximum will occur at a point a little further than half way along the coil, and from that point the curve will descend and go to zero at A; that is to say, there will be no pull when both ends of the plunger coincide with the two ends of the coil. If you take a plunger that is a little shorter than the coil, then you find that the attraction comes down to zero at an earlier period still. The maximum pull occurs earlier, and so does the reduction of the pull to zero, there being no action at all upon the short core when it lies wholly within that region of the tube within which the intensity of the magnetic force is uniform. That is to say, for any portion of this tube corresponding to the flat top of the curve of Fig. 60 if the plunger of iron is so short as to lie wholly within that region, then there is no action upon it. It is not pulled either way.

(To be continued.)

CORRESPONDENCE.

GRAVESEND LIGHTING.

To the Editor of the Electrical Engineer.

Sir,—As desired by you in your leading article of the 26th Dec., I write to say that the statement concerning the Gravesend lighting therein referred to is, so far as this company is concerned, absolutely without foundation.

It is, I believe, well known that this company has long since discontinued installation work, and it has nothing whatever to do either directly or indirectly with the promotion or carrying out electric lighting works.

We do not know how the "error" or misstatement has arisen—we have had no communication with anyone concerning an electric light station at Gravesend.

I beg, therefore, to give the statement a "direct and unmistakable denial."—Yours, etc.,

S. Flood Page, Secretary and Manager.
Edison and Swan United Electric Light Company,
Limited, 31st December, 1890.

SECRET SOLUTIONS.

To the Editor of the Electrical Engineer.

Sir,—In reference to your short leader in your issue of the 19th Dec., will you kindly allow me to say that, as honorary secretary and member of council of this institute, my only interest in any invention brought before our members at our evening meetings is that it is one *worthy* of notice. I have had a pretty wide experience, extending over many years, of primary batteries, and I am by no means sweet on them, as the saying goes. Some four years ago I was taken to see Mr. Gauzentes' battery and it impressed me favourably. Since then he has plodded away at his electrical inventions in an earnest practical manner, and when he recently showed me the results of his labours I advised one of our evening meetings being devoted to the subject.

Before asking Mr. Spagnoletti to take the chair a miner's lamp duly charged was handed by Mr. Gauzentes to him, and left with him at his own house for trial and test. This lamp lasted out the time stated, and by further immersion of the zincs endured for 20 hours. Mr. Spagnoletti would have presided at the meeting, but at the last moment he was telegraphed to the City and South London Electric Railway, to which he is the consulting engineer, for a conference with the chairman of that company previous to the opening of the railway for public traffic on the following day.

The sole reason of Mr. Gauzentes' secresy is his immediate inability to secure the foreign patents necessary for the protection of his inventions.—Yours, etc.,

S. T. Mackie, Honorary Secretary.
Inventors' Institute, 27, Chancery-lane, W.C.,
27th December, 1890.

COMPANIES OF 1890.

The following are the principal new electrical companies that have been registered during the past year :

Name of Company.	Capital Authorised.	Capital Offered.	Amount of Shares.	Deposit.	Total. Deposit
	£	£	£	£	£
Column Printing Telegraph	100,000	50,000	1 0 0	0 15 0	37,500
Devon and Cornwall Electricity Supply	100,000	75,000	5 0 0	1 0 0	15,000
Electrical Engineering Corporation	170,000	77,000 20,000	5 0 0 Debs.	1 10 0 30 p. c.	29,100
Electric and General Investment	200,000	190,000	5 0 0	1 0 0	20,000
Elmore's Austro-Hungarian Patent Copper Depositing	200,000	200,000	2 0 0	1 0 0	100,000
Elmore's French Patent Copper Depositing	200,000	200,000	2 0 0	0 15 0	75,000
Elmore's Wire Manufacturing	300,000	200,000	2 0 0	1 10 0	150,000

UNDERGROUND ELECTRIC WORK.

BY DAVID BROOKS.

While looking over the proceedings of the Chicago Electric Club, as printed in your paper, I was preparing myself to walk into that concern and make a disturbance, when I found Herbert Laws Webb had forestalled me, and taken a portion of the wind out of my sails. Still there is a good deal that is left undone. Mr. Degenhardt states: "The insulation resistance should not be less than 500 megohms per mile, and the insulation should not materially deteriorate for the space of two years after being in service on an electric light circuit, having a voltage of from 2,500 to 3,000 volts, and a current of from nine to 12 amperes, or a voltage of from 900 to 1,200 volts, and a current of from 18 to 20 amperes." A galvanometrical test of this nature for an electric light conductor I consider of no earthly use, but agree with Wm. Maver, jun., in an article published in the *Western Electrician* of March 1st, 8th, and 15th of the present year, that a cable measuring 20,000 megohms per mile for insulation in the factory, was broken down by a dynamo current of 600 volts after being drawn into a conduit. In speaking of all these tests, Mr. Degenhardt makes no reference to temperature, although in a Chicago atmosphere the insulation resistance is certainly 10 times as high at the temperature of freezing as at the temperature of 80.

As Mr. Webb states, the cable should be immersed in water, but even that is not satisfactory if the cables are to be used for electric lighting purposes. The method employed by Johnson and Phillips, of London, is spoken of as follows, in a letter under date of November 4th last, referring to a line laid at Charlton: "We have at last had Ferranti, Dr. Fleming, Gordon, and others down to see it. Yesterday we had a current of about 14,000 volts on this line for about five hours, and it stood it perfectly; we took the current from a 2,000-volt Kapp alternator and transformed up to 14,000 volts to the line. At the distant end we had another transformer and converted it to 2,000 volts again, and lighted 20 100-volt 16-c.p. lamps in series, and I am writing to Ferranti and others to come and see the test repeated."

Cables that may test enormously high with a galvanometer often break down and disrupt with currents of high voltage, and especially is this the case with lead-encased cables; the coiling and uncoiling of this class opens spaces in the insulation which are nothing more than vacuum tubes or Geisler tubes. Varley made use of these years ago to protect ocean cables from atmospheric electricity. Last winter I laid an electric light cable in Gloucester, a No. 0 conductor; the insulation resistance of that cable at 32deg. F. is 1,000 megohms per mile; but in August last, when the temperature of water from the hydrant was at 81, the insulation dropped to three megohms per mile. This cable stood the current of a 2,000-volt alternating current, but, as an experiment, we heated a portion of the cable up to 150deg. F., and brought the insulation down to 5,000 ohms per mile, and tried to break or disrupt the insulation without any effect whatever. It was then tested with a Holtz machine, which produced a spark 6in. in length, to ascertain whether the insulation could be punctured, but without effect. Five thousand ohms per mile does not sound very high, but if the conductor was a No. 3 instead of a No. 0, only one part of the current would go to the earth, while 5,000 parts would keep to the wire.

Currents of great intensity centre upon weak spots and develop them into perfect grounds. Culley speaks of this fact, and it is for that reason chiefly that the Atlantic cables are worked with only two cells, and nothing can be more absurd than the statement, "Electrical currents of infinitesimal potential are no more easily conducted than are those electrical giants of four or five thousand volts." It has especial bearing upon lead-covered cables with inside textile covering. Coiling and uncoiling is liable to open pores, admitting moisture, especially so when laid under water.

Mr. Sunny says: "In arc light service if we get one megohm to the mile we are perfectly contented." Mr. Sunny, speaking of telephone cables, says: "The company also put down what was known as the Brooks cable in a 3in. iron pipe filled with resinous oil. It extended from the business part of the city to Twenty-second-street, and never gave satisfaction from the outset. I believe it is still working in some sections, but not in a satisfactory manner." In this connection I quote from Prof. Barrett: "Now, then, the question of insulation is another thing. You can get all the insulation you want and a good deal more. I recollect a short time ago that a cable was abandoned here because the insulation was so high that they could not use it. Gentlemen in the room know that to be a fact. They had to reduce the insulation so that the cable would work." A few days ago I was in Chicago, and Prof. Barrett said the words just quoted had reference to the Brooks cable in that city laid four years since. When the cable was first laid, Mr. Sunny wrote that it was a perfect success; in the next letter he stated there was a great deal of retardation on the Brooks cable when an overhead cable was connected into it at Twenty-second-street, and when it was still lengthened by connecting in another cable at La Salle-street, the Brooks cable as a trunk line was nearly worthless; but taking the "poorest insulated wire," they could use it fairly well.

I got Geo. H. Bliss to try the cable himself, and he wrote as follows: "Scarcely any cross-talk or induction sounds could be heard by me on Brooks cable wires in any of these tests. Pronunciation of difficult names was tried on all the Brooks wires with success, except in those cases especially difficult for telephone transmission. This afternoon I went, at Mr. Brooks's request, to the Chicago Avenue exchange, where conversation was carried on through a wire in a Patterson cable to the La Salle-street exchange, about one mile distant. The cross-talk and induction were much more pronounced than on the Brooks cable wires used in the morning, although the distance was only one-third as great."

History has record of the better working of ocean cables by putting in leaks. Culley speaks of it in the cables that are laid from island to island in the Mediterranean. Sabins, in his work published in 1867, states that Kramer improved the insulation of the underground wires in Germany by reducing the insulation, so there is nothing wonderful in the statement of Mr. Sunny that the poorest insulated worked the best. The great fault with the cable is that the conductors were too large, No. 16; if they had been No. 22 the inductive disturbance would not have been more than half as great. I protested against the use of such heavy conductors, there being 510 in a 3in. pipe. What is needed in telephone service is not so much volume as distinctness of articulation. Since then I laid a cable of 53 conductors for the Pennsylvania Railroad Company, of Philadelphia, and one of them was a very small wire, No. 22, laid for the purpose of a test wire. This cable is used for both telephonic and telegraphic purposes, and it has been found that the small wire serves much better than any of the others for telephone uses, for the reason that it occupies no more than half the space in the inductive field. Using the No. 16 wire you do not reduce the resistance of the circuit, which includes telephones and transmitters, 1 per cent., but you increase the inductive disturbance 50 per cent.

As an experiment we connected in as many as 10 of the No. 16 wires, using them in parallel, and thereby reducing the resistance to merely nothing, or next to nothing, and then listened to the noise. We were enabled to hear the hum of the electric light dynamos. The amount of this is to show that there has been a great deal of copper wasted in telephone cables of short length, but in long distance telephoning, where the circuit is double in length to make it metallic, then conductivity becomes essential.

Mr. Sunny, referring to electric light cables, makes the following statement: "In the electric lighting business I claim that the underground work is not a complete success for the reason that the lights are apt to go out once a week from some underground defect. The insulation is liable to run down so low on short notice as to require the shutting down the circuit for repairs." Now, with the Brooks's system, patented in 1887, an entirely different state of affairs exists. With nine installations working, most of them upward of a year, not a single interruption has occurred. Prof. Barrett states: "It is a fact with the underground system of Chicago to-day that you deliver more of your product at the lamp than you did with the overhead system." At Gloucester we used Johnson and Phillips's method of insulating the lamps, and with 22 terminals exposed to the rain, we got a much higher insulation than on a clear day at the same temperature, because some of the pipes and lampposts are exposed to the rays of the sun. An ordinary glass insulator exposed to the smoke and soot will not show in Chicago, in the rain, an insulation of over a megohm, and there is a great deal in this particular point of carrying the full current to the lamps as pointed out by Prof. Barrett. There is much said about subways and conduits. I consider the best of them an unmitigated nuisance, and of no earthly use. Nineteen No. 4 electric light conductors can be drawn into a 2in. diameter pipe, the conductors not costing over five cents a foot. Think of what Mr. Laws says, a good electric light conductor can be had for 1,250dol. per mile, and that Mr. Degenhardt says the rental of a duct is 1,000dol. a mile per annum. If electric light companies must pay these figures they should never be obliged to go underground. Mr. Kemp says: "I think in this discussion a comparison of the cost ought to be mentioned for good reasons. So if any gentleman is prepared to give us some figures, showing the difference in cost between aerial and underground construction, I should like to hear them." I should very much like to go into figures, but it is impossible to do so unless one knows what is wanted. If a person should ask me how much it costs to build houses, I should state that it depends very much on the kind of a house you want, and if anyone will specify what is required I will at once estimate for the work, and promise that it does not cost one sixth of any other underground system, and but little or if any more than an overhead system.

Two years since a wood conduit was laid on Chestnut-street, Philadelphia, and the street being narrow, the traffic was incommoded by immense heaps of earth that were thrown out. Some electric light wires have been drawn into them, and the conduit has taken fire twice between Seventh and Eighth streets, destroying all the conductors, and a portion of the conduit had to be rebuilt. There have been several other fires that have come under my notice, one at Fourth and Chestnut, and another at Eleventh and Chestnut. There the conduit had to be rebuilt for half a square. Not more than a couple of weeks since an explosion occurred at Ninth and Chestnut streets, breaking every window upon one side of a street car.

There are four conduits in Chestnut-street. In this same locality, but on the south side of the street, a manhole blew up, and sent up the cover through the window, which consisted of a large French plate glass, into the store of Porter and Coates. Between pumping water out and fanning fresh air into these conduits, there is quite a new industry established.

The idea that you can pull in and pull out in making repairs is popular, and that you have spare ducts to put in more conductors when needed, is also popular; but in practice here the first thing necessary after you pull in a cable, is to pull it out again and repair damages. Rubber and guttapercha are soon destroyed when exposed to the atmosphere of a wood conduit. Lead is turned into white lead. Prof. Marks calls wood conduits white lead factories. To preserve the white lead they cover it with a braid saturated with black paint. When drawn into the conduit the paint is as dry as any other paint after it is exposed to the air, and does not adhere to the hand, but after it has been in the conduit a week, this paint becomes liquid, thinned, and leaves a black mark on your hand if you touch it. Illuminating gas is only another form of hydrocarbon or fatty matter, and acts as a solvent, like benzine upon grease spots. The paint and braid preserve the lead for a while, but are not lasting. About a month since they undertook to draw in some electric light conductors in this wood conduit at Broad and Chestnut-streets, and after punching with their iron rods to get a passage for pulling in rope, they found the conduit was rotten, and the whole thing for 60ft. or more across Broad-street, the widest street in Philadelphia, had to be dug up and a new conduit laid. Broad-street at this place is paved with asphalte, and the gang of men were making repairs there for about 10 days. Broad-street is Fourteenth-street if numbered. When they got as far as Fifteenth-street they had another circus of the same nature and had to put in a new duct. It seems to me that anybody that would spend money for a conduit at this time must be demented, yet another company is now laying in this same Broad-street a wood conduit. I consider this a case of aggravated dementation: "If the blind lead the blind, both fall into the ditch," which is the scripture name for conduit. I must quote a scrap from an author of the twelfth century, Mr. Dante: "These may be called flocks of sheep, and not men; for if one sheep should throw himself down a precipice of a 1,000ft. all the rest would follow; and if one for any cause in passing a road should leap, all the rest would do the same, though they saw nothing to leap over."

EDISON AND THE INTERVIEWER.

[We reproduce below an interesting account of an interview with Edison.—Ed. *E.E.*]

Thomas Alva Edison should be a very happy man. Since the days when he was a telegrapher in Boston fortune has smiled upon him every hour in the twenty-four. It is not too much to say, perhaps, that he is the best known American.

His wonderful ingenuity or genius has made his name a household word the world over, and yet he is only forty-three years of age. During his lifetime he has taken out over 400 patents on his own inventions. From the hour when the incandescent light became a practical illumination his fortune has gone on piling up in such proportions that he may safely be estimated to be worth from three to five millions of dollars. He is one of the few men of inventive genius who has made anything out of his patents.

He is happily married to a daughter of the many times millionaire, Miller, of Akron, Ohio. A charming woman, who will some day add from three to five millions more to her husband's fortune.

Charming Environments.

The visitor to Edison's home and laboratory at Llewellyn Park, on the Orange Mountains, a few miles from Jersey City, is surprised and gratified by the beauty of the scene. The Wizard of the New World occupies a beautiful villa that was built by a man who decamped with a large fortune, and threw the property on the market at a sacrifice. Edison's luck was present at this hour, and he bought the handsome place for a song. Llewellyn Park is one of the most charming spots imaginable. There is no place in it for a poor man. Only the wealthy can inhabit the fine houses that dot the mountain side. There are walks and drives, long paths of green shade trees, and the delicious aroma that comes from innumerable flower beds. A splendid view is obtained from many of these mansions, a view of seven large cities with a population of more than four million souls. A short 10 minutes' walk from Edison's house brings you to his laboratory, perhaps the most complete in the world. You are sure to find the great inventor there at any time you call. He is an early riser, and immediately after breakfast leaves his home for his workshop. Not a workshop in the sense that the word is usually understood, but a great, big, roomy place, finished in hard wood, with fine Smyrna rugs and bear skins on the polished floor, pictures on the walls, and a library of books in a convenient corner There is a reception-room for guests, and adjoining this Edison's sanctum, where he sits hour after hour trying to solve some of the great problems that perplex him.

The Great Inventor.

You would not imagine for a moment that this man is the great inventor. His face is cleanly shaved. His shoulders are broad, and there seems to be a trifle of stoop in them. His large grey eyes are sunken in his head, and his massive Websterian forehead is furrowed with wrinkles. He is quite deaf, and this makes it quite difficult for anyone, particularly an interviewer, to ask him questions, and he is so busy that he has neither time nor patience to talk often for publication. But if you should happen to find him in a pleasant mood, as I did the other morning, you would find him one of the most companionable of men. I asked him a good many leading questions, all of which he answered in a free manner, and without the slightest hesitation. While we were talking he continued at his work. Many of his employés came to consult with him, and at his elbow was one of his numerous secretaries. He always watched the lips of the person talking to him, which assists him greatly in making out what is said. Deaf as he is, it is a little strange that he can hear through the telephone very easily.

The Vital Problem.

"Have you made any important discovery lately ?" I asked him.

"That depends," was his reply, "on what you would call important, I might call important, and the world would call important. I may say that I am at work all the time. I am now engaged on the vital question of electricity—viz., the way to obtain it direct without the aid of other motor power. It has been a study of mine for years, and I confess that I have not succeeded in making the invention. I shall never cease trying to unravel the problem. The man who makes this invention will solve the question of motor power. I would gladly acknowledge the greatness of anyone who could do this, and hail him as the king of inventors. No selfish motives of not being first would keep me from acknowledging his greatness. No other invention would so benefit and revolutionise the world. At present we have to use coal to generate steam, and it in turn gives motor power to the dynamo which produces electricity. Only about 15 or 19 per cent. of the energy of coal is thus used. The result is an expensive and vast waste. Tons of coal are used upon vessels on one trip to Europe, but if electricity can be generated directly from the coal, then only a few basketfuls will be necessary to carry the biggest vessel across the ocean. One pound of coal can carry itself around the globe with its own electrical power. Some kind of a boiler, only made smaller than the present steam boiler, may be the only means necessary to transform coal into electricity, But, of course, the apparatus, its shape, or what it will be, has yet to be invented, as well as the great problem.

Electricity from Coal.

"Have I succeeded in making any headway? Just a little. I can get some electricity direct from coal, but it has no force to speak of. It is not the true force I am looking for. I do not dream over it, but I confess I spend many hours working over it.

"Think of it. Electricity direct from coal? It may sound like an echo of the millennium, but I do not think so. We have succeeded in using electrical force in many and various ways. But electricity can never be the motor of the world if another power is necessary to generate it. The expense is too great, and so the original power is preferable, of course. Now, for a moment imagine the condition of things following this invention : Steam will become a thing of the past, and the greatest and cheapest motor power, electricity, will be universally used. Some idea may be gained of the superior power of the new motors, by stating that it will then only require three days to go to Europe, and only two or three will be consumed in a railroad trip to California. The factory that I run, which now consumes a great quantity of coal daily, will need only a small basketful of coal to keep it going all day. Great factories that annually burn thousands of tons of coal will be run on several tons, say two or three, or a few more per annum, saving many thousands of dollars. The cost of living, the cost of goods, the cost of nearly everything will be reduced. It will cost nothing to make ice. It will be a revolution, not to throw anyone out of employment, not to ruin any industry, but to benefit mankind and civilisation in general."

"Do you ever despair of making the invention or solving the problem ?

Some Use for Men of Science.

"It was reported once that you had invented a process to convert dirt into food ?"

"That was an April fool joke. But great strides are being made in that direction. People have wrong ideas about many of the edibles made artificially, and yet they are just as healthy as the natural product. You, perhaps, have heard that butter is often made out of mud from the bottom of the Thames river. It is not actually from the mud, but from the grease from sewers that gathers in the mud. Why, oleomargarine is good, if not better, and to my idea decidedly more wholesome and purer than butter, if made in an honest way. It is often made by dishonest people, and therefore is impure. No doubt some manufacturers make it better and purer than others, but when bad people, in order to get bigger profits, manufacture cheap oleomargarine it forces others to adopt the same dishonest method. But what is the use of talking about all people being honest. I do not expect the end of the world to come soon, and that would be the case if all people were honest.

Only Cheap Wires Dangerous.

"There is no reason why death should occur from coming in contact with electric wires. Dishonesty, greed, and recklessness are really the causes for all the deaths that occur from electric wires, and there is a remedy. An electric company will deliberately use small, cheap copper wires that carry a strong, deadly current, when for a larger outlay of money large copper wires, which do not carry deadly currents, could be purchased. It is simply a matter of parsimony. For instance, a company will frequently use small copper wires that cost 2,000dols., knowing full well that a deadly current will be in them, rather than pay 8,000dols. or 10,000dols. for large wires that would be harmless. Yet there is a cry against the deadly electric wires. Some of my wires in Lower Broadway are in constant use, and no one has ever been hurt by them. Why? The wires are large, and will last safely until the twenty-fifth century. As long as there are no laws regulating the sizes of electric wires, of course, fatalities may be expected. Steam boilers are inspected, and why electric wires are not is a mystery to me. They could be policed, so to speak, and made as safe as waggons running along the streets."

Gas as Fuel.

"Do you think that lighting by electricity is becoming more popular?"

"Certainly ; because it is getting cheaper every day, and gives a better light than gas. I do not mean to say that gas will be driven out of use, for it will not. It will certainly be done away with as lighting material, and will be used chiefly to heat, nothing more. Already many gas companies have turned their attention towards heating, and succeeded admirably. As a lighting material gas smokes, but used in heating it does not. The smoke from a gas stove usually goes up the chimney, and gas, as a fuel, is much cheaper and cleaner than coal. There are no ashes, no trouble, and none of the annoyances that come with handling coal. This is beginning to be the era of gas heating. Look at the gas used in many towns, where natural gas has been discovered. Why cannot gas be made for heating purposes just as reasonable in price as for lighting? The cost is much smaller than coal or wood heat, and infinitely preferable. Electricity is essentially adapted for lighting purposes, and is superior in many respects. It is becoming cheaper every day. Only 2 per cent. of the coal is turned into light, while nearly all the electric force is turned into light. It is really a saving to use gas for heat, and within the past two years it has become very popular as a heating medium."

About Flying Machines.

"Have you ever thought of inventing a flying machine, the motor force of which would be electricity?"

"Yes, I have given some study to the question, and, of course, made some experiments in that direction. The bumblebee is a fine model to study for a flying machine, and the more I study that species of a high order of birds, the more complex does the flying machine problem appear. The bumblebee flies by the aid of motor power alone. It has no natural aid, but must depend upon the rapid working of its wings to fly. There is no wind and no feathers to assist the bee ; it has small wings, entirely out of proportion to its large, robust body, and when it flies the wings, as any observer can see, are worked so rapidly it is impossible to calculate the number of flops to the minute. But the little bird must, perforce, be the model to solve the flying machine puzzle, because it is propelled simply by native motive power. Could this bumblebee carry the weight of another bee on its back is a question often asked. Well, it cannot; and even if a flying machine were invented on its model it would not be capable of carrying any weight save its own. Nature has done so much, and failed to go any further.

"You see, if wings were applied to a man they would have to be quite small in order to be worked rapidly. Large wings could not be moved rapidly enough, so the question of flying would never be settled by large wings, even if the motive propelling power were a thousand times greater than any yet conceived of. A man might have wings constructed to carry his weight, but that would be all. Like the bumblebee, he would be unable to do anything save carry his own weight, and that by sheer force of great power. Now, seagulls have large wings, entirely out of proportion with their small bodies. But they have little motive power, and are simply kept up like a kite by the wind. If you will notice a gull you will rarely see it work its wings, but it keeps them outstretched and sails around the air in a beautiful style. No flying machine could skim about on the bosom of the wind like the seagull. All birds propel themselves by flying and sailing. It is a natural action, but man cannot acquire it, at least not now in this day and generation, when so many secrets of nature slumber before the *savant's* eyes for years. We can only go back to nature and pause and wait for years to understand the phenomena that now seems a mystery to our very finite minds.

"I am not so sanguine about a flying machine because nature has her limitations. Anyway, many of her secrets lie hidden from us and remain to enrich and glorify some bright and wonderful era in the future. Perhaps a century or so from now the flying principle in man will be invented or discovered. Things unheard and undreamed of may come to light in the future and place us in the category of being too stupid to imagine and much less to invent them. But I have nothing to do with the future. If there ever will be a flying machine capable of carrying not only man but other weight with it, I at present cannot conceive it. There are certain fixed principles in nature we cannot ignore. We cannot pull ourselves yet through space by our own boot straps, and we cannot leap from the top of a house without climbing on the top first."

"Why not take the bumblebee model and try it?"

"Nature made the bumblebee with motive power enough to carry its own weight and no more. Why it did not give the bumblebee more power I cannot explain ; it is beyond the comprehension of my very finite mind. Man was not constructed with wings, and so he has to wait and solve the problem which nature gave to the bumblebee and birds."

Future of the Phonograph.

"Do you think the phonograph will ever be universally used?"

"I know a number of men who at first did not like it, but now they constantly use it and save three or four hours of valuable time each day. The business man can get down to his office and talk off enough in half or one hour to his phonograph to keep five or six typewriters busy three or four hours. If that is not a wonderful time saver I would like to see it beaten. It is all well and good for a man to say that he can dictate rapidly to a stenographer ; but no matter how fast he talks to a phonograph it is all there, and anyone can hear and write it out afterwards. I predict that phonographs will entirely change the present system of answering business letters and writing communications. It is one of those inevitable things that prejudice and a lingering desire not to adapt a new method cannot affect. Look how the telephone is used now, and how it facilitates business. Well, the phonograph will soon be in vogue, and people will wonder why they had never used them before. It is one of the greatest labour-saving machines."

New Order in Telegraphy.

"Do you believe that the present style of telegraphy will soon be done away with?"

"Yes, but not until the old timers have disappeared. The operators now have a deep-seated prejudice against any inventions that will simplify telegraphy. But some of the inventions have already been made, and it is only a question of time when a man can rush into a telegraph office, scratch off a note to his wife in Chicago, and the exact duplicate of his note will be delivered over the wire to his wife. This will not be all by any means, but maps, pictures (newspaper pictures) will be transmitted promptly by wire. These new inventions will be for the coming generation to see in practical use. The old stagers will fight, of course, to keep the new order of things from coming rapidly into practical use, because it will interfere with their occupation."

After Dinner, Rest.

At six o'clock Mr. Edison stops work and goes home to dinner. The evening is spent in a drive or in chatting with some of the callers who constantly overrun the place. There is no restriction put upon visitors. A great many hundred curiosity seekers visit Llewellyn Park just to catch a glimpse of the inventor. Sometimes they succeed and many times they do not, for Edison is only human after all, and his nature is a bit perverse. By midnight the house is in darkness, except on some special occasion, when the light burns long in the library, and then it may be known that the great inventor has something on his mind, and is trying to solve an intricate problem. But as a rule his life is methodical. He goes to bed in good season, and gets up betimes.

He works hard all day and sleeps like a ploughboy at night. He seldom goes away from his home, and those who want to see him on important matters must journey out to him. He dislikes publicity very much. He has never been seen at a great public banquet in New York or elsewhere, and he finds little to interest him in the theatre or opera, although he is a great lover of music. In addition to all his other accomplishments he plays very prettily on the piano, and often passes an hour in that amusement. Perhaps while his fingers are wandering over the ivory keys his mind is in another land, where shadows become realities, and where by the touch of his magic wand he may bring forth some great invention that will benefit the entire human race.

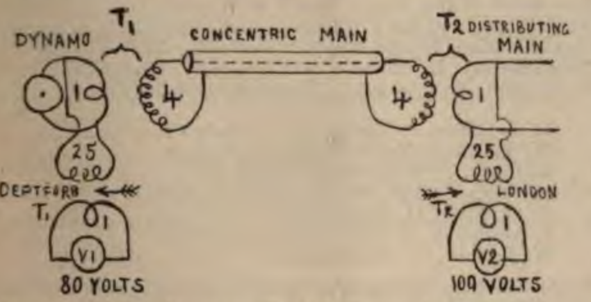
He would be wise indeed who could say what Edison will do next.

PHYSICAL SOCIETY.—Dec. 12, 1890.

Prof. W. E. Ayrton, F.R.S., President, in the chair.

Mr. Shelford Bidwell, F.R.S., showed "**Some Experiments with Selenium Cells.**" The crystalline variety of selenium was, he said, most interesting to physicists, owing to its electrical resistance being greatly diminished by light. This property was shown experimentally with different forms of cells, the construction of which were explained. The form recommended was that in which two copper wires are wound near each other round a strip of mica, and the spaces between the wires filled with selenium. The wires form the terminals of the so-called "cell," which before being used is annealed for several hours at a temperature above 200deg.C. Many such cells were made in 1880, 1881, and their sensitiveness to light remained unimpaired during 1882. In 1885, however, several were found less sensitive, and others totally useless; only one out of thirteen retained its sensibility till September, 1890. The loss of sensitiveness, Mr. Bidwell believes due to an excessive amount of selenide of copper being formed, for although some selenide is essential to the satisfactory working of the cell, too much is fatal to its action. The selenide of one defective cell was electrolysed, red tufts of amorphous selenium appearing on the anodes. A white substance resembling moist calcium chloride was also present; this he believed to be oxide or hydroxide of selenium. Small polarisation currents had been obtained from selenium cells. A lecture apparatus illustrating the properties of selenium cell was exhibited. It consisted of a cell connected in series with a relay and a battery. The relay was arranged so that it might either ring a bell or light an incandescent lamp. When the bell was joined up it remained silent so long as the selenium cell was illuminated, but on screening the cell the bell rang. By using various coloured glasses as screens, the effect was shown to be due to the red and yellow rays. A similar experiment with the glow lamp was very striking, for on turning down the gas lamp illuminating the cell the electric lamp lighted, and was extinguished on turning up the gas. This demonstrated the possibility of an automatic lamplighter which would light or put out lamps according as they are required or superfluous. Amongst the other practical applications suggested were announcing the accidental extinction of railway signal lamps or ships' lights, and the protection of safes and strong-rooms. **Prof. Minchin** said he had lately constructed cells of a different kind to those shown by Mr. Bidwell, and found that they gave an E.M.F. when exposed to light. For his purposes the long annealings, etc., were quite unnecessary, and a complete cell could be made in 10 minutes. One of his cells gave an E.M.F. of over one volt as measured by an electrometer, by the light of a fog. Their promptness of action falls off in a day or two, but if they are kept on open circuit a week has no effect on the final E.M.F. On closed circuit, however, they deteriorate. **Prof. S. U. ickering** said both oxides of selenium were deliquescent, and the ithor's conclusion as to the white substance formed by electrolysis was probably correct. **Prof. S. P. Thompson** believed Prof. Graham Bell had tried platinum instead of copper, and found that the selenium cracked off in annealing. He also found that it was only necessary to carry on the annealing until the characteristic slate colour appeared. Mr. Bidwell's experiments, he said, showed the possibility of seeing at a distance, and had also suggested to him that the effect of screening might be utilised for driving a completely detached pendulum electrically. **Prof. Forbes** said that silver sulphide when electrolysed presented appearances resembling those noticed by Mr. Bidwell in copper selenide. In reply to questions from the president and Prof. Perry, as to whether the low resistance and unsensitiveness of old cells was due to moisture, **Mr. Bidwell** said drying them had no effect, but baking restored the resistance, but not their sensitiveness. Speaking of the effect of annealing cells, he said this reduced their resistance considerably. Prof. Graham Bell, he believed, gave up using platinum because the resistances of such cells were very high.

Mr. James Swinburne read a paper on "**Alternate-Current Condensers.**" It is, he said, generally assumed that there is no difficulty in making commercial condensers for high-pressure alternating currents. The first difficulty is insulation, for the dielectric must be very thin, else the volume of the condenser is too great. Some dielectrics 0·2 mm. thick can be made to stand up to 8,000 volts when in small pieces, but in complete condensers a much greater margin must be allowed. Another difficulty arises from absorption; and whenever this occurs the apparent capacity is greater than the calculated. Supposing the fibres of paper in a paper condenser to be conductors embedded in insulating hydrocarbon, then every time the condenser is charged the fibres have their ends at different potentials, so a current passes to equalise them and energy is lost. This current increases the capacity. One condenser made of paper boiled in ozokerite took an abnormally large current, and heated rapidly. At a high temperature it gave off water, and the power wasted and current taken gradually decreased. When a thin plate of mica is put between the foils, it heats excessively, and the fall of potential over the air films separating the mica and foil is great enough to cause disruptive discharge to the surface of the mica. There appears to be a luminous layer of minute sparks under the foils, and there is a strong smell of ozone. In a dielectric which heats, there may be three kinds of conduction—viz., metallic, when an ordinary conductor is embedded in an insulator; disruptive, as probably occurs in the case of mica; and electrolytic, which might occur in glass. In a transparent dielectric, the conduction must be either electrolytic or disruptive, otherwise light vibrations would be damped. The dielectric loss in a cable may be serious. Calculating from the waste in a condenser made of paper soaked in hot ozokerite, the loss in one of the Deptford mains came out 7,000 watts. Another effect observed at Deptford is a rise of pressure in the mains. There is as yet no authoritative statement as to exactly what happens, and it is generally assumed that the effect depends on the relation of capacity to self-indication, and is a sort of resonator action. This would need a large self-induction, and a small change of speed would stop the effect. The following explanation is suggested. When a condenser is put on a dynamo the condenser current leads relatively to the E.M.F., and therefore strengthens the field magnets and increases the pressure. In order to test this the following experiment was made for the author by Mr. W. F. Bourne. A Gramme alternator was coupled to the low-pressure coil of a transformer, and a hot-wire voltmeter put across the primary circuit. On putting a condenser on the high-pressure circuit the voltmeter wire fused. The possibility of making an alternator excite itself like a series machine by putting a condenser on it, is pointed out. **Prof. Perry** said it would seem possible to obtain energy from an alternator without exciting the magnets independently, the field being altogether due to the armature currents. **Mr. Swinburne** remarked that this could be done by making the rotating magnets a star-shaped mass of iron. **Sir W. Thomson** thought Mr. Swinburne's estimate of the loss in the Deptford mains was rather high. He himself had calculated the power spent in charging them, and found it to be about 16 h.p., and although a considerable fraction might be lost, it would not amount to $\frac{9}{10}$ths. He was surprised to hear that glass condensers heated, and enquired whether this heating was due to flashes passing between the foil and the glass. **Mr. K. P. Trotter** said Mr. Ferranti informed him that the capacity of his mains was about one-third microfarad per mile, thus making $2\frac{1}{3}$rd microfarads for the seven miles. The heaping up of the potential only took place when transformers were used, and not when the dynamos were connected direct. In the former case the increase of volts was proportional to the length of main used, and 8,500 at Deptford gave 10,000 at London. **Mr. Blakesley** described a simple method of determining the loss of power in a condenser by the use of three electrodynamometers, one of which has its coils separate. Of these coils one is put in the condenser circuit, and the other in series with a non-inductive resistance, r, shunting the condenser. If a_2 be the reading of a dynamometer in the shunt circuit, and a_3 that of the dynamometer, the power lost is given by $r\,(C\,a_3 - B\,a_2)$ where B and C are the constants of the instruments on which a_2 and a_3 are the respective readings. **Prof. S. P. Thompson** asked if Mr. Swinburne had found any dielectric which had no absorption. So far as he was aware, pure quartz crystal was the only substance. **Prof. Forbes** said Dr. Hopkinson had found a glass which showed none. **Sir W. Thomson**, referring to the same subject, said that many years ago he made some tests on glass bottles, which showed no appreciable absorption. Sulphuric acid was used for the coatings, and he found them to be completely discharged by an instantaneous contact of two balls. The duration of contact would, according to some remarkable mathematical work done by Hertz in 1882, be about 0·0004 second, and even this short time sufficed to discharge them completely. On the other hand, Leyden jars with tinfoil coatings showed considerable absorption, and this he thought due to want of close contact between the foil and the glass. To test this he suggested that mercury coatings be tried. **Mr. Kapp** considered the loss of power in condensers due to two causes—first, that due to the charge soaking in; and second, to imperfect elasticity of the dielectric. Speaking of the extraordinary rise of pressure on the Deptford mains, he said he had observed similar effects with other cables. In his experiments, the sparking distance of a 1,400-volt transformer was increased from $\frac{13}{16}$in. to 1in. by connecting the cables to its terminals. No difference was detected between the sparking distances at the two ends of the cable, nor was any rise of pressure observed when the cables were joined direct on the dynamo. In his opinion, the rise was due to some kind of resonance, and would be a maximum for some particular frequency. **Mr. Mordey** mentioned a peculiar phenomenon observed in the manufacture of his alternators. Each coil was tested to double the pressure of the complete dynamo, but when they were all fitted together their insulation broke down at the same volts. The difficulty had been overcome by making the separate coils to stand much higher pressures. **Prof. Rucker** called attention to the fact that dielectrics alter in volume under electric stress, and said that if the material was imperfectly elastic some loss would result. The **President** said that as some doubt existed as to what Mr. Ferranti had actually observed, he would illustrate the arrangements by a diagram.



Explanation of diagram: T_1 and T_2 are large transformers; t_1 and t_2 are small transformers for voltmeters V_1 and V_2. The numbers 1, 4, 1, 25, represent their conversion ratios.

Speaking of condensers, he said he had recently tried lead plates in water to get large capacities, but so far had not been successful. **Mr. Swinburne**, in replying, said he had not made a perfect condenser yet, for although he had some which did not heat much, they made a great noise. He did not see how the rise of pressure observed by Mr. Ferranti and Mr. Kapp could be due to resonance. Mr. Kapp's experiment was not conclusive, for the length of spark is not an accurate measure of E.M.F. As regards Mr. Mordey's observation, he thought the action explicable on the theory of the leading condenser current acting on the field magnets. The same explanation is also applicable to the Deptford case, for when the dynamo is direct on, the condenser current is about 10 amperes, and this exerts only a small influence on the strongly magnetised magnets. When transformers are used the field magnets are weak, whilst the condenser current rises to 40 amperes. Mr. Blakesley's method of determining losses was, he said, inapplicable, except where the currents were sure functions of the time; and, consequently, could not be used to determine loss due to hysteresis in iron, or in a transparent dielectric.

Mr. Swinburne's "**Note on Electrolysis**" was postponed till next meeting.

THE JUNIOR ENGINEERING SOCIETY.

PROF. S. P. THOMPSON ON ELECTROMAGNETIC MECHANISMS.

(*Concluded from page 477, Vol. VI.*)

In moving under the stress of the magnetic field, the armature of an electromagnet performed mechanical work. The work done would, of course, be the product of the displacement into the average force. One was led thus to institute a comparison between the work done in the stroke of an ordinary steam engine piston and the work done by the armature of an ordinary electromagnet. In neither case was the force uniform from end to end of the stroke. With the piston the pressure rose very rapidly at the beginning of the stroke, continued at its maximum for a little while, and then fell continuously to the end of the stroke. In like manner, the magnetic stress which urged the armature varied from end to end of the stroke, but in a wholly different manner. At the beginning of the stroke, when the armature was at some distance away from the fixed core, the stress was small. (This was explained by means of a magnet and armature.) If the armature approached closer, there was a still larger magnetic flux, and when it was placed in close contact they had still greater flux of magnetic lines, and therefore the stress per square inch was greater. At the beginning of the stroke, when the armature was at some distance away from the fixed core, the stress was small, as it approached the magnetic field became more intense, and the stress therefore was greater. The range of motion in the case of ordinary electromagnets was extremely limited, and could be measured by 10ths or even 100ths of an inch. That was due simply to the smallness of the stress when any considerable thickness of air had to be passed. This disadvantage was so considerable that the late Robert Stephenson in 1866 gave this as a reason why electricity could never compete with steam power. He said that they might liken an electromagnet to a steam piston with an enormously large area of piston, but a very short stroke, which was very undesirable mechanically. The coil and plunger form of magnet had a much greater range of motion, but feeble average force, and was more analogous to the steam engine piston and cylinder. (Magnet shown in action.) Page constructed his motors on this principle in 1850. With a cylindrical plunger the length of the stroke and the distribution of the force between the beginning and end of the stroke depended not only upon the length of the tubular coil, but on the length and shape of the plunger. If the plunger was not greater than the length of the coil, it reached the position of maximum pull when it was immersed about half its own length in the coil. In all cases where a soft iron armature was used, the electromagnet was only single acting—that was to say, in mechanisms of this kind you must cut off the current to allow of the armature being pulled back by a spring. Exceptions to this rule were polarised mechanisms, wherein plungers or armatures which had been previously magnetised or were permanently magnetised were used. Such apparatus could be made double acting. Telegraph relays and single-ringing bells to work with alternate currents were examples.

To the electrical engineer the electromagnet with its armature constituted the central organ of all electromagnetic machinery. Just as the mechanical engineer studied indicator diagrams to ascertain what went on in the cylinder, so the electrical engineer must also use diagrams of a certain kind to enable him to trace the increased saturation of the iron core, ascertain its retentiveness, etc. Far as the analogies between the electromagnet and the steam engine had been traced, they might be carried one stage further. The principle of reversibility held good of the electromagnet as well as the steam engine cylinder. He did not mean the mere mechanical reversibility of function, but the very same mechanism was capable of serving the inverse function of employing mechanical power to compress steam or air. The pump was, in fact, the inverse of the steam engine. Its action was merely the action of the engine reversed. In the engine, heat was converted into work, or, in other words, entropy was let down from a high temperature to a low one, and furnished mechanical energy. On the other hand, energy furnished by a mechanical system was employed to transfer entropy from a low temperature to a high one, as in freezing apparatus. The modern dynamo was simply an electric engine, a combination of iron cores and copper coils capable of serving either as generator of currents, or mechanical motor worked by currents.

He must, however, return to the principle of the magnetic circuit, and restate it. The number of magnetic lines that would be evoked in any given circuit was directly proportional to the circulation of the surrounding electric current, and inversely proportional to the magnetic reluctance of the iron and air gaps of the circuit. It was usual to specify the circulation of the current in ampere-turns, meaning by that the amperes multiplied by the turns of wire in the coil. The reluctance of the magnetic circuit had to be calculated in separate parts, to be added together afterwards, allowance being made for leakage of magnetic lines. All known substances possessed permeability for magnetic lines, none having yet been discovered that were impermeable. Iron, nickel, and cobalt had a relatively large and variable permeability, unlike the vast majority of media, which had a constant and small permeability not differing sensibly from that of vacuum. Of the above-mentioned metals iron was the only one of importance, different specimens of which differed widely in permeability. Moreover, a sample of iron that had been well magnetised was much less permeable than one which had not been well magnetised—it became more impermeable the more it was permeated. Approximately the permeability of a specimen was proportional to the difference between the actual magnetic flux through it, and the maximum flux that could be forced through it. A specimen of annealed wrought iron when permeated with 18,000 lines per square centimetre was practically saturated, but at 17,000 lines per square centimetre had a permeability of 161, and at 16,000 its permeability was 320. The intensity of the magnetising force at any point, generally denoted by H, was often expressed by saying that it would produce H lines per square centimetre, if it was acting on an air core. If a core of iron was substituted for air, a larger flux of lines per square centimetre would be produced by the same magnetic force. This larger number expressed the degree of magnetisation of the iron, and was usually denoted by the letter B. The ratio of B to H expressed the permeabilty of the iron at that particular stage of magnetisation. To ascertain the magnetic properties of any specimen, a series of observations must be made with various values of H. In any complete observations, a number of such series must be made at different temperatures; as certain materials—notably alloys of iron and nickel—lately investigated by Dr. John Hopkinson changed their magnetic properties when heated. A series of observations made by Dr. John Hopkinson were represented by the curves in the diagram, Fig. 1.

Two liberties had been taken with this diagram. In the first place, the numbers plotted out were the numbers of magnetic lines per square inch, instead of per square centimetre. Secondly, the magnetic forces were plotted vertically, and the resulting induced magnetism horizontally, conversely to the usual method. The curve that started from 0 represented the set of observations made with magnetic forces, gradually increasing to about $H_{\prime\prime} = 170$, when the resulting number of magnetic lines per square inch in the iron was about 100,000. It would be noticed that when the magnetising force, $H_{\prime\prime}$, approached the value of 100, the curve became very steep, any further increase producing relatively little increase in the magnetisation.

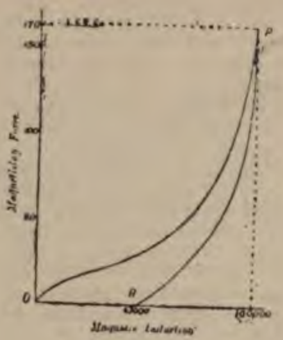


FIG. 1.

The second curve represented the result of their decreasing the magnetising forces back to zero, when there remained behind a residual magnetism of no fewer than 47,000 lines per square inch. To remove these would require the application of a reversed or negative magnetic force of about $H_{\prime\prime} = -13$. Applying the principle of the indicator diagram to these curves, it would be seen that the area below the first of them down to the zero line, and bounded on the right by the ordinate of the point P, represented the integral product of magnetic force into magnetisation, and was consequently proportional to the work done per cubic inch of the iron in bringing about the magnetic state of things implied by the position on the diagram of point P. Similarly, the area under the descending curve represented the work restored in the demagnetising of the specimen down to the state of things represented by the point R, when the magnetising force had been removed. The narrow area enclosed between the curves represented the work not so restored, and for the expenditure of which the residual magnetism was all there was to show. If the magnetising forces were carried through a complete cycle of alternations from $+H_{\prime\prime}$ to $-H_{\prime\prime}$ and back, the resulting magnetisation went through a corresponding cycle, with the result that a definite closed area was completed between the curves in the diagram, Fig. 2. Where there was no lagging in phase of the magnetisation behind that of the magnetising force, the ascending and descending curves would coincide instead of enclosing an area. The phenomena of lag had been studied by Prof. Ewing and Dr. John Hopkinson, to the former of whom was due the term hysteresis, to denote the lagging of effects behind the phase of their causes. Hysteresis was in magnetic what molecular friction was in elastic problems, always the cause of work being wasted.

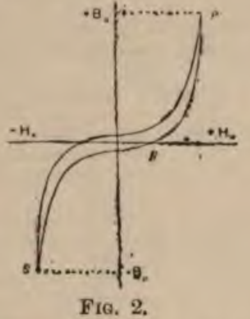

FIG. 2.

Prof. Thompson then proceeded to illustrate by a few experiments one or two of the principles of the magnetic circuit; showed Mr. Bidwell's experiment of the repulsion of two pendulums hung at either end of a hollow coil by the plungers inside it; referred to numerous electromagnets by Joule, Sturgeon, Froment, Houdin, Le Roux, Dub, etc.; alluded to electromagnetic tools, beginning with dentists' drills and Mr. Latimer Clark's device for divers to work on sunken ships, and passing on to the tools introduced and devised by Mr. F. J. Rowan, of Glasgow, magnetic separators, electromagnetic locks, etc.; and finished by defining the "electromagnetic engineer."

They would observe his use of the double adjective. There was no such thing as an electrical engineer pure and simple. What was wanted was an electromagnetic engineer, one who knew something about the way in which electricity worked magnets. To be able to make things electric-tight was more important than to be able to make things gas-tight or heat-tight, and more difficult. The art of insulation not only included a great deal of electrical, but also a great deal of mechanical knowledge. When they began to work from central stations that were not central but "excentric," they had to deal with great pressures needing high insulation to prevent sparks piercing it.

He had been trying to arrange electromagnetic mechanisms in some categorical order so as to arrive at connecting links. Prof. Willis, 40 years ago, and Prof. Roulan, of Berlin, 20 years ago, did this for mechanical mechanisms, and what had been done for them ought to and would be done for electromagnetic mechanisms. He had not yet succeeded in finding any rational classification. He had worked out a symbolism, and hoped to publish it some day, and then he might get a little more light upon the synthesis and analysis of electromagnetic mechanisms generally. But this kind of thing did not come down straight like an inspiration; it took years to work out. Systematisation was of the highest importance, however, because he felt certain that, great as were the advances that had been made, the systematic study of the theory of electromagnetic mechanism would lead them on to greater advances in the not distant future.

On the proposition of Mr. Wells, a very hearty vote of thanks was accorded to Prof. Thompson for his address.

NEW COMPANIES REGISTERED.

New Zealand Electrical Syndicate, Limited.—Registered by Beyroux, Phillips, and Golding, 99, Cannon-street, E.C., with a capital of £30,000 in £10 shares. Object: to acquire charters, concessions, privileges, and other grants for the manufacture and employment of electric lighting, etc., in New Zealand, Victoria, New South Wales, North, South, or Western Australia, Tasmania, New Guinea, and the Fiji Islands, and particularly to acquire the central stations for the supply of electricity erected by the Gulcher (New) Electric Light and Power Company, Limited, in the city of Wellington, New Zealand. The first subscribers are:

	Shares.
D. de Castro, 6, New-square, Lincoln's Inn	1
W. Turnbull, Mount Hanley, Sydenham	1
R. Pryor, 79, Gracechurch-street, E.C.	1
M. S. Vanderbyl, 187, Queen's-gate, S.W.	1
H. Grewing, 14, Austinfriars	1
J. Alexander, 3, Great Winchester-street	1
W. Farmer, 48, Aldermanbury	1

There shall not be less than three nor more than seven Directors. The first are D. de Castro, H. Grewing, M. S. Vanderbyl, and J. E. Williams. Qualification and remuneration not specified.

CITY NOTES.

Resignation.—It is stated that Mr. F. C. Bell has resigned the office of managing director of Bell's Asbestos Company, Limited.

Brazilian Submarine Telegraph Company.—The traffic receipts of the Company for the week ended December 26 were £4,441.

Western and Brazilian Telegraph Company.—The traffic receipts of this Company for the week ending December 26 were £3,453.

Award.—Messrs. Day and Co., of London, have been awarded a silver medal for dynamo and fittings shown at the Western Counties Art and Industrial Exhibition, Plymouth.

Crossley and Son.—The Directors recommend a dividend of 10s. per share (less income tax), which, with the interim dividend paid in August last, is equal to 7½ per cent. per annum for the past year.

West India and Panama Telegraph Company.—The receipts of the Company for the half-month ended December 15 were £2,499, against £2,835. The August receipts, estimated at £4,950, realised £5,013.

Reuter's Telegram Company.—At an extraordinary general meeting of this Company on December 24, the resolutions passed at a previous meeting (*vide E. E.*, December 12) were unanimously confirmed.

Business Notice.—We are informed that the Eschweiler Wire Industry Company, Limited (Germany), manufacturers of wire rods, rolled and drawn wire, wire nails, etc., have appointed Messrs. Künster and Co., 11, Queen Victoria-street, E.C., their sole agents in this country.

COMPANIES' STOCK AND SHARE LIST.

Name	Paid.	Price Wednesday
Anglo-American Brush	—	1¾
— Pref.	—	2
India Rubber, Gutta Percha & Telegraph Co.	10	19½
House-to-House	5	5
Metropolitan Electric Supply	—	8
London Electric Supply	5	2

Crompton & Co., Pref.	—	5½
National Telephone	5	4½
Electric Construction	10	7½

NOTES.

The Brentford Guardians have provided telephonic communication between their schools and the workhouse.

Westminster Supply Company.—This company hope to supply current from their Davies-street station by next March.

Sweden.—At Ballnoos in Sweden a waterfall is utilised to drive the machinery for supplying current to 400 incandescents of 16 c.p., used for public and private lighting.

Death.—Prof. Casey, LL.D., F.R.S., Fellow of the Royal University of Ireland, died in Dublin on Saturday last. He was 70 years old, and a distinguished mathematician.

Telephone in Lincolnshire.—Telephonic communication is about to be opened up between Lincoln, Gainsborough, and Doncaster, by the National Telephone Company.

Gravesend.—The Town Council last week discussed the present unsatisfactory condition of the public lighting in the town, and strongly condemned the supineness of the gas company.

The Tory Island Cable.—A telegram from Lloyd's signal station at Tory Island, dated Dunfanaghy, January 4, states that Lloyd's Tory Island cable has been thrown open to the public.

Derby.—The Town Council have decided to obtain a report from Sir Frederick Bramwell on the subject of electric lighting for the town under the Derby order, at a cost of 75 guineas.

Reform Club.—The contract for the fitting up of the Reform Club has been given to Messrs. Verity and Sons. The installation is to comprise 500 lights, and the current will be supplied from the St. James's and Pall Mall central station.

Brush Lights in the City.—The Brush Electrical Engineering Corporation have taken the corner near the Mansion House Station, 55, Queen Victoria-street, as their offices and central premises for the City lighting enterprise.

The Andaman Islands.—The Meteorological Reporter to the Government of India has recorded his opinion that it is almost absolutely necessary for the warning of the Bengal and Madras coasts that a cable to the Andaman Islands should be laid.

Dewsbury.—The Town Council propose to spend £50,000 in carrying out electric light works under their order; this is estimated to be considerably more than will be required for the compulsory area, and sufficient to deal with extensions in the future.

Holland House, Kensington.—The Wenham Company have obtained the contract for the lighting of Holland House, the residence of Lord H. Chester. This company, it may be remembered, carried out the lighting at Craig-y-Nos Castle, for Madame Patti.

Dublin.—We understand that the committee of the Corporation of Dublin have recommended the tender of the Electrical Engineering Company of Ireland for acceptance. The decision has not been definitely announced, but official recognition will doubtless follow.

Appointment Vacant.—An assistant mechanical engineer is wanted for the Government powder factory at Ishapore, India. He must be efficient in electrical engineering. The salary and other particulars will be found in our advertisment columns.

Appointment.—Mr. M. C. Olsson, who was associated with Mr. Massingham for three years in his electrical works at Taunton, and for the past two years has been chief electrical engineer of some large works on the Continent, has been appointed to take charge of the Bath central station.

Northampton.—The Council have decided that a contract upon the same terms and conditions as applied to the western portion of the new Town Hall Municipal Buildings be entered into with the Northampton Electric Light Company for the electric lighting of the remainder of the buildings.

Calendar.—Messrs. Appleton, Burbey, and Williamson, of 91, Queen Victoria-street, E.C., send us a novel calendar for office use in the shape of a porcelain slab, the lower half of which is roughed for pencil memoranda, while the top half contains the calendar, with revolving date plate for weekly adjustment.

Companies Wound Up in 1890.—The following companies were wound up voluntarily during the past year: Australasian Electric Light, Power, and Storage Company, Maxim-Weston Electric Company, Whitehall Electric Supply Company, Woodhouse and Rawson Electric Contract and Maintenance Company.

Barnsley.—The Town Council are advertising for tenders for erecting their central station buildings, which will be situated in Midland-street and Queen's-road. Mr. J. H. Taylor, A.M.I.C.E., of St. Mary's place, Barnsley, is the architect, and tenders are to be sent in to him not later than 3 p.m. on the 16th inst.

Electric Traction in Sweden.—An electric tramway is about to be run in Stockholm, and one is also projected between the towns of Karlsland and Orebro. The mines in the district of Vormland are supplied with electricity both for lighting and power purposes, the generating machinery being driven by water power.

Kensington Town Hall.—An inauguration of the electric light at Kensington Town Hall was held yesterday evening in the shape of a *conversazione*. The lighting comprises several hundred electric lamps installed by Messrs. Baily and Grundy, the current for which is supplied from the Kensington and Knightsbridge Company's station.

Books Received.—"Electric Transmission of Energy," by Gisbert Kapp, C.E., third edition, revised, "The Specialist Series"; published by Whittaker and Co., 2, White Hart-street, Paternoster-square, E.C. "Electric Light Installations and the Management of Accumulators," Sir David Salomons, A.I.C.E.; sixth edition, revised and enlarged, same publishers.

Lectures.—Prof. W. E. Ayrton, F.R.S., will give a course of lectures on accumulators, electric lighting, electric traction, and the distribution of energy at the Central Institution of the City and Guilds Institute, on Mondays and Wednesdays, from 3 to 4 p.m., beginning next Wednesday, the 14th inst. Further particulars will be found in our advertisement columns.

Institution of Electrical Engineers.—The next meeting of the Institution will take place on Thursday, the 15th inst., when the president, Mr. W. Crookes, F.R.S., will deliver his inaugural address. On and after the 25th inst., the address of the Institution will no longer be 4, The Sanctuary, but Victoria Mansions, 28, Victoria-street, Westminster, S.W.

Messrs. W. H. Willcox and Co., of Southwark-street, S.E., send us their office calendar for this year, which is clearly printed in coloured inks, and besides affording the usual information as to dates, also has some neat illustrations of their manufactures, which comprise belting, piston packings, cylinder and dynamo oils, engineers' sundries, etc.

Madras.—The *Madras Times* hears that a gentleman who has arrived in Madras from England has submitted a scheme to the President of the Municipal Commission for lighting the city by electricity, and running electric tram-cars in it. He is supposed to be powerfully backed at home, and one of the promoters is in India negotiating with the authorities concerned.

Edinburgh Exhibition and Mr. Bapty.—On Tuesday, in the Edinburgh Court of Session, Lord Stormouth-Darling closed the record in the action by the liquidator of the Edinburgh Exhibition against Samuel Lee Bapty, the general manager of the exhibition, in which decree is asked for the sum of £500 which defender guaranteed to the funds of the exhibition.

Prague Exhibition.—It is proposed to hold an International Exhibition in Prague from May to October next. A section is to be devoted to machinery for the prevention of accidents, two of the groups in this section being devoted to transport and lighting, ventilation and fire-engines. Applications will be received by the Executive Committee, 55, Wenzelsplatz, Prague, up to the 31st inst.

Panama.—A French journal states that the Municipal Council of Panama has signed a contract for the fitting up of 43 arcs for street lighting. The company who are doing this work have also received orders for 300 incandescents for private lighting. We hope that electric lighting will fare better than the other enterprises with which the name of Panama is connected, but we have our doubts.

Theatre Lighting.—The electric installation at D'Oyly Carte's new theatre is now finished and in thorough working order. The theatre will be opened with considerable flourish of trumpets in about three weeks' time, and not the least successful of its many well thought out details is the very extensive electrical and steam engine arrangements which have been carried out by Messrs. Verity and Sons.

Owens College.—The following elections to fellowships have recently been made by the council for the year 1891. Bishop Berkeley Fellowships: W. R. Ormandy, in chemistry; and renewed for a second year to P. J. Hartog, B.Sc., in chemical physics. Honorary Research Fellowships: Gibson Dyson, Ph.D., in chemistry; J. L. Hoskyns Abrahall, B.A., Ph.D., in chemistry; C. H. Lees, M.Sc., in physics.

Diary for 1891.—We have received a copy of the pocket diary issued by the Eastern Telegraph Company. It contains a list of cable rates to different parts of the world, a calendar and diary, and several very well got-up maps of the cable systems of the world with their overland feeders. We have also to acknowledge the receipt of a useful paper knife, the blade of which carries a cable map and the handle a calendar.

Agra Water Works.—These works were opened by the Viceroy of India last month. The boiler-houses, engine-houses, pump-room, and purifier-room are lighted with 16-c.p. lamps. The machinery connected with the pumping and purifying of the water and the electric light has been supplied by Messrs. Easton and Anderson, Limited, of Whitehall, and has been erected by the contractors, Messrs. Marillier and Edwards, of Calcutta.

Dr. Stephan, the German Postmaster-General, celebrated his sixtieth birthday on Wednesday, and received from the Emperor William a photograph of himself, at the foot of which His Majesty wrote the following: "Intercommunication is the sign under which the world stands at the close of the nineteenth century. It breaks down the barriers separating one people from another, and establishes new relations among the nations of the earth."

Limerick.—It will be remembered that the Limerick Corporation allowed their application for an order to drop, so far as this session is concerned (*vide* our list of provisional orders applied for, *E.E.*, Dec. 26, p. 576). Now, however, they have been urged into action again by the desire of the Irish House-to-House Company to invade the town. Accordingly the Corporation have recently determined to apply for an order with the view of keeping the company out.

Telegraph Work in India.—Putting up lines in India is not all beer and skittles, as will be seen from the following: "There has been much sickness among the telegraph party working between Kan and Haka, the men employed on this section of the line having suffered in common with the Haka garrison from epidemic fever. On the Chittagong side the death from fever is reported of Mr. R. Rector, sub-assistant superintendent, an officer of great energy and resource."

Electrical Advertisements.—Outside the Pavilion Music Hall, in Piccadilly, a large electric sign has been fitted up with the word "Pavilion" in large glass letters. By an automatic arrangement the colours of the illumination are made to change every half minute. The idea is one that might be adopted in many situations where a prominent advertisement or notice is required, as one of the first facts to be remembered by advertisers is that anything moving or changing is far more attractive than a simple sign.

Mexborough.—At Wednesday's meeting of the Local Board, it was proposed that the electric light should be introduced. The total cost of the works was estimated at £2,055, and the annual expenditure would be about £300, including the services of an electrical engineer. The chairman (Mr. Tiptaft) said he was so satisfied with the electric light that he should strongly oppose the erection of new gas works. The electric light was an assured success, financially and otherwise. A definite scheme is to be laid before the next meeting of the Board.

Spiers and Pond.—As we mentioned some weeks ago, a large installation has been put down by Spiers and Pond, Limited, at their new premises in Water-lane, Queen Victoria-street, E.C. The offices and bakeries are lighted by some 300 lamps, and the market street in Water-lane by 22 arc lamps. The Holborn-viaduct Hotel is supplied from the same source by cables run along the railway, and 800 lamps are lighted in this hotel. The arcs make Water-lane, hitherto a somewhat gloomy thoroughfare, a really well-lighted and pleasant street to get about in.

Bridlington (Yorks.).—At a meeting of the Local Board on Tuesday, a joint committee of the members of the Prince's Parade and Lighting Committees, appointed to consider and report as to the best means of lighting the Prince's Parade during next summer, reported that, after going fully into the matter, they recommended that the walks and terraces be lighted by means of electricity, and colonnades, lavatories, etc., be lighted by gas, and that the committee visit certain districts where the electric light is in use, and further report as to the best system to adopt. After discussion the report was adopted.

London University.—The following passed the recent examinations for B.Sc. in experimental physics. First class: William Watson, scholarship, Normal School of Science; Alfred W. Porter, University College, Liverpool and

London; Owen G. Jones, City Guilds Central Institute. Third class: Harry E. Hadley, Arthur R. Hall Ingram, Mason College, Birmingham; Thomas P. Nunn, University College, Bristol; George A. Schott, Trinity College, Cambridge; Walter Thorp, Yorkshire and University Colleges; John T. Hewitt, Hartley Institute, Normal School of Science, and St. John's College, Cambridge.

Whipple's Reports.—We have received a copy of the December issue of these reports. In commenting on the way business has been conducted in the past and forecasting the future Whipple says: "There are already indications that electric companies are demanding shorter time on payments of their goods, that more of the legitimate and less of the wildcat sort of competition will be seen in the future, and that better business principles will be instilled into the methods of selling goods. Therefore out of the present evils will come good, and the electrical business will be more than ever one of the great trade institutions of America."

Electrical Bleaching Processes.—At a meeting of the East of Scotland Engineering Association, held at Edinburgh this week, Mr. J. B. Bennett, C.E., read a paper on "Papermaking Processes and Machinery," in which, after dealing with the historical development of paper manufacture, he referred to the materials and methods used in modern times. He described in detail the electrical processes which are being introduced for bleaching paper pulps, as well as textile fabrics, by which solutions, such as sea water, containing alkaline chlorides may be used for bleaching, and gave particulars of the preparation of wood pulps, which are now so largely used by papermakers.

The Sonnblick Observatory.—The death is announced of Herr Ignaz Rejacher, owner of gold mines at Kulm Saigurn, in the Rauris Valley, and originator of the Sonnblick Observatory, the most elevated in Europe. He commenced life as a peasant, but eventually became one of the chief promoters of science in Austria, and a great benefactor of the district in which he resided. The observatory is tenanted by a peasant who formerly worked in the above mines. During several months of the year he is, by the difficulties of his situation, cut off from personal association with the world, except by telephone. He hears each day living voices through this instrument, but otherwise he is isolated, and has only a dog for companionship.

New Continental Companies.—The Anglo-Austrian Bank of Vienna, and the firm of Siemens and Halske, of Berlin, have just formed three new electrical companies with headquarters in the former city. The first is the Austrian General Electricity Company, constituted, with a capital of £312,000, for the purpose of constructing and working central electric light stations. The second is the Electric Tramway Company, with a capital of £312,000, for the making and working of electric tramways, and the company have already acquired the Buda-Pesth electric tramway. The third is the International Compressed Air and Electricity Company, with the same amount of capital, and formed to work a concession obtained from the Vienna municipality for lighting the city by electricity.

The Telephone in Reading.—A local paper says: "The popularity of the telephone has much increased of late years in Reading under the present excellent management. There are no fewer than 181 connected with the exchange, and several other private residences and business establishments are shortly to have telephonic communication. There are also several private wires. The trunk line which will connect Reading with London is being rapidly pushed forward, and will probably be completed this year. There is practically a connection from London to Bracknell, and the line from the latter place to Wokingham is being constructed, while the necessary permission has been obtained to carry the wires to Farley, which is now the limit of the Reading centre in that direction."

Fire.—At 4.45 a.m. on Tuesday, the 6th inst., a fire broke out in the works of the Electrical Engineering Corporation at West Drayton. The outbreak was discovered by the stokers, who were getting up steam in the main fitting and machine shop. Two hydrants belonging to the company were got to work within a very short time, and efforts were made to keep the fire in check. This, however, proved to be beyond the powers of those present. The water supply was therefore utilised to save the adjoining buildings, and with success. The shop in which the fire originated was practically gutted, the damage being estimated at about £15,000, which is covered by insurance. We are assured by the managing directors of the corporation that the fire will not interfere with the execution of orders in hand, or that may be entrusted to them.

Conversazione.—On Tuesday next the Birmingham Midland Institute holds its annual *conversazione*, which promises to be very successful. Among the exhibits promised are: The Giffard gun, lent by the Giffard Gun Company; steam loop, an arrangement by which the exhaust steam from an engine can be returned to the boiler; lecture-room model of Sir William Thomson's quadrant electrometer, exhibited by Mr. G. W. Holbrook; Dr. Lodge's Leyden jar experiment, exhibited by Dr. Poynting, F.R.S.; photographs showing oscillatory discharge of a Leyden jar, lent by Mr. C. V. Boys, F.R.S.; mechanical designer—for producing a variety of designs by mechanical means, invented and exhibited by Mr. F. Iles, Highgate-street, Birmingham; also a newly-patented accumulator, invented by Mr. Drysdale, one of the institute students. Telephones will be provided by the National Telephone Company in connection with public performances in distant towns.

Birmingham and Midland Institute.—The report of the council of this institute states that Mr. G. S. Albright has added another to the many obligations under which the institute lies to him, in generously providing an installation of electric lighting in the metallurgical department. Formerly the laboratory, when all its furnaces and muffles were alight, and the place full of students at work with hot metal, the light they required being given by a free use of gas, became almost dangerously hot for those in it. We also learn from the same document that among the old students who have obtained appointments are Mr. W. P. Wynne, who has been made assistant professor at the Royal Norman School of Science, South Kensington; Mr. W. Tate, who has charge of one of the laboratories there; while yet another—Mr. A. E. Briscoe—has been appointed assistant to Profs. Thorpe and Rücker in their researches as to the local variations of the magnetic elements in different part of England.

Leeds.—At last Wednesday's meeting of the Leeds County Council, the town clerk (Sir Geo. W. Morrison) reported the receipt of plans and parliamentary notices, under the Electric Lighting Acts, 1882 and 1888, from the National Electric Supply Company, the Yorkshire House-to-House Company, and the Electric Installation Company. The Yorkshire Company, he said, proposed to light the whole borough; and the other two companies were seeking powers to supply electricity in the centre of the town. Ald. Harrison explained that the Council, after the decision they came to a few weeks ago not to supply electricity themselves, were in a different position from that in which they found themselves when similar notices last came before them. It was necessary that any objections to the notices should be submitted to the Board of Trade by the 15th of the present month. No detailed action would be necessary; but he proposed that the matter should be put into the hands of the Parliamentary Committee, so that a technical objection might be made. The Corporation would then have a *locus standi* on a future occasion. After some discussion, this suggestion was agreed to.

The Comprehensive International Wire Table. Mr. W. S. Boult has compiled and published a book containing a very comprehensive series of tables relating to wires. These tables are clearly printed and occupy some 50 pages. They relate to the diameter, area, gauge, weight. current, resistance, heat when cased, and heat when bare. The wires about which this information is tabulated range from 2·26in. to ·001in., altogether 469 different wires. Use has been made of the Silvertown tables, and of assistance rendered by Messrs. Glover and Co., and Kennelly's formulæ have been employed to calculate the heating of the wires. It might be worth while asking if Mr. Kennelly's formulæ have been generally or authoritatively adopted. We had supposed that at present such was hardly the case, and that doubts have been in more than one quarter expressed as to their accuracy. The figures, however, relating to heat form but a small proportion of the whole, and even if the formulæ be adversely criticised they certainly are sufficiently accurate in most cases for practical work. Altogether these tables should prove extremely useful and valuable, and Mr. Boult is to be congratulated on their production.

Institution of Civil Engineers.—On Friday last this institution reached its seventy-third anniversary, having been founded on the 2nd January, 1818. At this latter date six young men associated themselves together for mutual advantage, and from this small beginning sprang the present powerful institution. The presidents of the institution have been, successively, *Thomas Telford*, *James Walker*, *Sir John Rennie*, *Joshua Field*, *Sir William Cubitt*, *James Meadows Rendel*, *James Simpson*, *Robert Stephenson*, *Joseph Locke*, *George Parker Bidder*, Sir John Hawkshaw, *John Robinson McClean*, Sir John Fowler, Bart., K.C.M.G., Sir Charles Hutton Gregory, K.C.M.G., *Charles Blacker Vignoles*, Thomas Hawksley, *Thomas Elliot Harrison*, George Robert Stephenson, *John Frederic La Trobe Bateman*, William Henry Barlow, James Abernethy, Lord Armstrong, C.B., Sir James Brunlees, Sir Joseph William Bazalgette, C.B., Sir Frederick Joseph Bramwell, Bart., Edward Woods, and Sir George Barclay Bruce. The names in *italics* indicate those who are no longer living. The present president is Sir John Coode, K.C.M.G. The number of the various classes now on the books comprise 1,700 members, 2,880 associate members, 427 associates, 19 honorary members, and 927 students, together 5,953.

Leith.—At the meeting of the Town Council on Tuesday the minutes of a special meeting of the General Committee, held on December 30, showed that the committee had considered the Edinburgh Corporation electric lighting order, and had "expressed the opinion that if the Corporation of Edinburgh are to obtain such powers it should only be under the most ample protection to this burgh from any loss in the matter of the gas supply; and particularly that the proposed power to transfer the operation of the order to the Gas Commissioners, thereby making these Commissioners (involving the rates of Leith) financially responsible therefor, should not be effectual without the consent of the Corporation of Leith; and that there should be provision for any increase in the price of gas, or other loss in connection with the gas supply, being borne alone by Edinburgh, who are introducing the competitive light." The town clerk read the minutes of a meeting of the committee held on the same day as the Council meeting (Tuesday), in which was stated that the minute of the committee dated December 30 last had been amended to the effect that the proposed "loss clause" should only take effect in the event of the electric lighting order being administered otherwise than by the Edinburgh and Leith Gas Commissioners, with the consent of the Corporation of Leith. These minutes were agreed to.

Cambridge.—The Town Council at the last meeting decided to obtain powers to borrow £35,000 for electric lighting purposes. Although powers to borrow £35,000 are to be obtained, it is thought that a complete installation will cost from £20,000 to £22,000, such as will supply 3,000 incandescents of 16 c.p., which would allow 6,000 lamps to be wired, and 60 arc lamps of 1,500 c.p. for street lighting. Reference during the discussion of the question was made to the Bradford installation balance-sheet, which showed, allowing interest on outlay, £700 loss on three months' working; without interest, £11 profit; but this arose because Bradford only charged to customers 5d. per unit, a price admittedly too low, and in future Bradford would charge 6d. per unit, while Cambridge proposes to charge 8d. per unit. Any comparison of such charges must consider the difference in cost of coal for engines at Cambridge and Bradford. While the latter may make a fair profit the former could not at the same price. The gas company at Cambridge met the agitation for electric light by reducing the price of gas by 2d. per 1,000, showing their fear of the competition. Without doubt one consideration must be taken into account when making plans for electric lighting, and that is, to provide from the first for extension that shall enable the whole town to be supplied.

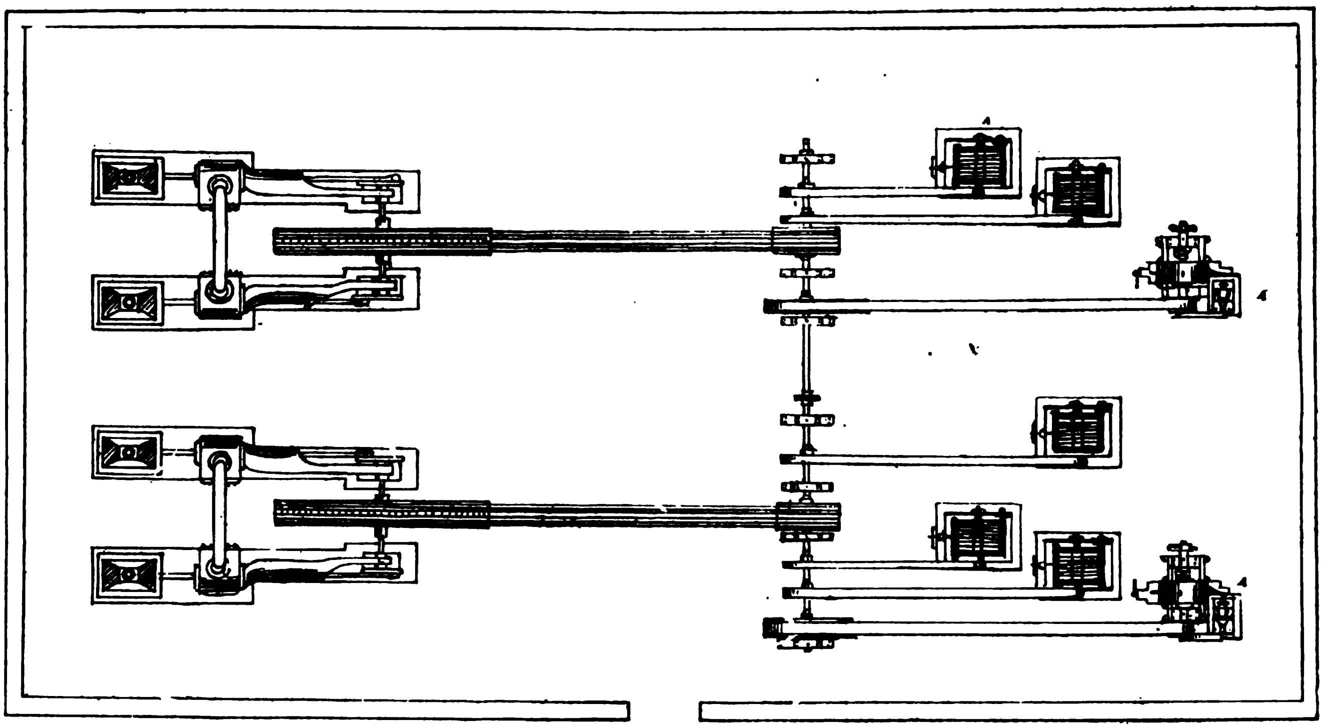
Preston (Lancs.).—At a recent meeting of the Town Council Alderman Birley, referring to the approval given by the Streets and Buildings Committee to the erection of several electric lights in various parts of the town, asked for some information upon the general subject of electric lighting. He hailed with great pleasure the introduction of the electric light, but he was afraid the gas company were not alive to its importance, or they would try to please their customers by supplying better light than at present; a remark which evoked unanimous expressions of approval. The town clerk, in reply to Alderman Birley, said that during the last session of Parliament there were two orders promoted. One was by the National Electric Lighting Supply Company, but they only dealt with a portion of the town, such as Fishergate, Friargate, Lune-street, Church-street, Market-place, and Lancaster-road. The other company, which got an order for the whole borough, was the Lancashire and Cheshire House-to-House Company. When the order of the National Company was going through it was made a condition by the Corporation that that company should in the coming session promote an order for the rest of the town, the object being, of course, to create competition. If the National Company did not go in for that order this session, it would leave a great portion of the town in the monopoly of the Lancashire and Cheshire Company. The order which Alderman Birley had seen advertised was to obtain that competition.

Birmingham.—The Birmingham Electric Light and Power Company is progressing with the work of supplying electricity within its area. The amount of work yet to be done in the streets is comparatively small, the laying of the buried heavy mains having been completed some time since, and during the last few days men have been busy at the manholes, threading through the culverts prepared for their reception the copper strips which form the lighter distributing mains. Not much of this work remains to be done. At the generating station in Albert-street fair progress is being made. The boilers are set, and the fixing of the engines is proceeding; but some portions of the work are at a standstill owing to the frost, which has made bricklaying difficult, and has absolutely stopped one essential part of the work—the completion of the chimney-stack. In the meantime every operation which the weather does not hinder is being pushed forward, and it appears likely that nothing but a serious prolongation of the frost will stand in the way of the fulfilment of the anticipation that the electric light will be in use by the end of this month. Orders for over 2,000 lights have been received, and this is considered very good for a company that has not yet commenced. The work already done by the company includes a large amount in the "wiring" of premises which are to be lighted, such as the Victoria Courts, the Grand Hotel, the Bank of England, Temple-row (premises of the late Staffordshire Joint-Stock Bank), the new building of the Prudential Assurance Company, in Corporation-street, and the Alliance Insurance Company's offices.

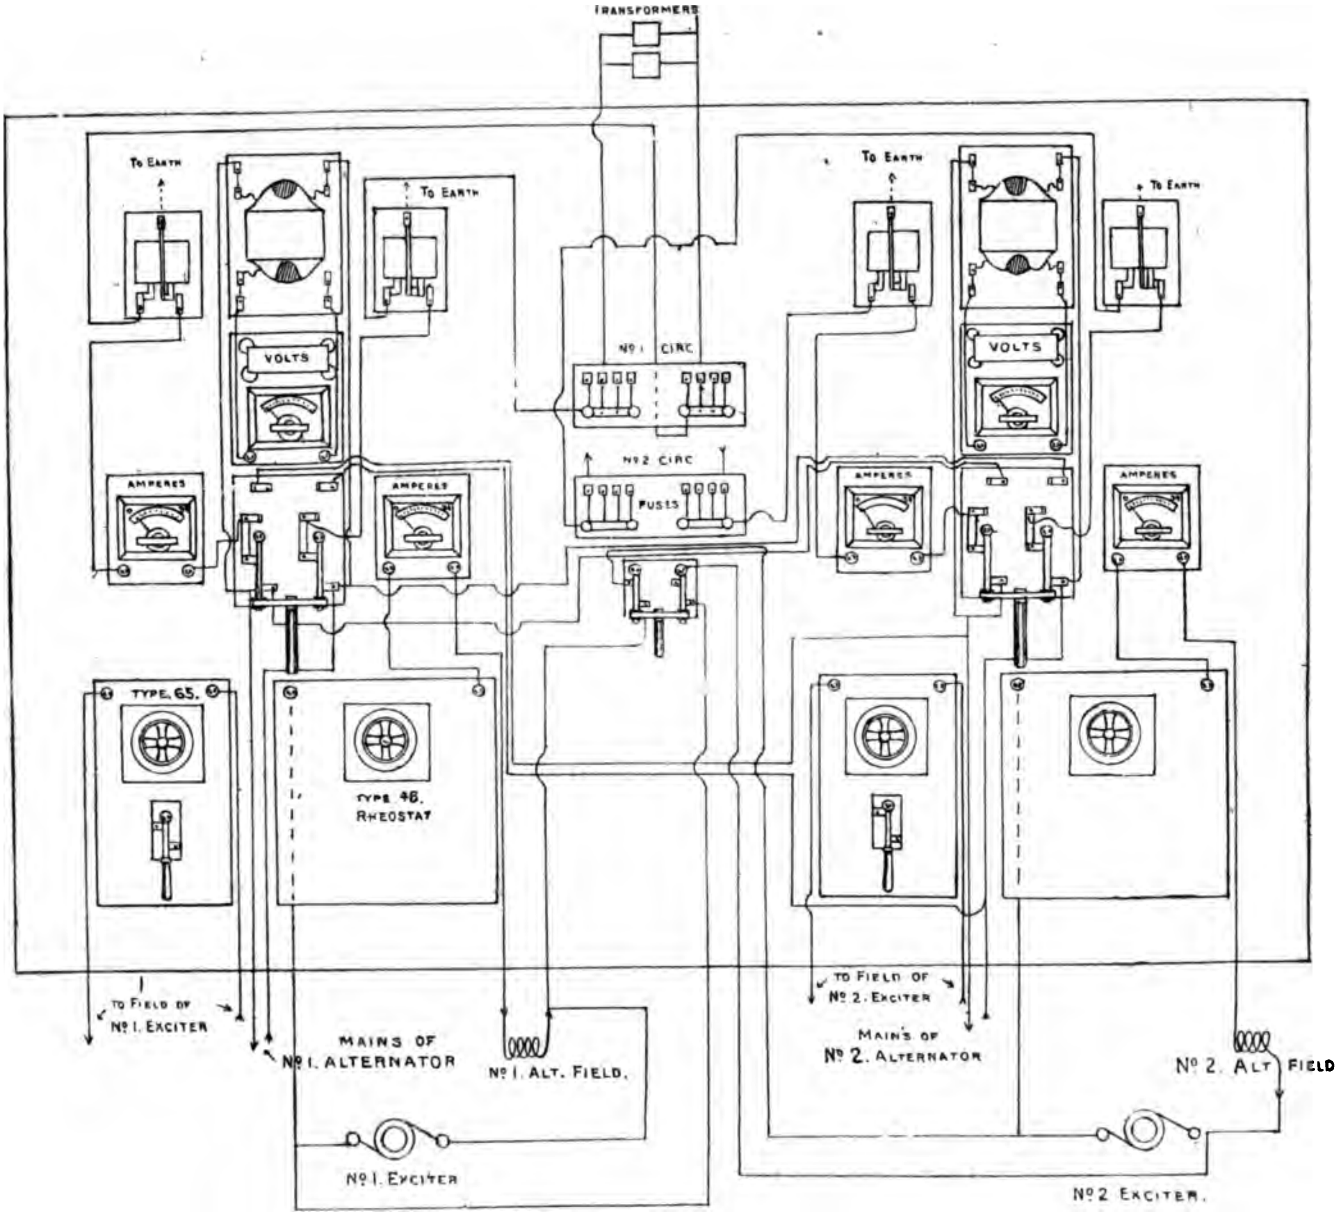
Newcastle-on-Tyne.—The application by the Newcastle Electric Light Company for the Town Council's sanction to an extension of the period covered by their order from seven to 42 years, came before the Council for decision on Wednesday, and gave rise to a lengthy discussion. Alderman Winter moved a resolution that the Council's consent be given, contending that they ought to afford a trading company all the facilities they could for lighting the town. He also mentioned that the company's charge for street lighting was 2d. less than that made to other consumers. Mr. Matthewson seconded the resolution. Mr. Temple said the application for the license was only a few months old, and the company knew then as much as they knew now. They got a license for seven years, and their only reason for seeking an extension of time was that they said they could not raise capital. Before the Council passed such a resolution, it required a great deal more careful consideration than it was likely to get there that day. A period of 21 years was quite long enough to let such a thing out of their hands without being able to alter it. He would move that the utmost limit of the granting of the license should not exceed 21 years. The Mayor said such a motion was not in order, and, after some further discussion, Mr. Temple formally moved that the meeting be adjourned for a month to enable the Council to negotiate with the company as to the length of period and the charge for the electric light. This was seconded. Alderman Hamond objected to a license being given for an indefinite period, which was virtually a monopoly, to any company. He was in favour of granting a license to the company for 21 years, but he thought that there should be a sliding scale to regulate the price, as with the gas company, according to the dividends. The consumer should have a share of the profits, as well as the producer. Alderman T. Richardson supported the adoption of Mr. Winter's resolution, wishing to promote the progress of science in the city, and the interests of the inhabitants. Mr. Temple had said that the company knew at first as much as they did now. They did nothing of the sort. It was a pure experiment then. They found now that they were obliged to lay down more extensive plant, and people would not go into a concern with such an insecure tenure. There was no monopoly. There was nothing in the provisions to prevent the Corporation from starting an electric supply on their own account. He hoped the Council would not stand in the way of progress in the city. The Council then divided on Mr. Temple's amendment that the matter be adjourned for a month, and it was carried by 31 votes to 18.

Practice in America.—Mr. C. E. Woods, writing in the *Electrical World*, says: "In reading the different papers devoted to the electrical interests, one cannot help noticing that most of the matter published in them bears upon the theoretical side of the question, and that very little space seems to be given to the plain, common everyday side of it. Now, while theorising is necessary, it should be remembered that in addition to theoretical problems we have some very practical ones to solve, and I will try to present some of them in this article, taken from the standpoint of a constructing electrician, which is my humble vocation, and I think my brother engineers will say I am right. While I lay no claim to being an electrical expert, I have had considerable experience in construction work, and I am sorry to say my work comes a long way from being satisfactory to myself for reasons that I will present later on. First, what is a constructing electrician or electrical engineer? He is the medium through which electricity in its various forms is introduced to an ignorant public. He is the one who must put into satisfactory operation the electric plants for light and power purposes. He is the one who must carry out the plans of half a dozen different men to obtain the desired result. He must learn when to take care of and operate his system, whatever it may be. He must be ready for any and all emergencies, and is supposed to be infallible; but in this respect it sometimes proves to be a case of misplaced confidence. But, poor fellow, he has much to contend with, and much trouble that is not of his own making, and the greatest of all is the everlasting desire of the American public for cheapness. This is a practical problem that some of the great and learned minds ought to endeavour to solve. It may be asked, What do you mean by cheapness? I mean the cheap material, cheap workmanship, and cheap labour that electrical engineers are obliged to use. We have as good material in our market as could be desired, but people won't pay for it—at least, as long as they can help it. I saw an article not long since in one of our leading papers telling how much better the material and work were in England than in America. Now, America has just as good material as can be procured, but American people won't pay for it as long as they are allowed to use cheap material, and just as long as the consumer can say what he shall pay and what kind of material shall be used in his particular installation will the electrical engineer be obliged to do poor work and use poor material. To be sure, the insurance companies have taken it up to a certain extent, but of a truth it doesn't go very far. And so to sum it up, in short, inside wiring in this country is, generally speaking, more a matter of dollars and cents than good work and material. I would suggest that if people will not do any different of their own accord, some means ought to be devised by which they will be forced to. If the insurance companies cannot enforce it let someone introduce a Bill carrying with it a set of rules and regulations for this purpose into the Legislature, and see if something cannot be accomplished in that way. Now when it comes to line work it is something dreadful to think about. There are absolutely no rules relative to this branch of the work that can be enforced, except in some few local instances; and of all the cheap unsightly work that ever was done the average line construction of to-day is, I believe, the worst. It comes of course from close competition between the various systems in some instances, but not always, for often local companies put up their own line work under the supervision of a man who knows little or nothing about it, hoping thereby to save something. But by so doing they make a grand mistake, which they sooner or later find out to their sorrow. This state of things will exist as long as local companies and manufacturers of different systems can pursue their individual methods in the matter."

INDIA.



Plan of Engines and Dynamos—Kidderpore Installation.



Main Switchboard—Kidderpore Installation.

The contract for lighting the new docks at Kidderpore, near Calcutta, has been placed in the hands of the Laing, Wharton, and Down Construction Syndicate, for whom, we believe, Mr. Hitchcock, their engineer, is about to proceed to India in order to superintend the erection of the plant. The illustrations given herewith show the arrangement of the apparatus, so far as dynamo-room and engine-house is concerned. The switchboard is also illustrated, and will be seen to be well arranged. The plant consists of two coupled horizontal long-stroke condensing engines, two Lancashire boilers, built by Messrs. Ransomes and Co., of Ipswich. The engines drive a length of steel countershaft by means of rope gearing. The pulleys on the countershaft are all fitted with a new patent friction clutch, designed, we believe, by Mr. A. Guy, so that any machine can be stopped or started as required. There are in all seven dynamos driven from the shaft, five of which are Thomson-Houston arc machines, the other two are Thomson-Houston composite field (self-regulating) alternators. These machines will supply current to 51 arcs of 2,000 c.p. on wrought-iron poles, and six portable arcs to be used in loading and unloading operations, also 800 incandescents of 16 c.p. distributed in the various offices and storerooms. The latter are run from transformers. The mains are underground, principally run through subways, which already exist for the hydraulic mains. Some 30 miles altogether of okonite-covered wire will be used, about half of this being wanted for external work and the remaining half for internal work. We shall have to refer to the details of this installation in further issues, and trust that it will be the forerunner of much similar work in India and our colonies.

ON THE THEORY OF COMPOUND WINDING FOR CONSTANT POTENTIAL.*

BY DR. LOUIS BELL.

I wish to preface this paper by stating that there is in it nothing revolutionary, nor any radically novel attempt to treat a problem that has already been handled by more skilful hands than mine. It is simply an effort to bring the theory of compound winding to a practical basis, indulging in no complicated formulæ, and introducing no constants that cannot be conveniently determined in practice. To this end I shall consider the subject synthetically rather than analytically, starting from the plain shunt winding, and considering those terms which must be introduced to take account of the failure of shunt winding to give constant potential. I do not think that compound winding should be considered as anything more than a method of improving a shunt machine already well designed; it should certainly never be called upon to avoid the evil effects of bad design.

For the systematic treatment of the subject I would introduce the following notation, which differs slightly from that most often employed, but is convenient for the purpose in hand.

Let C_x, represent the current on the line;
C_s, the current in the shunt coils;
R, the resistance of shunt coils;
r, the resistance of armature and series coil combined;
E, the E.M.F. of the machine running light;
e, the fall of potential due to armature resistance;
N, the number of convolutions in shunt coils;
n, the number of convolutions in series coils;
m, the number of convolutions on armature;
a, b, c, the three terms of n;
l, the angle of lead;
q, the magnetic resistance of machine on open circuit;
q_x, the magnetic resistance of machine at full load; and
p, the value of q_x divided by q.

I shall consider especially the long shunt arrangement, though, as will be seen later, the short shunt leads to practically the same results.

The first and obvious cause of fall of potential at the terminals of the machine is due to the fact that the armature has a resistance; as the current increases a certain amount of potential is absorbed in the armature, and consequently the available E.M.F. at the terminals fall. The amount of decrease is evidently proportional to the resistance in the armature and the current through it.

$$e = r\,C_x.$$

To compensate this loss we must furnish an increase of induction sufficient to produce e additional E.M.F. If the field magnets and the armature core were quite unsaturated—that is, if we could neglect the change in permeability—we should simply increase the total ampere-turns to an amount sufficient to compensate the fall in potential. Let a be the series turns capable of producing this at full load, neglecting change in permeability, then

$$a = \frac{\mathrm{N}\,r}{\mathrm{R}}.$$

But the permeability decreases as we put on this additional induction. The magnetic resistance, q, at the start, will have increased to a certain other value, q_x. We must therefore increase the number of series turns to take account of this added resistance, and we have

$$a = \frac{\mathrm{N}\,r}{\mathrm{R}}\,p.$$

It will be observed that this quantity does not have to be multiplied by the coefficient of leakage because we have simply reduced the shunt turns to equivalent series turns, and consequently have already included it. This formula will be at once recognised as practically equivalent to that given by Thompson in his well-known book, and at this point Thompson drops the investigation, merely mentioning incidentally some of the other causes which necessitate compounding. Thompson's formula:

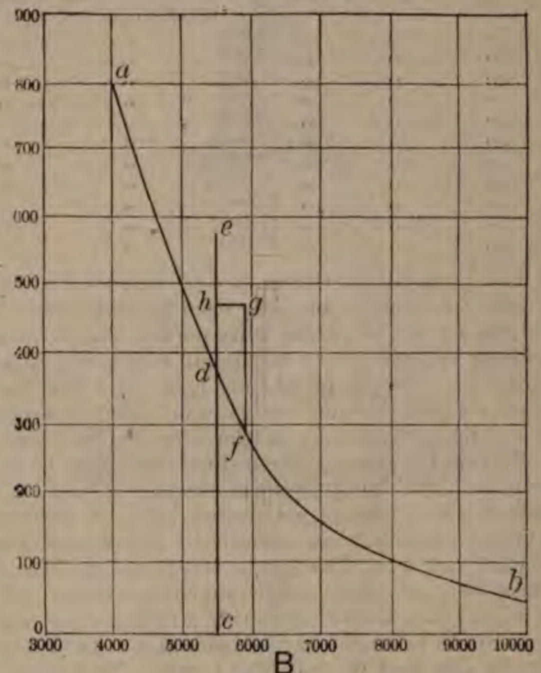


FIG. 1.

$$\frac{\mathrm{Z}}{\mathrm{S}} = \frac{r_s}{r_s + r_m} \times \frac{q_1}{q_0}$$

is not quite the same as mine, for the reason that while his q_0 is proportional to the permeability when there is no external current, his q_1 is proportional not to the permeability at maximum current, but to the mean permeability between no load and full load. Hence, if Z is taken as the number of shunt turns required to give the desired potential on open circuit, Thompson's formula will inevitably give too few series turns for the reason just mentioned, if for no other. But since by adding series turns the magnetic resistance is increased, the shunt winding which produces E volts on open circuit will not do so at full load. Additional series turns must then be employed to compensate for this, and since the change in shunt ampere-turns must be from N C to N C p, the number of series turns to be added to compensate for the decreased effect of the shunt will be

$$b = \frac{\mathrm{N\,E}}{\mathrm{R}}\,(p - 1).$$

---

* A paper read before the American Institute of Electrical Engineers, New York, November 18th, 1890.

This term also includes C_x co-efficient of leakage for the same reason as before.

It will be noticed that both A and B include the quantity p, and here is met the principal difficulty in effecting the compounding. It is my purpose to show that this quantity p can be obtained from known data with sufficient accuracy for the purpose in hand. It will evidently be a quantity little in excess of unity, and in practical machines may range from 1·05 to 1·50, although in certain cases it may even exceed the latter figure. Thompson gives the case of a certain Siemens compound machine in which p would be over three. This, however, must have had a very insufficient amount of iron in the magnets or the armature core, or both. We fortunately do not have to deal with dynamos of such bad design very frequently. Provided we have known enough about the iron to be used in a given machine to design the shunt winding intelligently, we shall also know enough to design the compound winding. If we have at hand the characteristic curve of a similar shunt machine p can be determined very easily from it. I give herewith the data for the Manchester machine described by Dr. Hopkinson. I have simply taken the apparent permeability from his characteristic curve.

When magnetising force equals		$\frac{\text{induction}}{\text{magnetising force.}}$	equals

,, ,, ,,	12,000	,,	,,	333

If the permeabilty curve of the iron is known even approximately we can obtain p from it quite readily. In Fig. 1, let $a\,b$ be the permeability curve. The permeability at no load corresponds to the point d, that at full load to the point f. Now lay off the ordinate $d\,e$ so that the ratio between $d\,e$ and $c\,d$ equals the ratio between the iron resistance and the air resistance of the proposed machine, then lay off from the point f the ordinate $f\,g$, equal to $d\,e$, and draw $g\,h$. Then the ratio of the lengths, $h\,c$ and $e\,c$, corresponds to the quantity p required. Fig. 2, drawn from Hopkinson's figures, gives numerically the change in permeability for cast iron. The figures relating to the Manchester machine were, of course, for wrought-iron cores and cast-iron poles. It is thus evident that a rather close approximation to the value of p can be made if we know anything about the iron that we are going to use. Now, as we shall see later, and as is, indeed, evident at the start, a and b are of about the same order of magnitude. I do not think that b will ever be negligible in a practical machine unless a is also negligible, and there is, therefore, little need for compounding. When the magnets are anyway near saturation b will be much larger than a, but both a and b combined will not give the proper number of series turns for constant potential unless the armature is run with no load, and therefore produces no demagnetising effect. The approximate demagnetising effect of the armature has been investigated by Hopkinson and is as follows:

$$4\,n\,C\frac{m}{2} \times \frac{2l}{\pi} = 4\,l\,m\,C.$$

In other words, it is due to the convolutions included in twice the angle of lead. For constant potential we must add then c turns in series equal

$$v\,m\frac{l}{\pi}.$$

It is evident at once that a change in lead will affect the compounding; an increased load will cause the machine to under-compound; a decreased load to over-compound. As, however, the amount of distortion in the field depends largely on the shape of the extremities of the pole-pieces, the above uncertain factor in compounding can often be gotten rid of by a little care in designing the poles.

It is obvious that the term c is to include the coefficient of leakage. Uniting now, the three terms, a, b and c, we have finally, as the completed formula for compound winding, the following:

$$n = p\frac{N\,r}{R} + \frac{\frac{N\,E}{R}(p-1)}{C\,x} + v\,m\frac{l}{\pi}$$

It now may be interesting to see how well this formula applies to practical machines. I regret to say that I have been unable to get full details of any machine which gave exact compounding, but I have obtained an assortment sufficiently large to show in a general way the applications of the formula.

Machine No. 1, 110 volts, 8 amperes, over-compounded 2 volts. For this small machine take p equal to 1·2. Applying the formula, a equal 14, b equals 44, c equals 15; total series turns by formula, 73; actual number, 90.

Machine No. 2, 110 volts, 3 amperes, over-compounded 3 to 5 volts. a equals 2, b equals 7, c equals 7; total series turns by formula, 16; actual number, 28.

Machine No. 3, 500 volts, 20 amperes. p equal to 1·1, a equals 3, b equals 15, c equals 14; total turns by formula, 33; actual number, 60. Machine over-compounded 3 to 5 volts.

Machine No. 4, 110 volts, 200 amperes, over-compounded 5 volts. p equals 1·05; lead rather large. a equals 2, b equals 2, c equals 5; total turns required, 9; actual number, 12.

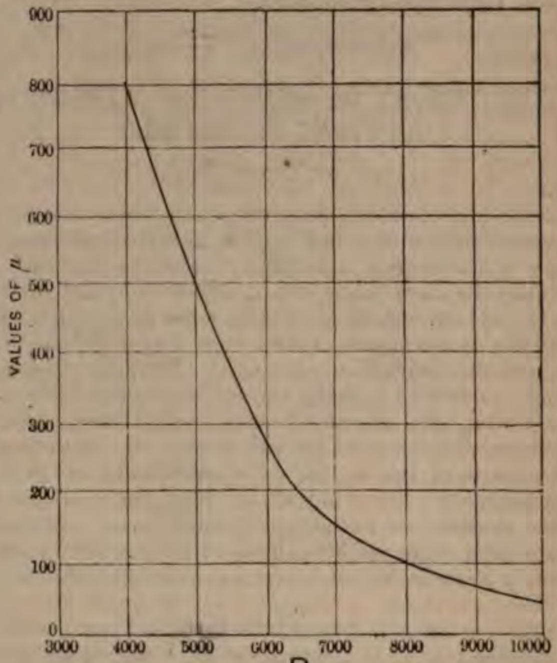

Fig. 2.

Machine No. 5, 500 volts, 60 amperes. p equals 1·05, over-compounded about 7 per cent. a equals 3, b equals 5, c equals 4; total, 12; actual number, 32.

Machine No. 6, 500 volts, 90 amperes. p equals 1·05; a equals 3, b equals 4, c equals 4; total turns should be 11; actual number, 19. Machine over-compounded like the former.

Machine No. 7, 500 volts, 150 amperes. p equals 1·05; over-compounded 7 per cent. a equals 3, b equals 3, c equals 3; total 9; actual number of turns, 28.

Machine No. 8, 100 volts, 30 amperes. p equals 1·1, a equals 13, b equals 46, c equals 25; total 84; actual turns, 56. Machine over-compounded about 2 volts, and the shunt winding did not bring the potential up to the 100 volts intended

These are merely rough figures, obtained without the use of even the permeability curve of the iron—simply by estimation from permeability curves at hand. It will be seen, however, that all the over-compounded machines got from the formula too few series turns, while the under-compounded machines gave too many. I think that the discrepancy is of about the right order of magnitude, although we cannot verify it accurately without the curve of the iron.

It remains to consider some few further points regarding compounding. If the winding is designed to give the potential at practically no load and at full load, it necessarily follows that at some point between the potential will rise; for, while the magnetising force changes along a line, the magnetic resistance changes along the corresponding curve between the same points.

An approximate idea of the amount of irregularity in potential may be gained from Fig. 1. Connect in this diagram *d* and *f* by a straight line. From its middle point drop an ordinate upon the axis. The length intercepted between the straight line and the permeability curve then gives the error in compounding by comparison with the total change of magnetic resistance.

It should be noted that the formula I have given determines the compound winding for a given assumed potential produced by the shunt coil alone; therefore, if the machine is to be run at a slightly different speed from that at first intended to produce this given voltage, the compounding is still correct, for it pertains to the voltage rather than to the speed. If the speed of a correctly compounded machine be raised and the current in the shunt kept constant, it will tend to over-compound. If the current in the shunt is allowed to increase, the change in resistance will decrease the relative power of the series coils, and the machine will under-compound.

It now only remains to glance at some of the formulæ heretofore given. That of Thompson I have already incidentally discussed. That of Frölich (perhaps the best we have had) should receive mention here. Frölich takes account of the change in the permeability by introducing a quantity *f*. Like Thompson, his formulæ involve two points of saturation. It should be said here that there is no special black magic about the half saturation point of a dynamo, any more than about the $\frac{3}{7}$ths or the $\frac{7}{13}$ths saturation point. In very many cases it happens to be about the point at which the machine is used. Kapp, in his well-known and excellent book, takes account of the change in permeability with a fair degree of approximation, by the use of his tangent function. All these attempts at the proper theory of compounding depend, like the one which I have just presented, on forming some sort of an estimate on the change in magnetic resistance of a dynamo, due to adding a certain amount of induction. Without some approximate method of finding this quantity, the problem is indeterminate, and the special thing which I have endeavoured to show is that from the data already at hand about iron we can form a sufficiently close estimate of the value of the coefficient *p* without either knowing the characteristic of the machine or indulging in endless approximations. I hope that some practical designer will look into the values that *p* takes in his machines, and I believe that it can be readily enough obtained to permit of quite accurate compounding by the use of the formula I have given. The introduction of the terms *b* and *c* I regard as important. Their existence has been well known, but I do not think they have received the attention that I have endeavoured to show they deserve.

ELECTRICAL ACCESSORIES.

While the details of dynamos and of underground mains are being perfected and brought up to date, makers of the interior fittings and accessories are not behindhand. A considerable number of very handy, ingenious, and handsome fittings for inside housework on electric installations have just been brought out by the Electrical Accessories Company, and illustrations of some of the most interesting of these are given herewith.

Several neat and inexpensive brackets are fitted with a recently patented universal globe carrier. One of these fittings is shown in Fig. 1, and they are made with several other patterns of bracket with glass shade or globe as Fig. 2, or also for pendants, as in Fig. 3. The fixing and removal of shades and globes for cleaning is greatly facilitated by the use of this carrier, and it is constructed to add to rather than detract from the appearance of the fitting. Various ornamental designs are made, and they are arranged to suit the fittings and lampholders most generally used. The illustrations show them as adapted both for globes and shades. In these patterns they screw on to the lampholder instead of the ring carrier; in other forms the lampholder itself screws upon a nozzle inside the carrier. The small carrier, Fig. 2, is for shades with small openings, $1\frac{1}{8}$in. to $1\frac{1}{4}$in. diameter; the larger size, Fig. 2, is for globes or pines of $2\frac{3}{4}$in. to 3in. opening. Similar sizes with claws reversed are made, suitable for flanged globes, It is pointed out, however, that one of the claims

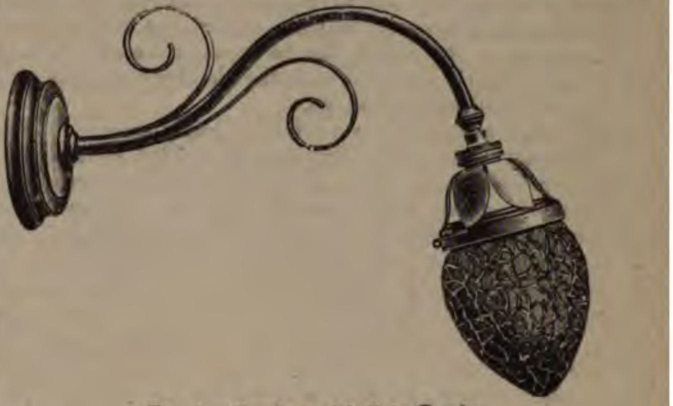

Fig. 1.—Bracket with Grip Carrier.

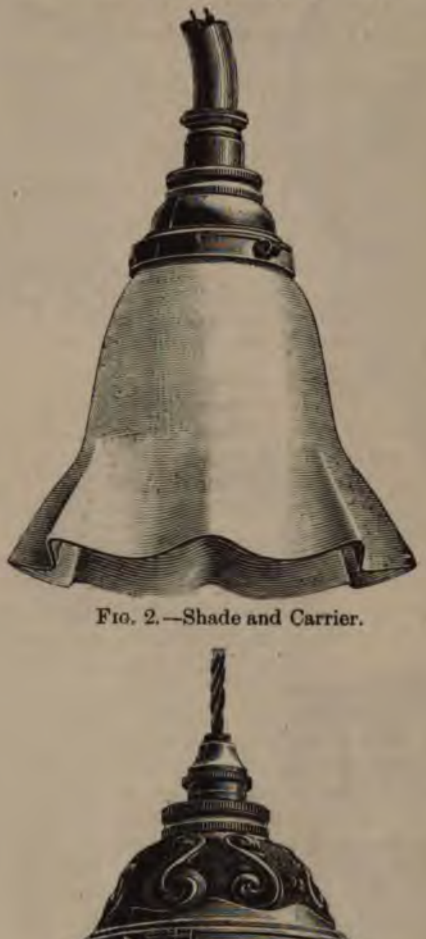

Fig. 2.—Shade and Carrier.

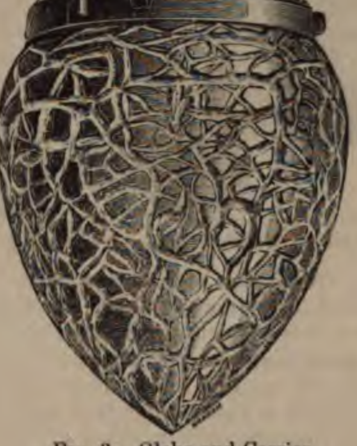

Fig. 3.—Globe and Carrier.

in favour of this carrier is that the flange on the glass is no longer necessary, and thus the cost of the globe itself is reduced, while the appearance is improved.

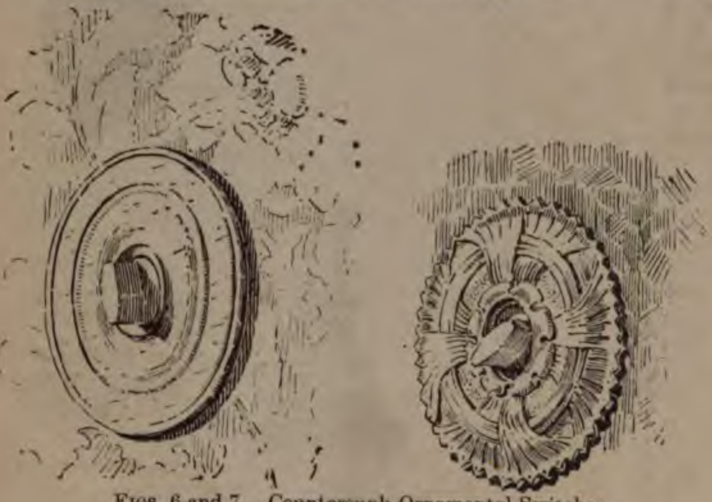
A considerable number of these carriers is now in use, and, as bearing upon the saving in labour for attendance and cleaning, it is stated that in practice the removal and replacement of the shades can be accomplished in one-fifth the time formerly required with the old screw carriers, and with less likelihood of leakage.

The inner action of this carrier is clearly shown in Fig. 4. The flat brass triple eccentric is guided centrally by three pins working in slots; the three claws are carried by slides working over the eccentric ring, the cam action of which causes the claws to advance or recede together.

approval of the fire insurance authorities. It is a switch which deserves and will doubtless receive a large success.

Some particular attention has been given to what are known as countersunk switches, those let flush into the wall with the thumb-piece only protruding. Specimens of these are shown in Figs. 6 and 7. In many, especially high-class installations, this style of switch is preferred, as better harmonising with the surrounding decoration. In the countersunk switch the working part is sunk in a box suitably constructed to prevent the penetration of moisture, while the cover is of chased brass of a variety of ornamental patterns, or may be bronzed or plated or made of wood as best may suit the surroundings or the taste of the owner.

The main spring contact switches illustrated are of a new pattern on Drake and Gorham's patent, an improvement on the well-known "ring contact" switches patented by the same firm some years ago. The advantages and simplicity, as well as the solidity of the construction, are apparent from the illustrations, Fig. 8 and 9. It will be seen that the circuit is completed by U-shaped strip from one terminal to the other. This is a special feature of the design, and its advantages include lower cost of construction, less space required, and the avoidance of any possibility of heating. The tension at the contacts is regulated by the distance pins between the arms. A flat steel spring is fitted to the base to keep the bar in its extreme



FIGS. 6 and 7.—Countersunk Ornamental Switches.

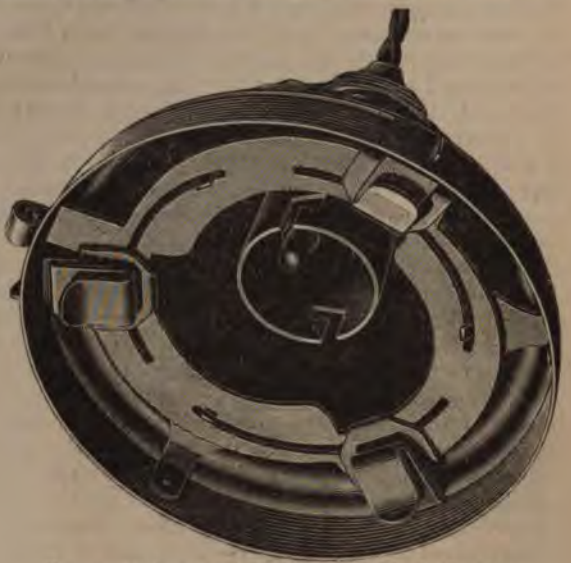


FIG 4.—"Accessories" Universal Shade Carrier.

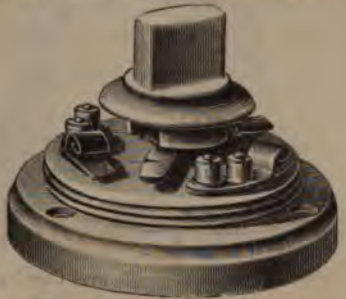

FIG. 5.—Porcelain Switch.

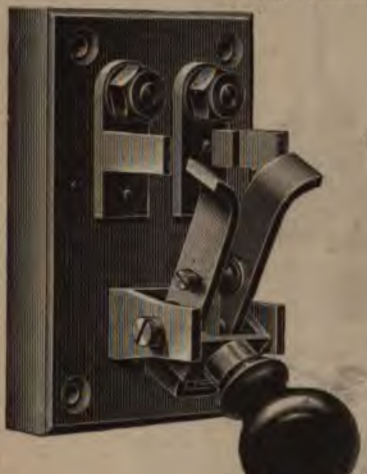

FIG. 8.—Spring Contact Switch.

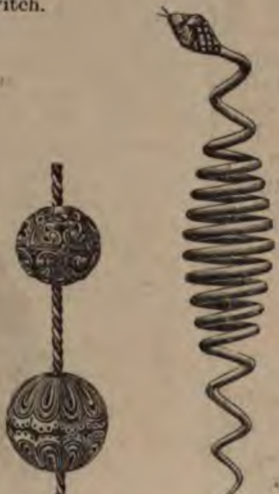

FIGS. 15 and 16.—Cord Ornaments.

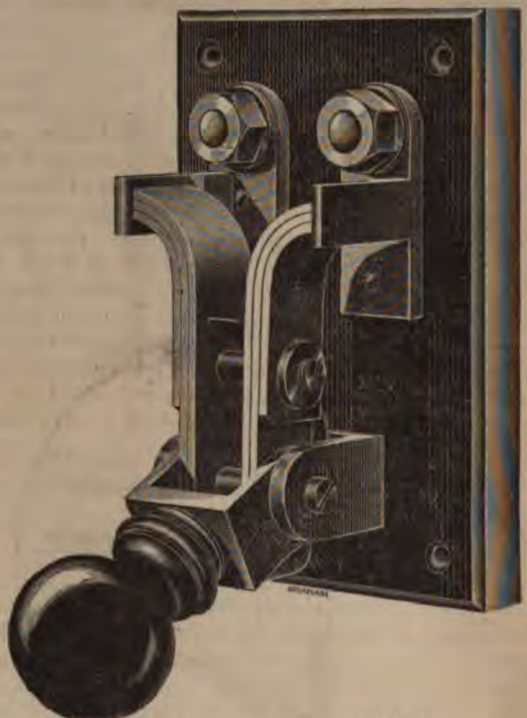

FIG. 9.—Main Spring Contact Switch.

In switches, a very neat and simple pattern, Fig. 5, has been brought out, combining in itself those good qualities which are absolutely requisite for a successful room switch. They have a porcelain base, and are made with an instantaneous break (under the well known Holmes's master patent); the circuit is from contact to contact across a solid bridge piece and not through working points. There is a double break of considerable distance, and space for a long fuse, while all the parts are most simple in construction. The question of easy fixing and other considerations from the contractor's point of view have been given special attention, and the construction has met with the full "off" position when the circuit is open. The switch may accordingly be fixed horizontally or with the handle at the top of such positions are more convenient.

A set of these switches, with suitable fuses fitted on a slate base, and provided with glass doors, Fig. 10, form a very useful main distributing switch-box.

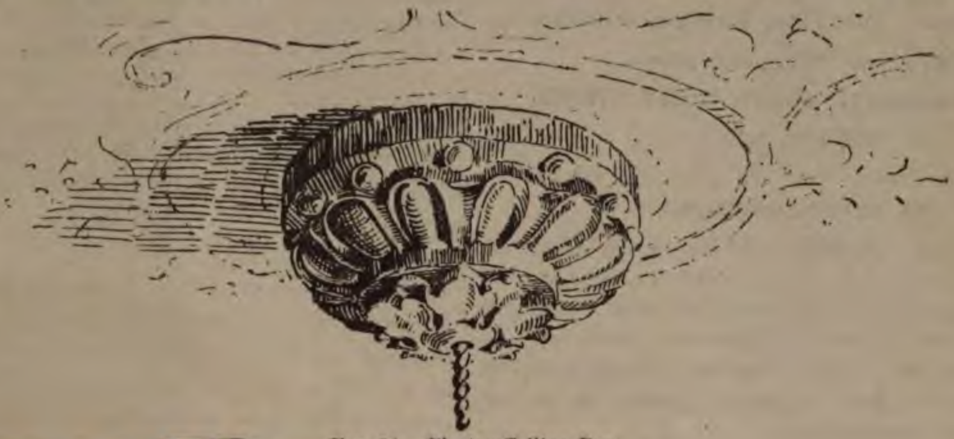

Fig. 14.—Plaster Ceiling Rose.

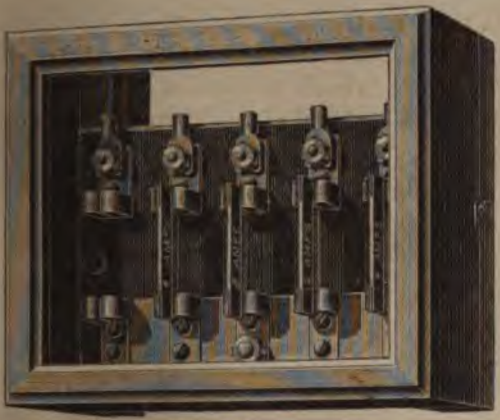

Fig. 11.—Branchway Fuse-box.

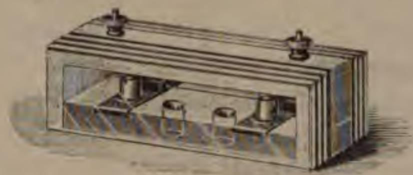

Fig. 12.—Casing Pattern Glass Fuse.

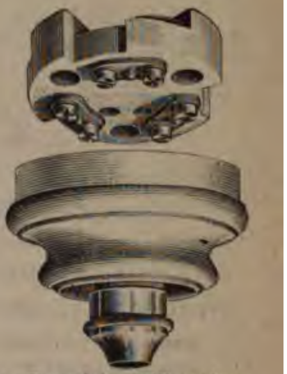

Fig. 13.—Porcelain Ceiling Rose with Cord Grip.

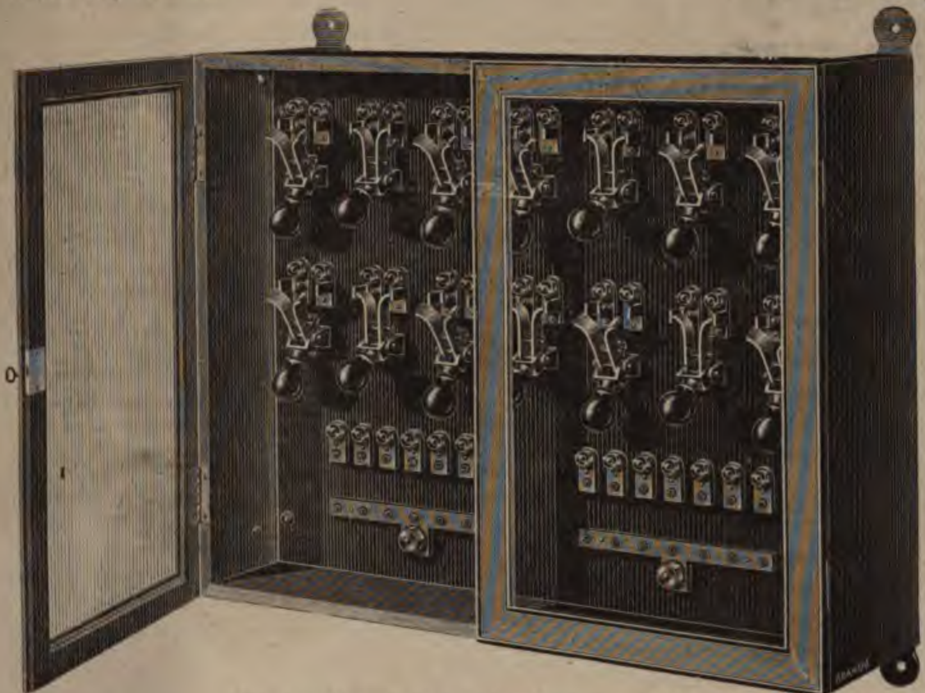

Fig. 10.—Distributing Spring Contact Switchboard.

A very useful form of fuse-box, with branchway fuses, for distribution on the various floors of a building from one source is shown in Fig. 11. We have already mentioned this type of fuse-box in connection with the installation at Madame Tussaud's, where they were first employed, and the form as now manufactured in box with glass cover embodies a highly-desirable method of wiring. The illustration explains itself—the "bridge" type of fuse, with the amount of current carried plainly marked thereon, can be readily slipped into place by an ordinary attendant, without the necessity for unscrewing and without fear of shocks or derangement of the other circuits. A neat little fuse case for single fuses, with glass sides and a cover in porcelain to imitate the ordinary casing, is shown in Fig. 12. The same type of "bridge" fuse, carrying up to five amperes, is used in this.

Amongst the other little "accessories" of which the Electrical Accessories Company make a speciality are wall sockets and ceiling roses. A new type of the ceiling rose is shown in Fig. 13, which illustrates a simple and efficient method of obtaining an easy fixture for the cover. The ceiling roses are fitted with a cord grip to bind the flexible cord, so as to take the pendant weight from off the terminals. They are made with either porcelain or wood covers. Fig. 14 shows an artistic adaptation to a plaster ceiling rose for a moulded ceiling of a drawing-room. Figs. 15 and 16 illustrate some little ornaments to attach lower down on the pendant cords.

BOUND VOLUMES.

Vols. I. to VI. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

We may occasionally follow the lead of our American Contemporaries, especially when they point out a serviceable way. They are not backward in asking their friends to do all they can for the welfare of the paper. We ask our friends to remember us. No Paper that we know ever refuses Subscribers or Advertisers. Nor do we; in fact, we invite them, believing that they will get full value for their money.

Specimen copies of the paper will be sent on request.

1891.

The year 1890 has not been productive of any great discovery in connection with dynamo-electric machines, or of any marked change in the method of applying previously known principles; but it has, nevertheless, been a year in which steady though slow progress has been made. This progress has been mainly in two directions—viz., the construction of more efficient large output machines, and the improvement and simplification of details.

The current of public opinion which set in so strongly a year or two ago in favour of alternate currents and high-potential systems of distribution appears, for a time, to have run its course, and just at present direct currents and low-potential systems of distribution receive more general favourable consideration. This being so, we must look to direct-current machines for most of the improvements of the year. We find that most of the large makers appear to be assimilating their types more and more to a uniform pattern. The single horseshoe form of magnet and the cylinder Gramme shape of armature now seems most in favour.

The demand for machines for electric power stations has not fulfilled anticipations, though the City and South London Railway just opened will, it is hoped, prove the first of a number of similar undertakings.

The great attention which has been paid to details in the making of the dynamos has resulted in the production of some first-class articles—machines one can not only admire, but depend upon.

In brush-holders the improvement is very marked, the simplicity and ease of handling of new ones contrasts very favourably with the clumsy appendages so named a few years ago. Though the wire gauze brush is gradually being more used, it is not superseding the old-fashioned straight wire one as rapidly as its early advocates prophesied.

The number of large output machines which have been built during the year is without parallel in the history of the industry in this country, and much work has been done in devising methods of overcoming the special difficulties met with in constructing them.

We have not heard much of the Fritsche disc machine, from which, or from some improved adaptation, we were led to expect great things; perhaps this is what 1891 will bring us.

The most notable contributions to dynamo literature during the year have been the two papers read at the Institution of Electrical Engineers—viz., "The Theory of Armature Reactions in Dynamos and Motors" by Mr. Swinburne, and "Some Points in Dynamo and Motor Design" by Mr. Esson, for which he has been awarded the Institution premium for the year. These papers, read immediately following one another and discussed together, form with the discussion a most valuable addition to our knowledge of the reactions which go on in large dynamo machines. In his paper Mr. Swinburne gave the results of two or three years' work in designing large dynamos. As the output, and consequently the current flowing through the armature, increases, it follows that the armature becomes magnetised through a larger range than when only small currents are used. Hence the effects of cross magnetisation become more marked, and the difficulty of sparking at the brushes is much increased. He advocated the use of small subsidiary magnets excited by means of the main current, and placed so as to neutralise the effect of the magnetisation caused in the armature. These, however, up to the present have not come into general use. Mr. Esson dwelt upon the necessity in designing a dynamo of having a symmetrical field through the armature, so as to ensure good electrical and magnetic balance, and noticed some of the devices used by various makers to counteract the magnetic pull on the armature in machines which have a single magnetic circuit. Passing on to the question of the maximum safe output to be continually got from dynamos, he gave for ring armatures a formula which he had used for some years with good results, and then went on to treat of the subject of the rise of temperature which could safely be allowed to take place in a machine while working. During the discussion which followed considerable differences of opinion were shown to exist among designers on this point. Many condemned the Admiralty limits of 14deg. C. after six hours' continuous running as being too rigid; and advocated such high allowable temperatures as 30deg. and 35deg. C. above surrounding temperature, or not more than 70deg. or 75deg. C. altogether.

These are a few of the chief facts which another year's experience in dynamo work has brought to us. There are yet many improvements—mainly in small details—necessary, which will eventually make the dynamo as reliable to work as it is economical to use.

It cannot be expected that any great improvement can be made in the construction of dynamos, especially if, as Mr. Crompton claims, they are now constructed to give 96 per cent. commercial efficiency. This is almost perfection so far as the electrical conditions go, and the only question to be asked is, whether such perfect electrical machines are good mechanical machines. It seems certain, however, that the mechanical arrangement must be almost or quite as good as the electrical, otherwise the efficiency could not be so large. With a perfectly balanced machine, then, of so great efficiency little room is left for improvement one way or the other.

FUTURE PROSPECTS.—In our request for information about the past year's work, among other questions we asked for an expression of opinion as to the future prospects. Without exception, all who have replied have given a favourable opinion. Everyone seems to think that the amount of work must progress. Many consider that progression will be by leaps and bounds, the only limiting quantity being workmanship. Many hold that the bright prospect will largely increase the numbers occupied in the industry, and lead to competition of so keen a character that prices will be unduly lowered. No doubt this is a danger, but it is even now somewhat difficult to understand how some firms can take contracts at the prices of their tenders. This point becomes still more difficult to understand when we find middlemen competing successfully against makers. We have been led to believe that prices for dynamos are too low now, and yet the middleman, who has to buy everything of the makers, can and does take work that makers compete for. Of course the reply to this is obvious, that the cost of the dynamos in a large installation is but a fraction of the whole cost, and if makers charge more for the other part of the work than the middleman, the latter must get the whole work, despite the competitors being makers. If this is so, makers must look to their charges for the other parts of the installation work, and not look to the being makers of machines to give them the advantage.

LOCAL AUTHORITIES v. SUPPLY COMPANIES.—Other questions upon which we solicited information related to the position of local authorities as against supply companies. Opinions upon these questions differ, some being emphatically in favour of supply companies. Others are not so strong in their objections to local authorities, but we must confess to a real surprise that not one was entirely in favour of local authorities. The general view seems to be that even when a local authority takes action, it is more often with a view to procrastination, and not with any real intention of doing work. This is surprising in that some local authorities, at any rate, have taken action. Witness work done at Taunton, Bath, Bradford, the work to be done at Barnsley, Northampton, Bournemouth, Brighton, Dublin, etc. We cannot expect a large percentage to move in these early days, and it really seems that the percentage who mean work is quite as large as could possibly be expected. However, the local authorities evidently do not find much favour in the eyes of electrical engineers. The following extract perhaps gives the most favourable opinion so far as local authorities are concerned:

"There is a great deal to be said on both sides. The principal objection to local authorities doing business is they are apt to perpetrate jobs. Some loud-voiced councillor names his friend whom he knows can do the work well. The loud-voiced councillor's friends support him, as he will do the same for them on another occasion; the loud man's friend gets the contract and is duly grateful. On the other hand, though if work done by public bodies is generally very expensively done, it is in the majority of cases well done, and that is entirely to the advantage of the advance of electricity. If a corrupt councillor is able to make his constituents pay more than they need do, the engineers on whom devolve the actual seeing the work carried out are usually on their mettle, and will have it well done. Where private companies undertake the work there is too often a strong temptation to do it too cheaply in order to make dividends. Private companies are too ready to compete with gas, often at a ruinous price, and then try to pay a dividend by doing the work cheaply. Later on the light fails, and the era of progress is stayed for a time. Our very best card is good work, no matter by whom it is done. Bad work injures everyone."

POWER IN NEW ZEALAND.—Although, as has been stated, power distribution does not make that rapid progress which was hoped for, installations here and there are carried out with success. The number of such installations must increase, and especially will this be the case where water power is available. In our colonies there are many sites admirably adapted for the utilisation of such water power, and we are glad to see signs of appreciation of electric transmission. About a year ago, Mr. Postlethwaite, the agent for the Electrical Engineering Corporation, put up a power installation at the Temuka flax mills, and from the time the current was first switched on up to the present the entire plant has worked with the most perfect success, and without a single hitch of any kind whatever. The dynamo is a mile away from the motor. It is stated that a great saving has been effected in thus substituting electricity for steam. For some time the machinery has been running night and day, and the cost of attending to the dynamo and motor has amounted to just 6s. per week, this being the amount allowed to the man in charge of the mill to visit the dynamo-house twice in every 24 hours for the purpose of switching on or off. The attendance on a steam engine would cost more than this. But of course water power is not everywhere available.

Another departure in the transmission of power of a unique character has been in actuating Wolseley sheep-shearing machines by motors. This has been carried out on Mr. W. Postlethwaite's Raukapuka estate, where 10 of these machines were electrically worked, and it is calculated that the extra value of the clip of 13,000 sheep has nearly recouped in one season the whole cost of putting up the machines. At Raukapuka a turbine drives a Statter dynamo. An overhead wire conducts the current to the motor which drives the shafting in the woolshed. Special arrangements are made to keep the speed of the shafting constant, though the work being done continually varies. The house at Raukapuka is lighted by electricity, and this agent is used in various ways.

GENERAL ELECTRIC POWER AND TRACTION COMPANY.—About the middle of this year the business of Messrs. Immisch and Co. was amalgamated with that of the Electric Traction Company; the two firms now trade under the title of the General Electric Power and Traction Company, Limited. The new company have primarily for their main object electric traction and general power work; but they in no wise confine themselves to these branches, and have, during the past year, accomplished a considerable amount of lighting and general work. Their business may be roughly divided into four branches—viz., 1, mining work; 2, tramcar work; 3, electric launch work; 4, general work. Work in the mining department has been exceptionally brisk, and installations have been erected in England, Wales, Scotland, the Continent, Asia, Africa, and Australia. Without going into details it may be mentioned that almost the whole range of mining work has been successfully accomplished by the Immisch plants; winding, hauling, pumping, fan-driving, rock-drilling, etc., having been carried out in different pits, and in nearly all cases the plants have been arranged on the compound parallel system so as to be adapted for both lighting and power. The aggregate horse-power supplied during 1890 in dynamos and motors for this purpose is very nearly 1,000 h.p. In tramcar work, although no new lines have been laid down in the past year by the company, they have made considerable progress in the general details of accumulator work, and have successfully run their cars on the North Metropolitan Tramway Company's lines at Barking during the whole of the year. The total mileage for the year is approximately 80,000 car miles. According to schedule time the possible mileage was approximately 1 per cent. more than that actually run. The experience thus gained has enabled the directors to undertake the maintenance of electrically-equipped accumulator car lines at rates which will compare favourably with horses. The company is prepared to treat with tramway companies on these conditions, and have now in course of preparation estimates for several important lines. With regard to electric launch work, during the past summer the company had launches both on the Thames and on the Union Canal at Edinburgh, during the late exhibition. The number of passengers carried at Edinburgh was about 100,000, and the result commercially was thoroughly satisfactory. On the Thames some 12 launches were kept for hire, and although the season was a bad one, yet they were patronised by the public to a large extent. Many important improvements in motors, switches, and propellers have been introduced by the company, and in the coming season it is expected that a very considerable increase will be made in the number of boats plying for hire, and consequently in the financial returns of this department. The general work of the company during 1890 was far in excess of that of the previous year, and shows a large increase in the demand for motors suitable for central stations, and motors for special machine tools have been in fair demand. A large number of dynamos for electric lighting have also been supplied by the company, and several important installations have been carried out. Amongst others may be mentioned Tatton Hall, Knutsford, the residence of Lord Egerton of Tatton. The prospect for 1891 is decidedly good, and the company starts the New Year with a large number of contracts in hand. Several important mining plants are now in course of erection, and others are in negotiation. Electric traction is undoubtedly coming well forward, and the next 12 months will see several schemes brought to a successful issue.

HENLEY'S TELEGRAPH WORKS.—The business of this company for the past year has been very good, and considerably greater than 1889. In the early summer they successfully laid the cable between Halifax (U.S.) and the Bermudas (850 nautical miles), and have since constructed 1,021 nautical miles of cable for the West Indies and South America, the laying of which has just been satisfactorily completed. The company has altogether had a very successful year in its submarine cable department, other cables made in addition to those referred to above being the cable for connecting the Island of Anticosti, in the Gulf of St. Lawrence, with the mainland, for the Canadian Government; a new cable between Nyborg and Korsor, in the Baltic, and various small cables for home and abroad. In the manufacture of vulcanised indiarubber electric light mains and cables, and wires for house wiring, the company has been exceedingly busy. Most of the London and provincial supply companies are buyers of Henley's vulcanised indiarubber mains. The company has just opened a stockroom to meet the requirements of their customers at 27, Martin's-lane, Cannon-street, for immediate delivery of any standard sizes of wires and cables.

TELEGRAPH MANUFACTURING COMPANY. — The works of this company have been extremely busy during the past 12 months and all departments have been fully employed. The guttapercha wire made by this company has been in such demand, that although the plant has been doubled, the supply has scarcely been able to keep pace with orders. It has been found necessary to erect new buildings for the battery and insulator departments in order to cope with the work, and also to take large premises in Liverpool for the instrument department. All these will be in working order in a few weeks, and then the whole extensive Helsby Works will be solely devoted to the manufacture of electric light, telephone, and telegraph wires and cables, and very shortly the company will be in a position to more than double their already large output.

SYDNEY F. WALKER AND CO. cannot show a very large record of new work during the past year, not so large as they would like, owing to the keen competition which has prevailed. There has been plenty of work, but plenty of people to do it. During the summer this firm laid down a 400-light plant for a large coal and iron firm in Lancashire. As rather a new departure was made in this case the details may be interesting. The installation consists of two complete and independent plants, each capable of furnishing 200 lamps or their equivalent. Separate engines and dynamos are used, not connected in any way; and the whole is so arranged by means of specially designed switches, on Mr. Walker's bent spring principle, that either engine and dynamo can be switched on to any part of the work at will. When the full output of the plant is taken up, one dynamo and engine will work the surface lights and the other the underground lights, but at present one dynamo runs all the lights that are required for 24 or 48 hours, then the other is run, and so on. In Mr. Walker's opinion this is the plan upon which installations should be put down, as it gives so many more chances against a breakdown. Later in the year they put in another installation for the same firm, consisting of a 100-light plant. In both cases incandescent lamps of 16 c.p., 50 c.p., 100 and 200 c.p. are used, showing the wonderful adaptability of the incandescent system with the compound dynamo. This firm has also fitted up another colliery in Lancashire with a 100-light plant. They have had their usual mining work as in past years, and in addition have done a good deal of wiring and fitting up in connection with the Newcastle supply companies, and in other towns. An important piece of work that was undertaken and successfully carried through was the construction of a 3,000-ampere switch for use in connection with some experiments that were being made for the production of aluminium by the aid of the electric current. The slate base alone weighed over a hundredweight, and the details involved were more like those met with in engine-building than in switch-making. During the year they have considerably modified the construction of their dynamos in order to keep pace with the advancing knowledge on the part of users. To meet immediate requirements, they have made a dynamo on the old lines, but with a bobbin very much elongated, the machine itself being the same length as before, and the bearings being quite outside the frame of the machine. So far, this dynamo has run remarkably well. Mr. Walker's views up till recently were that it was unwise to depart from the old type first introduced by Gramme, except to add iron, and thereby increase the efficiency; as it was of more importance for a dynamo to be very simple than to save a few tons of coal in the year. Recently, however, he has found so large an increase in the knowledge of the subject among users, that his firm have been induced to join in the general procession of dynamo makers; and he has designed a single horseshoe dynamo—something on Mr. Kapp's lines—in which he claims to have included all modern improvements that are suitable for his work, and that are open. It is named "The Patriarch."

WEEMS'S SYSTEM.—In America and elsewhere the pithy descriptions that have been given of the Weems railway system, led us to enquire what the prospects of this system are. Mr. Weems, in reply to our enquiries, says: "We have every indication of making a most splendid success in our rapid transit in this particular line, and propose at no very distant day to convey passengers and mails at a speed of 120 miles per hour with perfect safety and convenience."

"It does not require a very vivid imagination to appreciate what a revolution will then be made in railroad traffic throughout the entire world."

If Mr. Weems's supposition is correct we shall hail with pleasure a practical exemplification of his scheme.

WOODHOUSE AND RAWSON.—The year ending 31st December, 1890, shows very rapid strides and developments in the well-known undertaking of Messrs. Woodhouse and Rawson United, Limited, one of the most enterprising and progressive of the electrical firms. The company in the beginning of the year removed their head offices from 11, Queen Victoria-street, to very extensive premises having frontages to 30, Cannon-street, and 88, Queen Victoria-street respectively, but notwithstanding the size of the new premises to meet the requirements of their increasing business, the company have been obliged to take the whole of an adjoining block of buildings forming the apex of the triangle facing Mansion House Station, leading to Cannon-street on the right hand, and Queen Victoria-street on the left. The new showrooms will be at 34, Cannon-street, and the secretary's office at 88, Queen Victoria-street. Among the leading developments of the business may be mentioned the purchase and working of the large engineering works at Kidsgrove, near Stoke-on-Trent, lately carried on by Messrs. Renshaw, King, and Co., at which place the company are able to cope with any demands which may be made for heavy mechanical engineering work such as boilers, engines, central station dynamos, cranes, tanks, girders, hydraulic presses, etc. Then again the important and growing business of electrical and steam launch building has been added to the other resources of the company by the purchase of the business of Mr. W. S. Sargeant, of Chiswick. Important branch offices have been opened in distant parts of the world—viz., Sydney, Melbourne, and Johannesburg; while other depots such as Alexandria, Amsterdam, Barcelona, Bath, Bombay, Buenos Ayres, Cadiz, Cork, Dunedin, Hamburg, and Yokohama have been opened.

At their Cadby Hall Works the company have erected a huge new building to accommodate their largely-increasing business in the manufacture of lamps, switches, fuses, switchboards, instruments of all descriptions, etc. To provide the necessary power they are adding a large pair of compound engines, and the necessary boilers, and the whole of the shafting and tools will be run by electric motors. They have also added a new department for making an accumulator which it is thought will cause the greatest stir yet known in the central station accumulator world, and in addition they have largely increased their electroplating facilities, so as to extend their outdoor work for the trade under the direction of Mr. William Elmore. The company has also during the past year most successfully introduced the following important enterprise—*i.e.*, the International Okonite Company, whose business has very largely increased since its formation, more than bearing out the statements in the prospectus, and whose specialities have been of great assistance to those engaged in furthering the interests of electrical work, more especially in America, where the new works of the company have more orders than they can supply. The company has also aided in the successful sale of the French, German, and Austrian Elmore patents, and the commencement of working under the same. In the important branch of the company's business known as the contract department, in which installation work is carried out, very marked and satisfactory progress has been made, and it is doubtless due to the fact that the principle has been most rigidly adhered to of not accepting or carrying out any cheap or inferior work. The very best materials that can possibly be bought, together with highly-paid skilled labour, are only used, and the company has the satisfaction of finding that a very large proportion of the work secured by them comes through the recommendation of clients for whom they have already worked. In the Yorkshire district alone 42 installations have been carried out by the Bradford branch. Among the more important may be mentioned: London and Yorkshire Bank, York Municipal Buildings, the Bradford Club, Bradford Banking Company, the Borough Buildings, Bradford Borough Court, Public Art Gallery and Free Library. In the Lancashire district, among the larger installations carried out by the Manchester branch, may be mentioned a 700-light plant for Messrs. Dobson and Barlow, engineers, of Bolton, a second order having been received recently. The central station lighting work at Barcelona has been planned out by the company's engineers, and in a short time the new system of incandescent lighting plant, with underground mains, supplied by the company will be in operation. Repeat orders for installation work have been received from the Marquis of Ripon, Savoy Mansions, Crosse and Blackwell, Clowes and Sons, W. H. Smith and Sons, Strand, the Salisbury Club, J. W. Benson and Co., and other well-known firms, while among the more important maintenance contracts may be mentioned those of Draper's Hall, Exeter Asylum, and Lord Brassey; whilst a part of the lighting work at the Edinburgh Exhibition has been carried out, and there is a very large quantity of work now in hand. In the supply department various articles of importance have been introduced to further electrical engineering, and the turnover has increased 100 per cent. in the last 12 months, whilst the new showrooms at 84, Queen Victoria-street will enable the company to place a larger and more varied assortment of the most approved patterns before intending buyers, so as to facilitate selection.

In the business of manufacturing, the company holds the contracts for the London and North-Western Railway Company, the Great Eastern Railway Company, and the Caledonian Railway, and have executed contracts for the Admiralty, the General Post Office, and the Midland Railway, whilst many articles have been manufactured, such as galvanometers, signal repeaters, contact-boxes, signal expansion tubes, firing keys, numerous electric bells of all sizes, relays, telephone and electric lighting switchboards, train-starting and saloon indicators, single-needle block instruments, lightning protectors, fusible and automatic cut-outs, lamps, tachometers, automatic oil filters, many thousands of switches of all sizes from five amperes upwards, large contracts for brass castings, automatic boxes, automatic advertising, coin-checking and other automatic machinery, lathes, drills, screw-making machinery, and other tools specially adapted for electrical work. Amongst other heavy engineering work carried out at Kidsgrove may be mentioned complete electrical and mechanical plant for a small central station at Palace-chambers, Westminster; complete mechanical and electrical plant for Woking central station; contract for supplying and laying 15 miles of mains for the Audley Local Board Water Works, together with compound engines, boilers, 100ft. deep well and pumps; gas works plant for Birkenhead Gas Committee; petroleum storage tanks about 70ft. in diameter, capable of holding 2,000 to 2,500 tons of oil, for the Mersey Dock and Harbour Board of Liverpool; seven locomotive steam cranes of from five to 25 tons capacity, together with many high-class engines and boilers, including steel boilers 32ft. in length, water softeners, etc. A considerable number of electric launches have been built at the company's yards at Chiswick, amongst them being the "Volt" (the fastest ever built for her size), and various launches from 28ft. to 31ft. long, having an average speed of about 8½ miles per hour. For the English Government a very important departure has been made in building an electric pinnace capable of carrying 40 soldiers—another pinnace of this class having been already built for a steam yacht. Four steam launches, from 30ft. to 52ft. in length, have been also built, the largest one being for the Mexican Government. As steel launch building requires special appliances, a special yard has been recently laid out for building steel launches of every description. The company, after writing £7,000 off patents account, paid a dividend for the year of 15 per cent., put £25,000 to reserve fund, and carried forward over £16,000.

WOODSIDE ELECTRIC WORKS.—During the past year this firm has been exceptionally busy; in fact, for some time during the autumn they had as much work as they could well undertake. The principal work has been the supply and erection of complete isolated installations of electric light in factories, yards, and steamships, and the increasing demand for the Woodside dynamos, arc and superincandescent lamps, and fittings generally, is very encouraging. The outlook for 1891 is hopeful. They start the year with a large number of orders already booked, and many installations which have been erected in factories with a view to larger installations, if successful, will doubtless result in a large amount of business.

Deptford Station.—The London Electric Company are busily engaged in putting in order their distributing stations at the Grosvenor, as well as the other sub-stations, but there does not appear to be any possibility of the lighting being resumed for another two or three weeks.

UNDERGROUND MAINS.—II.

THE CROMPTON SYSTEM.

(Continued from page 9.)

In laying out a system of mains the position of the generating station is taken as centrally as possible. The streets are laid out with mains in the simplest and most direct manner, and feeder points are then determined upon at various points upon the plan. In the streets where no feeders are required a culvert for three wires only is laid, but where one pair of feeders go alongside the mains, a culvert for five wires (the three wires and one pair of feeders) is necessary. Near the station where feeders in two directions are required, culverts for seven wires (three wires and two pairs of feeders) are laid, and so for other parts of the circuit. These three sizes are shown in the illustrations. The sizes inside are respectively 1ft. 3in., 1ft. 8in., and 2ft. wide.

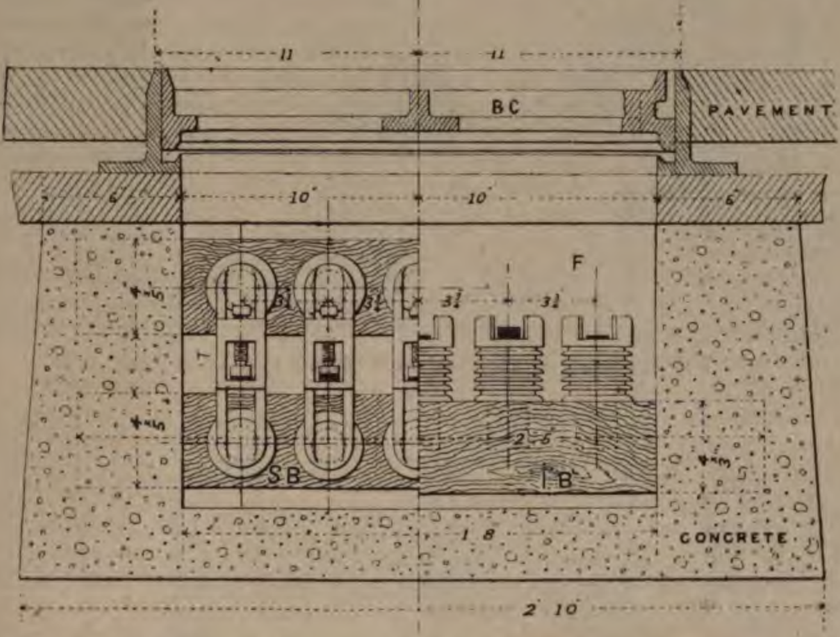

FIG. 4.—Section of Culvert—3-wire mains with one pair of feeders.

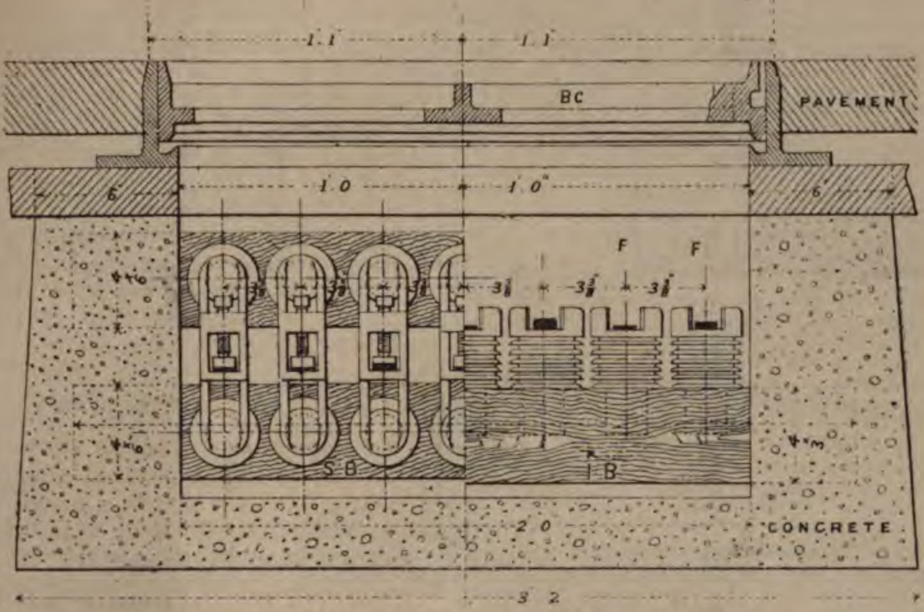

FIG. 5.—Section of Culvert—3-wire mains with two pairs of feeders.

The trenches for the culverts are made, wherever possible, under the pavement, and the usual type of boxes are made for this situation. Occasionally, however, it is necessary to lay the mains in the roadway for some length, or to cross the road from one side to the other, and the culverts and boxes are then made extremely strong to withstand the ordinary traffic or even the passage of a steam roller.

The size of trench for the ordinary main on the Crompton system is 2ft. 5in. wide, and for the largest culvert 3ft. 2in. wide by 1ft. 9½in. deep.

The first process, when actual laying is begun, is the digging of the trenches and the construction of the culverts. These are laid in concrete, of the required width of opening, with the walls biased outward at the base for strength; first the floor is laid in concrete, and then the walls of the culvert, which are kept up by rough boarding till firmly set.

The second part of the work is the construction of insulator boxes. At every alternate house along the road—roughly, at the distance of every 15 yards—arrangements for an insulator box are made. This box serves both for allowing inspection of the insulator and as a junction box for either of the houses. An oak baulk, 4in. by 3in., for supporting the insulators, is embedded in the concrete, each baulk having round holes drilled in its centre for the after reception of the insulator. These insulator baulks are marked with the letters I B on the figures.

Thick York flagstones are now placed along over the culverts, and the surface is filled in and rammed down and the pavement replaced. At the places for insulators a metal frame is bedded in the concrete. Each of these frames has a properly fitting lid or box cover, B C, and these box covers are previously filled in level with concrete, so as practically to form one continuation of the pavement itself.

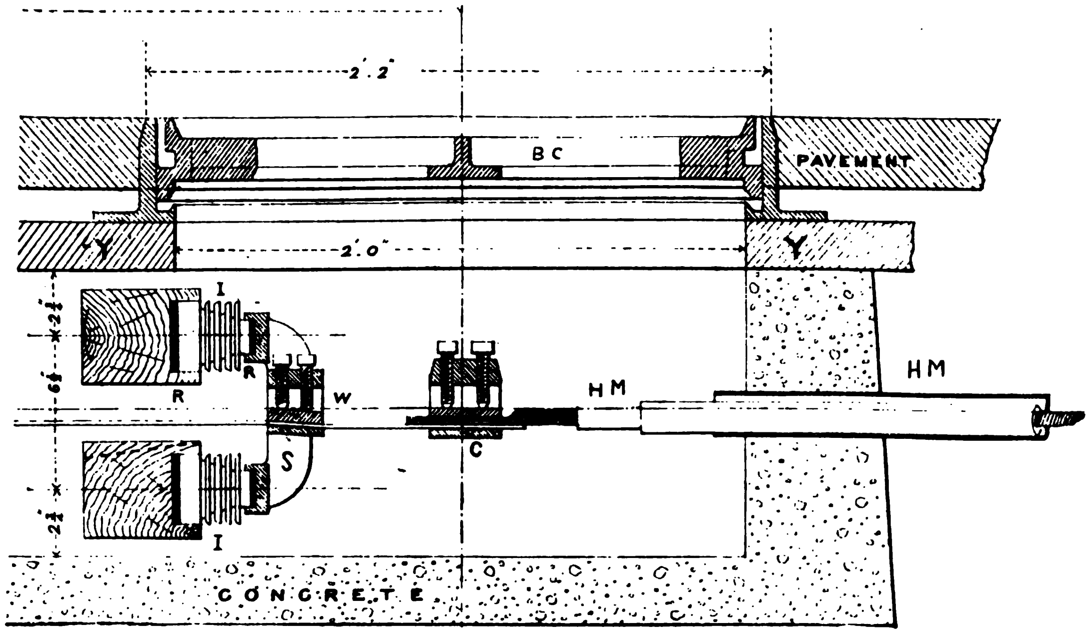

Fig. 6.—Straining Piece and Joint of Strip to Cable in Pipe.

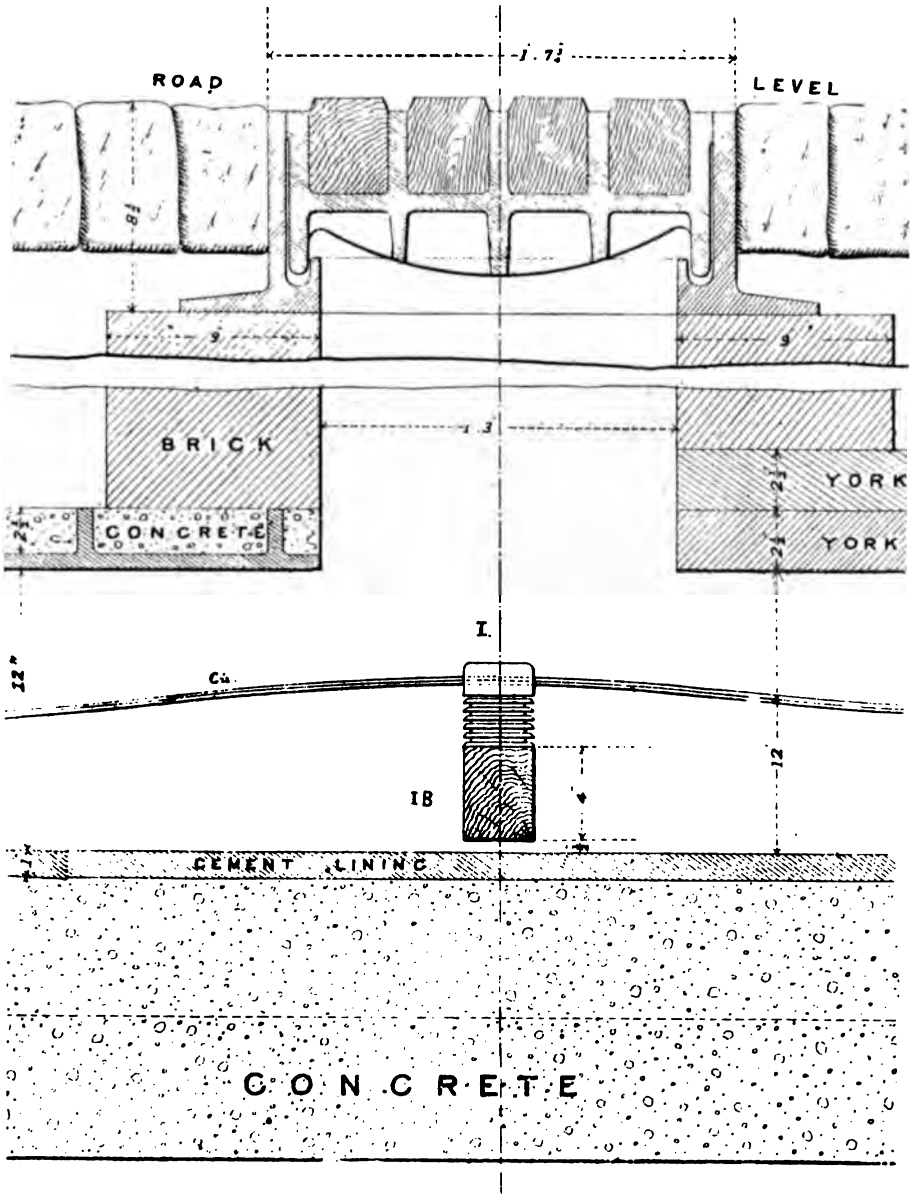

Fig. 7.—Insulating Box in Culvert under Roadway. Longitudinal Section, showing alternative systems with York stone or iron and concrete covering.

At certain distances along—from 20 yards up to 100 yards if the road is straight—provision is made for straining-boxes. Two baulks of oak are firmly bedded in the concrete one above the other, and form the fixed parts to take the strain of the copper strips. The size of the baulks is 4in. by 4in. for ordinary mains, 4in. by 5in. for mains with one pair of feeders, 4in. by 6in. for mains with two pair of feeders. These straining baulks are marked S B in the illustrations. After they are laid the spaces above are covered in with cast-metal boxes and covers of the same type as the others.

(To be continued.)

TRANSMISSION OF POWER BY MANILLA ROPES.*

This paper, by Mr. J. H. Gregg, which was read before the Western Society of Engineers, contrasts the English system of separate ropes for transmitting power from the prime mover to line shafts with the American system, in which one continuous rope is employed, independently of the number of grooves in the sheaves, with an automatic tension-carriage for taking up slack and giving tractional force, which is dependent on the weight applied to the pull-back. The sheaves for American rope gearing are of two kinds, drivers and idlers, or carrying sheaves, distinguished by the form of the grooves, which for drivers include the angle 45deg., and for idlers are semicircular in section.

Mr. Gregg quotes a safe formula for ordinary practice, constructed by E. D. Leavitt, jun., for the horse-power of driving ropes, as follows :

$$\text{H.P.} = \frac{G \times D \times R}{200} v.$$

G = circumference of rope.
D = diameter of sheaves in feet.
R = revolutions per minute.

The annexed table was calculated by means of the above formula :

Rope Transmission of Power.

Speed in feet per minute.	1000	1500	2000	2500	3000	3500	4000	4500	5000
Diameter of rope.	Horse-power.								
Inches.									
¾	1¾	2¾	3½	4½	5½	6½	7	8¼	9
1	3¼	4⅛	6½	8	10	11	13	15	16
1¼	5⅛	7½	10¼	13	15	18	20	23	26
1½	7½	11	15	18	22	26	30	34	37
1¾	10	15	20	25	30	35	40	45	50
2	13	19½	26	33	39	46	52	59	65

The margin of safety, according to this table, appears to be considerable. The Chicago Arc Light and Power Company run successfully 50 light dynamos with two ¾in. ropes, travelling at a speed of 3,516ft. per minute, and transmitting 50 h.p., or about four times as much as would be calculated from the table.

The average breaking strength of the manilla rope is about 10,000lb. per square inch of section.

INDUCTANCE AND ITS PROPOSED UNIT THE HENRY.†

BY A. E. KENNELLY.

(Concluded from page 11.)

Thus far we have only considered the centimetre or absolute unit, whose unfitness for practical use is evident, since the smallest inductance that is at present known to engineering amounts to several thousand, while the average values met with are counted in millions of centimetres. It would, of course, be possible to name suitable units from the metrical system of lengths, but it is the proposal of this institute to adopt the word "Henry" as the practical unit, in honour of the man who, beyond all doubt, was among the foremost to extend the knowledge thus far possessed of self and mutual inductance.

If the selection of the practical unit were entirely free and subservient only to practical requirements, so that its magnitude should express ordinary values in digits with fewest decimals on the one hand, or large numbers on the other, there seems most reason to believe that the thousandth of the earthquadrant or myriametre would be the most eligible.

Proposed name.	Length.	Number of centimetres.	Unit.
Henry.	Earth quadrant.	1,000,000,000	Practical unit.
		100,000,000	
		10,000,000	
Millihenry.	Myriametre.	1,000,000	
	Kilometre.	100,000	
	Hectometre.	10,000	
Microhenry.	Decametre.	1,000	
	Metre.	100	
	Decimetre.	10	
	Centimetre.	1	Absolute unit.

Of course large iron machines employing many turns of wire linked by dense magnetic fields would have inductances more appropriately expressed in earth quadrants, which might then be termed the kilohenry just as we now have the watt and kilowatt, but there is one restriction which makes such a selection undesirable, and that is the hitherto unbroken system of practical units itself. This practical system is a sub-scheme of the great international C.G.S. system, and especially planned for adaptability to practical requirements. It is derived from that parent system by the substitution for the unit of length, one thousand million centimetres in place of one centimetre, and for the unit of mass an impalpable entity definite only in thought, the one hundred millionth of a milligramme in place of the gramme. By this substitution in the C.G.S. electromagnetic units, we obtain the hitherto unbroken system of the volt, ohm, ampere, coulomb, joule, watt, and farad. Even these units are not always the most convenient, witness, for example, the microfarad in common use, whose prefix is maintained simply in deference to the harmony of the system, for the farad is a capacity that exists only in imagination ; the capacity of the earth itself being only about 700 microfarads, and of the sun—or, rather, a sphere having the apparent dimensions of the sun—being only about 76,000 microfarads. On the other hand, a proposition has lately been made to infringe the system by making the volt, the ampere and the watt, ten times their present values, on the ground of practical convenience. However, at the present time, it would surely be unadvisable to attempt the precedent of infringing a system that has hitherto been supported by time, custom, and international congress.

In this practical system, the unit of inductance must be 1,000 million centimetres. That is an earth quadrant or the distance from the pole to the equator, measured on the meridian of Paris. Strictly speaking, it is only the quadrant of the French standard earth, which is about one-tenth of 1 per cent. shorter than the acknowledged actual earth quadrant, according to the best determinations, but the fact of the latter being 10,001 kilometres instead of 10,000, is a matter of precision in definition only and in no way affects the practical unit.

As regards the history of the subject, it would appear that prior to 1887, measurements and deductions were confined to scientific works, and were expressed in absolute units—centimetres. In that year, however, a paper was read before the British Institution of Electrical Engineers by Messrs. Ayrton and Perry, who invented and developed a practical measuring instrument for the measurement of inductance, who, aided by Dr. Sumpner, made important contributions to the literature of the subject, and who proposed a name provisionally for the practical unit. That name was the secohm, a contraction of second-ohm, implying the fact that the product of the two was the length equal to the practical unit. They drew attention to the fact that since the Paris Congress of 1884 had fixed the standard legal ohm as the resistance of a column of mercury at zero centigrade, 106 centimetres long and one square millimetre in cross-section, whereas the true ohm was in all probability 106·3 centimetres, or one-quarter of 1 per cent. greater, the inductances measured in the manner they suggested from seconds and legal ohms, would be in terms not of the standard earth quadrant of 10,000 kilometres, but of legal earth quadrants 9,778 kilometres in length. The difference practically is not very great, but to avoid error or confusion in definition they advocated provisionally the term secohm in place of quadrant.

The Paris Congress of 1889 adopted the "quadrant" as the practical unit of inductance, defining it as 1,000 million centimetres.

The practical range of inductances is second only to that of resistances, and the latter we know from a few microhms up to thousands of megohms. The smallest inductances are those of Hertz resonators which descend to the order metres. Excluding these, however, the smallest are perhaps met with in measuring instruments intended to have negligibly small inductance, such as doubly wound resistance coils, Cardew voltmeters, and the like. These descend to the order of decametres, and can generally be expressed as such without prefixing decimal points. It is evident that the term microhenry would suitably apply to their designation. At the other end of the scale we find large induction machines linking dense fields with many turns of wire, and reaching inductances of hundreds or even thousands of henrys. Intermediate between these limits, there exists a large class of circuits having many turns but little iron, or clad in iron with few turns of wire, and these seem to be best expressed by the term millihenry, equivalent to the myriametre.

---

* From "Abstract of Papers," published by the Institution of Civil Engineers.

† A paper read at the fifty-second meeting of the American Institute of Electrical Engineers.

With the object of setting forth the advantages to be derived from the use of this nomenclature, it may be permissible to adopt it provisionally in describing the measurements that follow. These measurements have been made on different types of apparatus at different times and by different methods, so that they represent mean values from several observations in many cases, but allowance must be made for the variations of standard and type.

In telegraphy, the inductance of an ordinary Western Union 140-ohm relay is about three henrys with the armature drawn well back, and nine henrys with the armature pressed against the poles; in the latter case, of course, the magnetic reluctance of the iron circuit is a minimum, and the same current in the coils causes three times as many lines to circulate through the iron. At the position of the armature in ordinary adjustment the inductance is about five henrys.

The inductance of an ordinary standard 10ω relay is from 200 to 500 millihenrys, according to the position of the armature relatively to the poles.

The inductance of an ordinary sounder is similarly from 25 to 50 millihenrys. These inductances are the values obtained with only a few milliamperes through the coils, and since the path of the induction is largely through iron, the inductance varies with the strength of the current used. Practically, however, the variation is small within the range of current at which instruments usually operate.

SUBMARINE TELEGRAPHY.

The inductance of a mirror speaking galvanometer of the ordinary type having 2,250 ohms was found to be 3·6 henrys.

TELEPHONY.

The inductances met with in the ordinary long-distance telephone apparatus are as follows:

The call bell 80 ohms and 1·4 henrys.

The magneto armature 550 ohms, and from 2·7 henrys with the plane of the coil in the line joining the poles, to 7·3 henrys when the iron core joins the poles, the plane of the coil being then at right angles to the magnetic flux.

The induction coil primary 0·28 ohm and 3·5 millihenrys.

Secondary 164 ohms, and 734 millihenrys.

The mutual inductance between the coils 60 millihenrys.

The Bell telephone receives 75 ohms, and from 75 to 100 millihenrys. The removal of the diaphragm from an ordinary telephone of this type reduces the inductance about 35 per cent. All these inductances are to currents of a few milliamperes only. As regards the inductance of aerial line wires, it is to be regretted that measurements are not yet forthcoming, and indeed the experimental determination is attended with some difficulty, owing to static capacity and imperfect insulation. In the absence of direct measurements, theory indicates that the inductance of overhead copper wires depends upon the elevation above the ground as well as upon the diameter. In the case of iron wires as used in telegraphy, the permeability of the iron enters as an additional factor. The following table of inductances for copper wires, is based upon a formula first given by Clerk Maxwell.[*] It is to be hoped that experimental evidence may shortly be collected corroborating these results:

TABLE OF INDUCTANCE OF COPPER AERIAL LINE WIRE, PER KILOMETRE AND MILE, FOR DIFFERENT DIAMETERS AND ELEVATIONS ABOVE THE GROUND.

Diameter of wire.		Elevation above ground 400 cm. or 13·1ft.		Elevation above ground 700 cm. or 23ft.		Elevation above ground 1,000 cm. or 32·8ft.		Elevation above ground 1,300 cm. or 42·7ft.

1·00	0·394	1·526	2·456	1·638	2·635	1·709	2·750	1·761	2·834

The inductance of iron wires, in the absence of measurements, is almost too doubtful to justify calculation, being perhaps 10 times more than the inductance of copper wires under similar conditions. The difficulty in their case lies in assigning the proper value of permeability.

ELECTRIC LIGHT AND POWER.

Dynamos and dynamo-electric machinery are, of course, generally characterised by large inductances.

The inductance of the field magnets of a dynamo may have any value depending on the size and voltage of the machine from one henry up to 900 amperes.

The inductance of an armature may similarly vary from 20 millihenrys up to 50 henrys between brushes. One millihenry is a fair average value of the inductance of one section of an armature. Armature inductances depend not only on the strength of the measuring current, but also upon the strength of the field, and whatever influences the permeability of the core.

The inductance of an alternating transformer varies from a primary of 400 millihenrys, a secondary of one millihenry and mutually 20 millihenrys with a transformation ratio of 20, up to corresponding values perhaps 100 times as great.

APPARATUS. THE INDUCTANCE OF RUHMKORFF COILS.

The smallest medical coil in ordinary use has five millihenrys in its primary, 100 millihenrys in its secondary, and 20 millihenrys mutually between them.

A large inductance coil 19in. long and 8in. in diameter has 0·145 ohms and 13 millihenrys in its primary, 30,600 ohms and 2,000 henrys (by two concordant methods of measurement) in its secondary, and 163 henrys mutually between them.

The inductance of a mirror galvanometer may vary from a few millihenrys up to 10 or more henrys according to its resistance. Two henrys is a fair average for an astatic mirror galvanometer of 5,000 ohms.

An ordinary electric bell of 2·5 ohms resistance was found to have an inductance of 12 millihenrys.

There is one point in connection with the self and mutual inductance of induction coils and transformers, that deserves attention owing to the confusion that occasionally arises concerning it. It may be, perhaps, best represented by a numerical example. Let a closed Faraday ring of iron, 100 centimetres in mean circumference and 20 square centimetres in uniform cross-section, be closely wound with a primary coil of 2,500 turns in one layer, followed by a secondary coil of 7,500 turns, also in one layer. If now two amperes be maintained steadily through the primary, the magnetic force in the iron will be $4\pi/10$ times the ampere-turns per centimetre of the iron circuit, or $4\pi/10 \times 2 \times 2{,}500 \div 100$, or 62·85. The permeability of wrought iron at this force being, say, 250, the induction developed per square centimetre will be 250 × 62·85, or 15,713 lines, and the total induction enclosed by the primary coil, neglecting the space occupied by the wire itself, will be 20 × 15,713, or 314,250 lines, which traverse every turn of both windings. The linkages with the primary will be 2,500 × 314,250, or in round numbers 786,000,000, and referred to one ampere, half this number, or an inductance of 393 million centimetres—that is, 393 millihenrys. Similarly, the linkages of these lines with the secondary will be 2,358 millions, and per ampere of primary current 1,179 millions of centimetres mutual inductance or 1·179 henrys. Next suppose the primary current interrupted, and a current steadily established in the secondary sufficient to produce the same magnetic force in the iron, thus avoiding the complication of a changing permeability. As the secondary has three times as many turns, the current effecting this will be two-thirds of one ampere. The total induction through the iron will now be the same as before and therefore the linkages will be equally numerous. The self inductance of the secondary will be $2{,}358{,}000{,}000 \div \frac{2}{3}$, or 3,537,000,000 centimetres, that is 3·537 henrys. The mutual inductance will similarly be $786{,}000{,}000 \div \frac{2}{3}$, or 1·179 henrys as before. It will be found on carrying the reckoning to the necessary degree of accuracy, that this mutual induction, 1·179, is the square root of the product of the two self-inductances, 0·393 × 3,537.

Examination of the steps in this calculation will show that this proposition must hold for all closed magnetic circuits uniformly magnetised to the same degree when the space occupied by the windings is not taken into account. Under the opposite conditions of open and especially of short iron cores, with large winding spaces, the condition usually fails, and the mutual inductance may be greater or less than the square root of the self-inductances multiplied together.

Another reason in favour of selecting 1,000 million centimetres as the value of the practical unit or henry, is the desirability of having the time-constant of an electromagnetic circuit expressed directly in seconds by its practical units as in the case of electrostatic circuits, rather than revert to a unit of inductance that would yield the time-constant in milliseconds or other fractional period of time. The time constant of a simple electromagnetic circuit, a circuit having inductance and resistance, but negligibly small electrostatic capacity, is defined as the ratio of its inductance to its resistance—that is, of its henrys to its ohms. It is an important function, and its consideration presents some remarkable analogies between inductance and electrostatic capacity that it is interesting to trace.

Imagine an inductance coil, C, without iron to be supplied with a steady current from an E.M.F., E, of 50 volts. Let the inductance of the coil be three henrys, and its resistance 10 ohms (Fig. 2.) Ohm's law determines the strength of the current to be five amperes. Now short-circuit the terminals of the coil very suddenly by a wire across its terminals of negligible resistance. The current in the coil, C, does not stop instantly, but under the name of extra current is maintained in the coil by reason of its inductance. According to theory, the last dregs of the current will never entirely vanish from the coil, although after the first few seconds the remainder is exceedingly small. The very first instant after short-circuiting, the current continues at five amperes by its electromagnetic momentum, but being unsupported, its energy is lost thermally in overcoming the coil's resistance, and it immediately falls. In falling, the lines of force linked with the circuit and sustained by the current are drawn in, cutting the coil as they recede, thus creating a counter E.M.F. tending to prolong the current, and this process of dwindling current with reduction of opposition from the reserve of inductance descend together. The total quantity of electricity that will flow through the circuit under the conditions specified may fairly be called the charge or discharge of the coil, and it can be readily proved that this charge is equal to the quantity that would be conveyed by the initial discharging current, acting uniformly during a time equal to the time-constant of the circuit. In this case the discharge commenced at five amperes, and the time-constant is 0·3 second, so that the total discharge will be that due to the flow of this current in 0·3 seconds—that is 1·5 coulombs.

---

[*] Clerk Maxwell. "Electricity and Magnetism," Second Edition, I., p. 293.

To represent the case graphically, suppose the curve of discharge in time to be plotted as in the figure. Let the axis O X be divided off into seconds, and the axis O Y into amperes. (Fig. 3.) The discharge commences at five amperes, subsides rapidly at first, but at last so slowly that an indefinitely long time must elapse before it altogether disappears. The area enclosed between the curve and the axes represents ampere-seconds or coulombs to the amount of the total charge, and the proposition just stated asserts that if the current had continued at five amperes steadily for 0·3 seconds, the area of the dotted rectangle so generated, Y D T O, would be equal to the total area enclosed between the curves and the axes prolonged to the ultimate point of union.

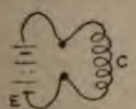

Fig. 2

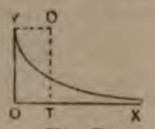

Fig. 3

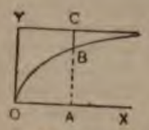

Fig. 4

Curiously enough, exactly the same law applies to the discharge of a condenser through a circuit of resistance but negligibly small inductance. The time-constant of the circuit in this case, however, being its capacity in farads multiplied by its resistance in ohms.

The curve of discharge is of the same type for inductances or capacities. It is logarithmic, and finds its prototype in the case of the discharge of water in time from a tank having a faucet at the base, assuming that the rate of escape through the faucet at any moment is directly proportional to the pressure or level of water then remaining in the tank.

The laws which control the outline of this discharge curve are identical for condensers or short-circuited inductances, and are combined in the following enunciation:

The natural logarithm of the ratio of the $\left\{\begin{array}{c}\text{full charge}\\ \text{initial current}\end{array}\right\}$ to the $\left\{\begin{array}{c}\text{residual charge}\\ \text{discharging current}\end{array}\right\}$ at any instant is the quotient of the time during which discharge has been in progress by the time-constant of the circuit.

In this statement two reservations are necessary.

The electrostatic circuit must be free from all appreciable inductance, and the electromagnetic circuit must contain negligibly small electrostatic capacity. It was first pointed out by Sir William Thomson that the discharge of a condenser through an inductance circuit, becomes oscillatory when the inductance exceeds a certain critical value.

When an inductance discharges through a break instead of a closed circuit, the conditions become complicated to a degree that eludes complete practical solution in the present state of knowledge.

At the period of natural discharge equal to the time-constant, an inductance or capacity charge or current will have fallen to 36·8 per cent. of its initial value.

Similar propositions relate to the charging currents and quantities. In the above instance, after the coil has completely discharged, remove the short-circuiting wire. The current will immediately enter the coil, and the curve of its arrival in time is represented in Fig. 4, this curve being only an inversion of the preceding. For this reason it is evident that the area above the curve now represents the charge, and by an extension of meaning, the deficit from full current, such as B C, may be called the charging current, since on discharge and reversal of the diagram, this will be the discharging current at the same lapse of time. In fact, the current A C is doing work in heating the coil, the deficit from ultimate current, B C, being only active in increasing the electromagnetic momentum of the circuit, and work is really stored in the coil as though the deficit current did exist. A similar but inverted curve of current in time represents the charge of a condenser. In each case and under the above restrictions the following propositions hold:

The natural logarithm of the ratio of the $\left\{\begin{array}{c}\text{full charge}\\ \text{initial current}\end{array}\right\}$ to the $\left\{\begin{array}{c}\text{deficit from full charge}\\ \text{charging current}\end{array}\right\}$ at any instant is the quotient of the time during which the charge has been in progress by the time-constant of the circuit.

When the charging interval reaches the time-constant, the charge will have attained 63·2 per cent. of its full value.

Another relation between simple electrostatic or electromagnetic circuits and their time-constants is in their stores of energy. The energy of the charge in each case is half the energy that would be developed by the initial charging or discharging current against the ohmic resistance of the circuit in the time equal to the time-constant. In the above instance, for example, five amperes being the initial charging or discharging current, and the resistance 10 ohms, the circuit energy of this current per second would be 5×5×10=250 joules, and during half the time-constant the energy thus developed would amount to 0·3×250÷2 or 37·5 joules. This is the electromagnetic energy stored up in the charge.

These are not the only analogies that exist between inductance and capacity, but there are remarkable points of diversity. The discharge of extra current of a coil is in the same direction as the circuit current, with the condenser it is the reverse. In a great many practical instances the electromagnet and the condenser are used to annul each other's influence.

The time-constant of an inductance circuit is generally small, for the reason that a coil of large inductance has generally many turns, and, therefore, high resistance, so that the ultimate ratio of the henrys to the ohms is not large. For example, the time-constant of a Bell telephone, considered in itself or on short circuit, is from the measurement above described about 0·09 ÷ 75 or 0·0012 seconds, and therefore a steady E.M.F. of, say, two volts, impressed directly upon such a telephone would produce in this interval of time 63·2% of 2/75 amperes—namely, 169 milliamperes. By adding inductanceless resistance to the circuit, however, and raising the E.M.F. proportionately, the time-constant would be lessened, and the arrival of current accelerated. Strictly speaking, this reasoning is inaccurate, since the telephone coil surrounds iron; but with the small currents usually employed, the iron probably does not greatly influence the arrival curve. In the case of dynamo field magnets, and large iron-clad inductances generally, the divergence of the arrival curve from that of a corresponding simple electromagnetic circuit is considerable.

There are several methods by which self and mutual inductance can be measured, the selection depending on the magnitude to be determined and its nature. The Ayrton and Perry secohmmeter, or double revolving commutator, is perhaps the most generally useful. It may be employed in connection with a standard condenser, a standard inductance, or apparent change of resistance with speed. Being used in the Wheatstone bridge, the currents it can alternate are necessary limited in strength.

For small inductances, [*]say, less than one-tenth of a millihenry, the method of Prof. Hughes,[†] or its modification by Lord Rayleigh is probably best suited, using two coils of mutual inductance and a telephone as the observing instrument.

The inductance coils are usually in the form of two concentric rings, the inner being capable of rotation about the common vertical. The mutal inductance of such a pair of coils is a complex function of the dimensions and the angle between the planes at which the coils may be set. It is usual to calibrate the instrument by separate measurements of the inductance at different angles. A simpler arrangement, however, for mutual inductance is a short solenoid in the bridge circuit superposed coaxially upon a long solenoid in the battery circuit. Adjustment to silence in the telephone for interrupted currents is then made by including in the bridge circuit a greater or less number of turns in the outer solenoid. The mutual inductance is then very nearly proportional to the number of turns so included, and by suitable proportions in construction, the accuracy can be carried as far as the telephone for the receiver will permit.

For the measurement of inductance in coils on iron machinery, the ballistic galvanometer is frequently employed, either by the method of discharge for self-inductances, or induced quantity with mutual inductances. Mutual inductances connected by closed iron circuits present no difficulty when great accuracy is not required, since, as already observed, the self-inductances are calculable in these cases with the mutual inductance, and the number of turns in the coils are known. It is much more difficult, however, to measure the self-inductance of the field magnet of a dynamo when the armature is removed, and when currents of the normal exciting strength are used in the measurement. The best attempt has been made apparently by observing the discharge effects of gradual small changes of a strong current passing through the coil, in circuit with a specially arranged Wheatstone bridge.[‡] If it were of sufficient practical importance, however, to measure such inductances with powerful currents, a recording instrument might be tried, having a very light and swiftly-moving pointer, leaving a trace of its motion on a strip of moving paper like Sir William Thomson's siphon recorder. If such a pointer were arranged to give an amplitude of movement at right angles to the paper strip, in proportion to the current traversing the coil, it would register the curve of discharge when the coil was short-circuited in the manner described above. On a sufficiently enlarged scale, corrected perhaps for residual inertia in the moving parts, this curve would give not only the total quantity of discharge, but its deviation from the logarithmic line of simple electromagnetic discharge would give the means of determining the characteristic of magnetisation in the iron.

Of far less importance than the selection of the practical inductance unit, but still well worthy of separate consideration, is the selection of appropriate symbols to represent the unit briefly. It might perhaps be advantageous to represent the henry by a capital H, and the millihenry by the plain letter h. This notation would enable such an inductance as 50 henrys to be written as 50 H, and 50 millihenry as 50 h. The microhenry occurs so seldom that it would probably not need a symbol.

All measurements of precision should employ true ohms and not legal ohms in the computations. The best existing value of the true ohm is 1·0028 legal ohms.[*]

[‡] *Phil. Mag.*, Feb., 1889. Dr. Sumpner.

The correction is practically so small that it can best be carried out by altering the nominal standard temperature of the resistance coils adopted. These temperatures should be increased by 9·4deg. C. for platinum-silver, 6·5deg. C. for German silver, and 13·5deg. C. for platinoid. Thus, a resistance-box with platinum coils standardised for legal ohms (of 106·0 cm.), at 15deg. C. would give true ohms of 106·3 cm. at 24·4deg. C. as the best approximation, and this would be the standard temperature of the box for use in precise measurements of inductance.

THE ELECTROMAGNET.[†]

BY PROF. SILVANUS P. THOMPSON, D.SC., B.A., M.I.E.E

LECTURE IV.

(Continued from page 18.)

Now, these things can be not only predicted by the help of such a law as that, but verified by experiment. Here is a set of tubular coils which we use at the Finsbury Technical College for the purpose of verifying these laws. There is one here about 9in. long, one about half that length, another just a quarter. They are all made alike in this way, that they have exactly the same weight of copper wire, cut from the same hank, upon them. There are, of course, more turns on the long one than on the shorter, because with the shorter ones each turn requires, on the average, a larger amount of wire, and, therefore, the same weight of wire will not make the same number of windings. We use that very simple apparatus, a Salter's balance, to measure the pull exerted down to different distances on cores of various lengths. You find in every case the pull increases and becomes a maximum, then diminishes. We will now make the experiment, taking first a long plunger, roughly about twice as long as the coil. The pull increases as the plunger goes down, and the maximum pull occurs just when the lower end gets to the bottom; beyond that the pull is less. Using the same plunger, with these shorter coils, one finds the same thing; in fact, more marked, for we have now a core which is more than twice the length of the coil. So we find, taking in all these cases, that the maximum pull occurs, not when the plunger is half way in, as the books say, but when the bottom end of it is just beginning to come out through the bottom of the coil that we are using. If, however, we take a shorter plunger, the result is different. Here is one just the same length as the coil With this one the maximum pull does occur when the core is about half way in; the maximum pull is just about at the middle. Again, with a very short core—here is one about one-sixth of the length of the coil—the maximum pull occurs as it is going into the mouth of the coil; and when both ends have gone in so far that it gets into the region of equable magnetic field, there is no more pull on one end than on the other: one end is trying to move with a certain force down the tube, and the other end is trying to move with exactly equal force up the tube, and the two balance one another. If we carry that to a still more extreme case, and employ a little round ball of iron to explore down the tube, you will find this curious result, that the only place where any pull occurs on the ball is just as it is going in at the mouth. For about half an inch in the neck of the coil there is a pull; but there is no pull down the interior of the tube at all, and there is no measurable pull outside.

Now these actions of the coil on the core are capable of being viewed from another standpoint. Every engineer knows that the work done by a force has to be measured by multiplying together the force and the distance through which its point of application moves forward. Here we have a varying force acting over a certain range. We ought, therefore, to take the amount of the force at each point, and multiply that by the adjacent little bit of range, averaging the force over that range, and then take the next value of force with the next little bit of range, and so consider in small portions the work done along the whole length of travel. If we call the length of travel x, the element of length must be called dx. Multiply that by f, the force. The force multiplied by the element of length gives us the work, dw, done in that short range. Now the whole work over the whole travel is made up of the sum of such elements all added together; that is to say, we have to take all the various values of f, multiply each by its own short range dx, and the sum of all those, writing $\int$ for the sum, would be equal to the sum of all the work; that is to say, the whole work done in putting the thing together will be written:

$$w = \int f\,dx.$$

Now, what I want you to think about is this: here, say, is a coil, and there is a distant core. Though there is a current in the coil it is so far away from the core that practically there is no action; bring them nearer and nearer together; presently they begin to act one on another, there is a pull, which increases as the core enters, then comes to a maximum, then dies away as the end of the core begins to protrude at the other side. There is no further pull at all when the two ends stand out equally. Now there has been a certain total amount of work done by this apparatus. Every engineer knows that if we can ascertain the force at every point along the line of travel the work done in that travel is readily expressed by the area of the force curve. Think of the curve X C X, in Fig. 61, the ordinates of which represent the forces. The whole area underneath this curve represents the work done by the system, and therefore represents equally the work you would have to do upon it in pulling the system apart. The area under the curve represents the total work done in attracting in the iron plunger, with a pull distributed over the range $X X_1$.

Now I want you to compare that with the case of an electromagnet where, instead of having this distributed pull, you have a much stronger pull over a much shorter range. I have endeavoured to contrast the two in the other curves drawn in Fig. 61. Suppose we have our coil, and suppose the core, instead of being made of one rod such as this, were made in two parts, so that they could be put together with a screw in the middle, or fastened together in any other mechanical way. Now first treat this rod as a single plunger, screw the two parts together, and begin with the operation of allowing it to enter into the coil; the work done will be the area under the curve which we have already considered. Let us then divide the iron core into two. First of all put in one end of it; it will be attracted up in a precisely similar fashion, only being a shorter bar, the maximum would be a little displaced. Let it be drawn in up to half way only; we have now a tube half filled with iron, and in doing so we shall have had a certain amount of work done by the apparatus. As the piece of iron is shorter, the force curve, which ascends from X to Y_1, will lie little lower than the curve $X C X_1$; but the area under that lower curve, which stops half way, will be the work done by the attraction of this half core. Now go to the other end and put in the other half of the iron. You now have not only the attraction of the tube, but that of the piece which is already in place, acting like an electromagnet. Beginning with a gentle attraction, it soon runs up, and draws the force curve to a tremendously steep peak, becoming a very great force when the distance asunder is very small. We have therefore in this case a totally different curve made up of two parts, a part for the putting in of the first half of the core, and a steeper part for the second; but the net result is, we have the same quantity of iron magnetised in exactly the same manner by the same quantity of electric current running round the same amount of copper wire—that is to say, the total amount of work done in these two cases is necessarily equal. Whether you allow the entire plunger to come in by a gentle pull over a long range, or whether you put the core in in two pieces—one part with a gentle pull, and the other with a sudden spring up at the end—the total work must be the same; that is to say, the total area under our two new curves must be the same as the area under the old curve. The advantage, then, of this coil and plunger method of employing iron and copper is, not that it gets any more work out of the same expenditure of energy, but that it distributes the pull over a considerable range. It does not, however, equalise it altogether over the range of travel.

A number of experimental researches have been made from time to time to elucidate the working of the coil and plunger. Hankel, in 1850, examined the relation between the pull in a given portion of the plunger and the exciting power. He found that, so long as the iron core was so thick and the exciting power so small that magnetisation of the iron never approached saturation, the pull was proportional to the square of the current, and was also proportional to the square of the number of turns of wire. Putting these two facts together we get the rule—which is true only for an unsaturated core in a given position—that the pull is proportional to the square of the ampere-turns. This might have been expected, for the magnetism of the iron core will, under the assumptions made above, be proportional to the ampere-turns, and the intensity of the magnetic field in which it is placed being also proportional to the ampere-turns, the pull, which is the product of the magnetism and of the intensity of the field, ought to be proportional to the square of the ampere-turns.

Dub, who examined cores of different thicknesses, found the attraction to vary as the square root of the diameter of the core. His own experiments show that this is inexact, and that the force is quite as nearly proportional to the diameter as to its square root. There is again reason for this. The magnetic circuit consists largely of air paths by which the magnetic lines flow from one end to the other. As the main part of the magnetic reluctance of the circuit is that of the air, anything which reduces the air reluctance increases the magnetisation, and, consequently, the pull. Now, in this case, the reluctance of the air paths is mainly governed by the surface exposed by the end portions of the iron core. Increasing these diminishes the reluctance, and increases the magnetisation by a corresponding amount. Von Waltenhofen, in 1870, compared the attraction exerted by two equal (short) tubular coils on two iron cores, one of which was a solid cylindrical rod, and the other a tube of equal length and weight, and found the tube to be more powerfully attracted. Doubtless, the effect of the increased surface in diminishing the reluctance of the magnetic circuit explains the cause of the observation.

Von Feilitzsch compared the action of a tubular coil upon a plunger of soft iron with that exerted by the same coil upon a core of hard magnetised steel of equal dimensions. The plungers, Fig. 62, were each 10·1 centimetres long; the coil being 29·5 centimetres in length, and 4·2 in diameter. The steel magnet showed a maximum attraction when it had plunged to a depth of five centimetres, whilst the iron core had its maximum at a depth of seven centimetres, doubtless because its own magnetisation went on increasing more than did that of the steel core. As the uniform field region began at a depth of about eight centimetres, and the cores were 10·1 centimetres in length, one would expect the attracting force to come to zero when the cores had plunged into a depth of about 18 centimetres. As a matter of fact, the zero point was reached a little earlier. It will be noticed that the pull at the maximum was a little greater in the case of the iron plunger.

---

[*] Report of the Committee on Electrical Standards read before the British Association, September, 1890.

[†] Cantor lectures, delivered before the Society of Arts.

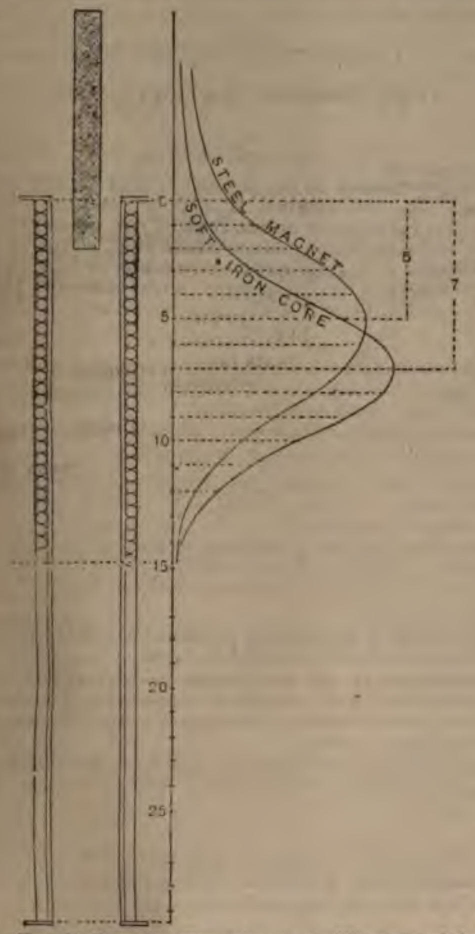

FIG. 62.—Von Feilitzsch's Experiment on Plungers of Iron and Steel.

The most careful researches of late years are those made by Dr. Theodore Bruger, in 1886. One of his researches, in which a cylindrical iron plunger was used, is represented by two of the curves in Fig. 63. He used two coils, one 3½ centimetres long, the other seven centimetres long. These are indicated in the bottom left-hand corner. The exciting current was a little over eight amperes.

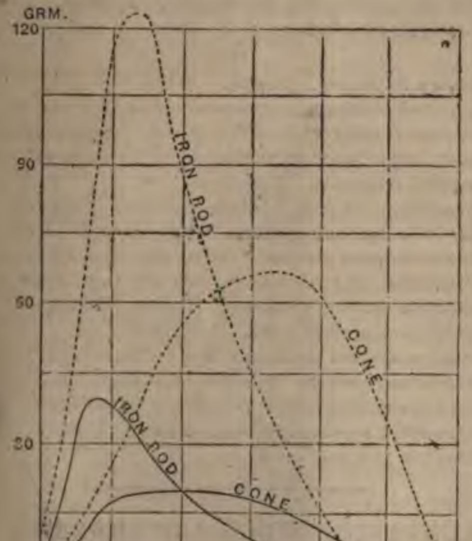

FIG. 63 Bruger's Experiments on Coils and Plungers.

The cylindrical plunger was 39 centimetres long. The plunger is supposed, in the diagram, to enter on the left, and the number of grammes of pull is plotted out opposite the position of the entering end of the plunger. As the two curves show by their steep peaks, the maximum pull occurs just when the end of the plunger begins to emerge through the coil, and the pull comes down to zero when the ends of the core protrude equally. In this figure the dotted rves relate to the use of the longer of the two coils. The height the peak, with the coil of double length, is nearly four times as great, there being double ampere-turns of excitation. In some other experiments, which are plotted in Fig. 64, the same core was used with a tubular coil 13 centimetres long. Using currents of various strengths, 1·5 ampere, 3, 4·8, 6, or 8 amperes, the pull is of course different, but, broadly, you get the same effect, that the maximum pull occurs just where the pole begins to come out at the far end of the tubular coil. There are slight differences; with the smallest amount of current the maximum is exactly over the end of tube, but with currents rather larger the maximum point comes a little farther back. When the core gets well saturated the force curve does not go on rising so far; it begins to turn over at an earlier stage, and the maximum place is necessarily displaced a little way back from the end of the tube. That was also observed by Von Waltenhofen when using the steel magnet.

EFFECT OF USING CONED PLUNGERS.

But now if, instead of employing a cylindrical core, you employ one that is pointed, you find this completely alters the position of the maximum pull, for now the point is sufficient to carry the whole of the magnetic lines which are formed in the iron rod. They do not come out at the point, but filter through, so to speak, along the sides of the core. The region where the magnetic lines come up through the iron into the air is no longer a definite "pole" at or near the end of the rod, but is distributed over a considerable surface; consequently when the point begins to poke its nose out, you still have a larger portion of iron up the tube, and the pull, instead of coming to a maximum at that position, is distributed over a wider range. I am now making the experiment roughly with my spring balance and a conical plunger, and I think you will be able to notice a marked difference between this case and that of the cylindrical plunger. The pull increases as the plunger enters, but the maximum is not so well defined with a pointed core as it is with one that is flat-ended. This essential difference between coned plungers and cylindrical ones was discovered by an engineer of the name of Krizik, who applied his discovery in the mechanism of the Pilsen arc lamps. Coned plungers were also examined by Bruger. In Fig. 63 are given the curves that correspond to the use of a coned iron core, as well as those corresponding to the use of the cylindrical iron rod. You will notice that, as compared with the cylindrical plunger, the coned core never gave so big a pull, and the maximum occurred not as the tip emerged, but when it got a very considerable way out on the other side. So it is with both the shorter and the longer coil. The dotted curves in Fig. 64 represent the behaviour of a coned plunger. With the longer coil represented, and with various currents, the maximum pull occurred when the tip had come a considerable way out; and the position of the maximum pull, instead of being brought nearer to the entering end with a high magnetising current, was actually caused to occur further down; the range of action became extended with large currents as compared with small ones. Bruger also investigated the case of cores of very irregular shapes, resembling, for example, the shank of a screw-driver, and found a very curious and irregular force curve. There is a good deal more yet to be done, I fancy, in examining this question of distributing the pull on an attracted core by altering the shape of it, but Bruger has shown us the way, and we ought not to find very much difficulty in following him.

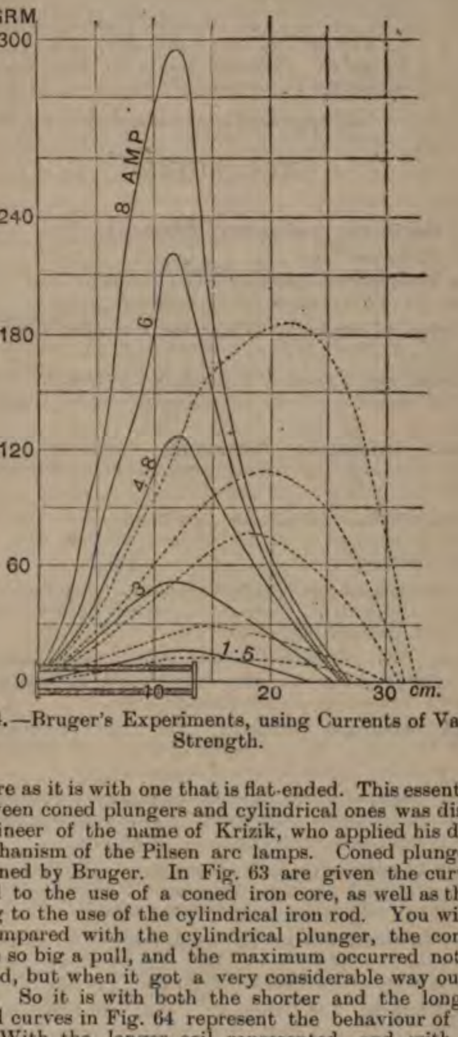

FIG. 64.—Bruger's Experiments, using Currents of Various Strength.

OTHER MODES OF EXTENDING RANGE OF ACTION.

Another way of altering the distribution of the pull is to alter the distribution of the wire on the coil. Instead of having a coned core use a coned coil, the winding being heaped up thicker at one end than at the other. Such a coil, wound in steps of increasing thickness, has been used for some years by Gaiffe, in his arc lamp; it has also been patented in Germany by Leupold. M. Trève has made the suggestion to employ an iron wire coil, so to utilise the magnetism of the iron that is carrying the current. Trève declares that such coils possess, for an equal current, four times the pulling power. I doubt whether that is so; but even if it were, we must remember that to drive any given current through an iron wire, instead of a copper wire of the same bulk, implies that we must force the current through six times the resistance; and, therefore, we shall have to employ six times the horse-power to drive the same current through the iron wire coil, so that there is really no gain.

(To be continued).

NEW COMPANIES REGISTERED.

Birmingham Telegraph Factory, Limited.—Registered by A. Mackenzie, Temple-chambers, E.C., with a capital of £50,000 in £10 shares. Object: to carry on the business of telegraph and telephone engineers and contractors and manufacturers of telegraph and telephone appliances. The first subscribers are:

	Shares.
H. Mason, Arley House, Leamington	1
E. W. Lancaster, 68, Princess-road, Edgbaston	1
P. C. Bytheway, Bank House, Wednesbury	1
J. S. Lewis, The Swifts, Yardley, near Birmingham	1
A. Mason, Arley House, Leamington	1
W. Fowler, 69, Temple-row, Birmingham	1
G. M. Fowler, Longbridge, Warwick	1

There shall not be less than two nor more than four Directors. The first are G. V. Fowler, E. W. Lancaster, and J. S. Lewis. Qualification, 50 shares. Remuneration £250, divisible, and 10 per cent. of net profits after 10 per cent. dividend.

CITY NOTES.

Great Northern Telegraph Company.—The receipts for December were £23,600.

Empire Telephone Company.—The Company has changed its offices from 60 to 171, Queen Victoria-street.

West Coast of America Telegraph Company.—The receipts for the month of December amounted to £5,375.

West India and Panama Telegraph Company.—The receipts for the half-month ended December 31 were £2,603, against £2,705.

Brazilian Submarine Telegraph Company.—The traffic receipts of the Company for the week ended January 2 amounted to £4,668.

Cuba Submarine Telegraph Company.—For the month of December the receipts were £3,000, as compared with £2,995 for the corresponding period.

Direct United States Cable Company.—A quarterly interim dividend at the rate of 3½ per cent. per annum has been declared by the Board, payable on the 24th inst.

Personal.—Mr. William Mather, M.P., left Manchester on Saturday last for Russia. He is expected to return early in February to resume his parliamentary duties.

Eastern Telegraph Company.—The traffic receipts for the month of December were £58,058, against £56,862 in the corresponding period of 1889, or an increase of 1,196.

Eastern Extension Telegraph Company.—The receipts for December amounted to £42,382, as against £40,369 in the corresponding period, showing an increase of £3,120.

Western Counties Telephone Company.—The interest warrants on this Company's 5 per cent. debentures for the half-year ending December 31st, 1890, were posted on the 6th inst.

Direct Spanish Telegraph Company.—For the month of December the receipts were £2,130, against £2,187, or a decrease of £57 as compared with the corresponding period.

Davey, Paxman, and Company.—This firm write that they had removed to 78, Queen Victoria-street some weeks before the late fire occurred which burnt down their old City offices.

Elmore's French Company.—The share certificates of Elmore's French Patent Copper Depositing Company, Limited, are ready to be exchanged for allotment letters and all bankers' receipts.

Western and Brazilian Telegraph Company.—The traffic receipts of the Company for the week ended January 2, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £3,747.

The Phosphor Bronze Company.—The Company have appointed Mr. W. A. Perry, late manager of Messrs. H. H. Vivian and Co., Limited, Birmingham, manager of the Phosphor Bronze Co.'s rolling and wire-drawing mills at Aston-road and Bagot-street, Birmingham.

International Okonite Company.—The Directors state that the profits which have accrued since June enable them to declare, after payment of interest upon debentures, an interim dividend for the six months ending December 31, on the paid-up capital of the Company, at the rate of 8 per cent. per annum upon the preference shares and 10 per cent. per annum upon the ordinary shares of the Company.

PROVISIONAL PATENTS, 1891.

NOVEMBER 29, 1890.

19505. **Improvements in the method of, and in the machinery for, the manufacture of lead or metallic boxes and plates for electric accumulators, and other kinds of lead or metallic boxes, plates, tubes, rods, strips of irregular sections, or plain, ribbed, corrugated, or fluted by hydraulic pressure, in connection with lead-pipe machinery.** Alexander Wylie, Perseverance Iron Works, Johnstone, N.B.

JANUARY 1.

12. **Improvements in terminals for telephones and other purposes.** James Frederick Bennett and Ernest Parker Hides, 30, Violet Bank-road, Sheffield.

40. **Improvements in electricity meters.** George Hookham, 7, New Bartholomew-street, Birmingham.

49. **Element and process for producing constant electric currents.** Walter Wensky, 37, Chancery-lane, London. (Complete specification.)

83. **Improvements in or relating to electric guest calls or the like.** William Phillips Thompson, 6, Lord-street, Liverpool. (Alexander Striemer, United States.) (Complete specification.)

96. **Improvements in printing telegraphic apparatus.** Edmond Bardot, 6, Bream's-buildings, London.

100. **Improvements in suspension insulators for electrical conductors and electrical apparatus.** Walter Claude Johnson and Samuel Edmund Phillips, 28, Southampton-buildings, London.

105. **Improvements in lightning arresters for electric conductors.** Friedrich Haselwander, 4, South-street, Finsbury, London.

JANUARY 3.

128. **An improved means and apparatus for regulating automatically the flow of electric currents.** John Lawrence Lee, 8, Quality-court, London.

NOTES.

Lord Rayleigh has been elected an honorary member of the Institution of Civil Engineers.

"Ironmongery" has begun a series of elementary articles on dynamos, with hints as to fitting up lighting plants.

Patent Law Reform.—The London Chamber of Commerce has appointed a committee to deal with this subject.

Stockholm Contract.—We understand that Messrs. Siemens and Halske have the contract for the Stockholm lighting.

Cassel (Germany).—Messrs. Siemens and Halske are erecting a central station here. The five-wire system will be used.

South Shields.—The National Telephone Company have opened a new exchange at the Albany-chambers, King-street, South Shields.

South Gosforth.—The question of lighting South Gosforth electrically has been referred to the Highways and Lighting Committee of the Local Board.

Chiswick.—The question of running electric bells from the fire station to the men's houses cropped up at the last meeting of the Local Board, but was shelved for a time.

The British Association.—A meeting of the Executive Committee in connection with this association's visit to Cardiff was held last Saturday, at which it was announced that the guarantee fund amounted to £1,726.

Royal Society.—At the meeting of this society yesterday afternoon, Prof. J. J. Thomson, F.R.S., was to read a paper "On the Rate of Propagation of the Luminous Discharge of Electricity through a Rarefied Gas."

Birmingham and Midland Institute.—At the annual meeting of this institute, Sir Robert S. Ball, F.R.S., of Dublin, was elected president for 1891. The annual *conversazione* was held on Wednesday, and was very successful.

Central London Railway.—The revived scheme for constructing this railway proposes to extend it to Shepherd's Bush, instead of stopping at Bayswater. At Shepherd's Bush connection could be made with the North-Western line.

Weybridge.—A draft copy of the Weybridge Electric Supply Order having been laid before the Rural Sanitary Authority, they have resolved to give the Board of Trade and the promoters of the order notice that certain amendments are required.

Institution of Electrical Engineers.—At the next meeting, on Thursday, 22nd inst., at 8 p.m., a paper will be read by Major-General C. E. Webber, C.B. (Ret.), R.E., past-president, on "The Distribution of Electricity, with especial reference to the Chelsea System."

Heating of Conductors.—At a meeting of the Edinburgh Mathematical Society held last week, Mr. John M'Cowan, of University College, Dundee, read a paper on the heating of conductors by electric currents and electric distribution in conductors so heated.

Leamington.—A special meeting of the Town Council is to be held on the 10th of February, at the request of the agents for the Midland Electric Light Company, to pass a resolution in favour of their order. As the Town Council is running an order on its own account the resolution is little likely to be passed.

University College, Dundee.—On Wednesday the council met to consider the applications for the chair of engineering, rendered vacant by the removal of Prof. Ewing to Cambridge. There were some 20 applicants, and from amongst them the council appointed Mr. T. Claxton Fidler, M.I.C.E., London.

International Telegraph Tariffs.—At a Cabinet Council held at Paris on Tuesday, President Carnot signed the Bill ratifying the telegraph tariffs fixed at the International Telegraph Conference held in Paris on June 21 last, and the special agreements concluded with Germany, Russia, Belgium, Luxemburg, the Netherlands, and Switzerland.

Electric Tramway for Naples.—The Municipal Government of Naples have authorised the construction of an electric tramway from the Museo to the Capodimonte at Naples. Mr. Von Buch, of Messrs. Foote and Von Buch, has obtained a concession from the Italian Government to work the line on the series system, and the firm are now undertaking the contract.

Professor Helmholtz.—News from Berlin says that on the seventieth birthday of Prof. Helmholtz, the celebrated physicist, which falls on the 31st of August, his numerous friends and admirers have determined to present him with some mark of their esteem. The details are to be settled by a committee, consisting of Profs. Hofmann, Du Bois-Reymond, Virchow, and others.

Exhibition of Meteorological Instruments.—The Royal Meteorological Society has arranged to hold, at 25, Great George-street, Westminster, on March 17th to 20th, an exhibition of meteorological instruments, as well as photographs and drawings possessing meteorological interest. Lists of articles intended for exhibition must be with the secretary not later than the 10th February.

Making Sure.—Most people have a horror of being buried alive, and certainly the stories that occasionally crop up on the subject are sufficiently marrow-freezing. But perhaps the idea of cremation whilst in a trance is more disquieting still. We notice that the late Miss Emma Abbott, of New York, directs in her will that her body shall be tested electrically for any signs of life prior to being cremated.

Ship Lighting.—A large steam yacht of 700 tons was this week launched by Messrs. Ramage and Ferguson, of Leith, for Lord Ashburton. She is named "The Ladye Mabel," and is lighted electrically. Lord Ashburton's pleasant country seat, The Grange, Northington, near Alresford, Hants, has been most satisfactorily lighted by electricity for some years past, the new illuminant having been introduced by his Lordship's father.

Edinburgh Exhibition.—Lord Stormonth-Darling has granted a petition by the liquidator of this exhibition for the rectification of the list of contributories by the deletion of the names of those persons who agreed to subscribe to the guarantee fund, but who did not become members of the association, they having subscribed to the fund before the association was formed. It is reported that the guarantors have paid up £24,854, leaving £1,703 still due.

Dublin.—At the meeting of the Corporation on the 12th inst., the report of the Electric Light Committee on the subject of the tenders received for the lighting of the city was to have come up for confirmation. Before, however, the subject was reached, intimation was received by the Lord Mayor, who presided, of the sudden death of a member of the Council (Alderman John O'Connor), whereupon the meeting adjourned for a week as a mark of respect to the memory of the deceased.

Exeter.—A ratepayers' meeting was held last week to protest against the proposal of the Town Council to apply for a provisional order to enable them to supply the electric light, on the ground that the Council's action was more in the nature of opposition to the local company than *bonâ fide.* Resolutions were passed to the effect that it was undesirable for the Council at present to undertake the supply of electricity, and also that a memorial on the subject should be presented to the Board of Trade.

Death.—We have to record the death of a very old postal employé in the person of Mr. Wm. Stainsby, postmaster of Hartlepool, who succumbed to an attack of paralysis on Sunday last at the age of 56. Originally the representative of the British, Irish, and Magnetic Telegraph Company for many years, he, on the transference of the telegraphs to the Government in 1870, became telegraphic superintendent at West Hartlepool, and about 12 years since was appointed postmaster at West Hartlepool.

Blotting Pads.—Messrs. Hudson and Kearns, of 83, Southwark-street, S.E., have sent us one of their blotting pads, with date indicator and diary combined. Speaking from some years' experience, we can strongly recommend these very handy adjuncts of the office table.—We have also received a useful pad from Messrs. R. E. Crompton and Co., which, besides absorbing superfluous ink, contains a calendar, memoranda slips for each day, and some particulars as to weights and measures, interest tables, etc.

Electrical Advertisement.—By an odd error the description of the electrical music-hall sign was given last week as being upon the "Pavilion," instead of, as it should be, on the "Trocadero." The large sign has been erected in the form of this word at considerable expense, and the colours are changed frequently by an automatic arrangement. There have been other large electric signs put up, as, for instance, the "Tit-Bits" sign; but, so far as we are aware, there is no such automatic changing advertisement erected elsewhere.

Commissioners of Sewers.—At their meeting on Tuesday, the Commissioners referred questions connected with the City lighting to the Streets Committee, and empowered them to obtain the assistance of Mr. Preece. It was decided to obtain the services of a permanent electrical engineer to superintend the laying of mains. A letter from the Brush Company as to laying mains from Southwark Bridge to the Guildhall, and from Blackfriars Bridge to the Mansion House, was alluded to as evidence that the lighting is about to be undertaken seriously.

Glasgow.—At the last meeting of the Town Council it transpired that the Bazaar Committee had had under consideration a report by Mr. Cook recommending an expenditure of about £1,660, which would obviate the risk of the Bazaar and the City Hall being left in comparative darkness in the event of a breakdown of the present plant. The committee, in view of the fact that the Corporation were to undertake the electric lighting of the city under the electric lighting provisional order, declined to adopt the recommendation. It was stated at the Council meeting that it might be four or five years before the Corporation were able to undertake the lighting of the city by electricity.

The Telephone in Manchester.—We are informed that the Mutual Telephone Company will open the first section of their Manchester Telephone Exchange for traffic early in February, and that they hope to begin work in Liverpool soon afterwards. Orders for between 1,600 and 1,700 wires have been already obtained in Manchester, and a considerable number of orders have also been booked in Liverpool. The company hold out the inducement of a lower rental combined with a better service. They will employ metallic circuits, and devote special attention to ensuring rapid connections. The general manager is Mr. A. R. Bennett, who has had wide and varied experience in telephone work.

City and South London Railway.—Last week the weather was all in favour of this line, and consequently more passengers desired to be carried in a given time than could be dealt with, hence there was some crowding at the City station. Given slush and fog, and the traffic receipts will go up by leaps and bounds. While we wish the railway in question all success, however, we would rather not make general deductions from the above fact. The company have deposited a Bill for their Islington extension, and seek power to raise £660,000 additional capital, with further borrowing powers not exceeding £220,000. The extension is to be carried out within five years. We notice that the traffic receipts on the City-Stockwell line last week amounted to £748.

St. Pancras.—Mr. Alderman T. E. Gibb, clerk of the St. Pancras Vestry, who is nothing if not energetic, has presented a report to the Electricity Committee on the subject of the holding of an exhibition of electrical appliances at the Vestry Hall with a view of informing the parishioners generally, who will before long be in a position to avail themselves of the electric light, on questions concerning the uses of electricity for lighting purposes and motive power, and as to the most efficient and economical way of obtaining fittings and appliances. Mr. Gibb has suggested a week next month in which to hold the exhibition, and that the expenses should be defrayed by the letting of space to exhibitors, and by imposing a small charge for admission. The committee have approved the proposal conditionally upon no part of the cost being charged to the rates.

Electric Bells.—We have received a very comprehensive catalogue (eighth edition) of the various designs in electric bells and accessory fittings manufactured by the General Electric Company, of 71, Queen Victoria-street, E.C. Those who want bells of any kind, whether for household or mining use, batteries, pushes, insulated wire, indicator boards, electric alarms, induction coils, insulators, toy motors, medical batteries and apparatus, magnetic telephones, gas lighters, and a hundred and one other requisites will find them all clearly illustrated, described, and priced in this catalogue. At the end of the book (it contains sufficient pages to be thus designated) are very complete instructions, with diagrams, for fixing and connecting electric bells, which are just what our readers in the country want, and we recommend them to obtain the catalogue.

Messrs. Appleton, Burbey, and Williamson, of 91, Queen Victoria-street, E.C., have sent us their catalogue, which is issued in a novel form this year. It consists of loose sheets numbered and arranged in a letter-box, which will no doubt preserve them better than the ordinary method of binding. Further, when any alteration or addition is necessary to the catalogue, the firm will merely issue a new sheet or sheets for insertion. The paper is of extra quality and the printing and illustrations very clear. In addition to the ordinary ink reproductions of the firm's switches and fittings, we find some very pretty illustrations of lamp shades, artistic electroliers and brackets. Information is also given as to electric bells, batteries, and fittings. We may safely say that Messrs. Appleton, Burbey, and Williamson do not intend to be left behind in the race for electrical work.

West Metropolitan Tramways Company.—This company, who were authorised in 1889 to construct additional tramways in Hammersmith, Chiswick, Acton, and

Ealing, have deposited a Bill asking Parliament to extend until August, 1893, the time originally granted for the construction of these lines. Among the reasons given for this request, the company state that they are desirous of reconstructing their existing system in such a manner that all the tramways may be worked by electrical power, but that, owing to many unavoidable difficulties, the local authorities have not yet agreed to allow electrical power to be adopted. To this delay on the part of the authorities in settling the terms upon which electricity may be used, the company ascribe their failure to raise the required additional capital necessary for the extensions, although the directors have used due diligence.

Bristol.—Mr. Preece has reported to the Town Council on a scheme for lighting Bristol. He suggests that the number of arc lamps to be used should be increased from 50 at 100ft. intervals to 100 at 50ft. apart, and the illuminating power of the incandescent lights (10,000) should be considerably increased. Mr. Preece states that on a recent visit to that city he was particularly struck with the brilliant light in the streets of Florence, where the lamps were placed in the centre of the thoroughfares. He proposes that this idea should be adopted in certain wide streets and spaces in Bristol. The entire cost of the installation will be about £50,000, and Mr. Preece thinks that the cost of maintenance will not be more than 12 per cent. beyond the cost of gas, and that when the light becomes general in private use, there will be a profit of 4 per cent. This report was considered by the Electric Lighting Committee of the Council last week. A further report from the city surveyor on a site for the central station has to be considered. It really looks as if Bristol were going ahead with this matter.

Electric Block Signals.—At the Inventors' Institute on Wednesday evening, Mr. J. Grover in the chair, Mr. C. E. Spagnoletti read a paper on "The Electric Locking and Block System in use on the City and South London Electric Railway." Two stations were fitted up in the room with levers and apparatus, and Mr. Spagnoletti showed how it was impossible for either levers to be moved until the train had passed the further station. In fact, the train announced its own arrival by depressing a multiplying lever set under the rails, which being in circuit with the locking apparatus enabled the signalmen to work the signal levers again. The system has been in use for some time on a particularly dangerous portion of the Metropolitan Railway, where the junction of the Great Northern and Midland lines in a tunnel, and the inability of the signalman to see anything because his box is in a recess of the wall, render the working very difficult—and so far with satisfactory results. We hope to illustrate and describe its working on the City and South London in another issue.

City Lighting.—A City paper has worked out the following statistics: "Now that the City is within measurable distance of getting the electric light, it is interesting to learn that the present public lighting bill of the City is rather less than £10,000 a year. The future cost with electric light will be rather more than £20,000. Roughly speaking, gas lamps, of which the probable candle-power is 40,000, are to be replaced by electric lamps of 800,000 c.p. There are now in each of the three divisions about 1,000 gas lamps. They will be replaced by a gross total of about 400 arc lamps and 1,000 glow lamps. For main thoroughfares arc lamps, costing for maintenance £26 each a year, will be used; and in smaller streets, lanes, and courts, glow lamps, costing each for maintenance £5 or £10 a year. The arc lamps have each a nominal candle-power of 2,000 candles, and they will be placed at intervals of about 250ft. Midway between two arc lamps the light will be 40 times greater than midway between two existing gas lamps of 10 candles each. For private lighting both companies will use the alternating-current system."

Sunderland.—At a meeting of the Electric Lighting Committee of the Corporation, held on Tuesday, the clerk submitted a list of suggested amendments from the solicitor on behalf of the Sunderland Gas Company and the Sunderland and South Shields Water Company to the Corporation's order for supplying electricity. He stated that he had sent the amendments to the London agents of the Corporation who drew the Bill. Their reply was that they could not advise the Corporation to concede the suggested amendments, inasmuch as, when the Electric Lighting Bill was before the Board of Trade last session, gas and water companies throughout the country were allowed to send in objections and amendments, which were all duly considered. A deputation from the gas and water companies having been admitted, the town clerk drafted a resolution to the effect that the Corporation as a public authority would agree to protect as far as they could the interests of all parties concerned, and that, if the deputation could induce the Board of Trade to accept their suggested amendments to the Bill, the Corporation would not feel called upon to oppose them. This was adopted.

An Indiarubber Ring.—A telegram from Boston (U.S.), dated Jan. 12, says: "It is rumoured here that a syndicate of Englishmen and Americans, with a capital of from four to five million dollars, is being formed for the purpose of buying up all the indiarubber in the world. It is said that the syndicate already possesses the monopoly of half the Para rubber, and that it intends to operate both in Great Britain and the United States." Later telegrams, dated New York, say that the above report is regarded there as an absurd invention. About 12 months ago the indiarubber manufacturers in England combined to raise the price of rubber goods to the wholesale houses about 10 per cent. The above report is believed to be a "feeler," sent out with a view to putting the price up again to the users. It cannot be ascertained that any Englishmen are in Boston engaged in forming any such syndicate as mentioned. A competent authority on the subject says that, on the contrary, the English are interested in the concessions granted by the Government of Liberia, where rubber is equal, if not superior, to that of Para, and that the working of the existing English company will probably check any such proceedings as are reported from Boston. The whole thing is regarded as an attempt to send up the price of rubber.

Detecting Flaws.—Captain De Place, of Paris, has devised an apparatus for detecting flaws in castings which he calls the "sciséophone." It was shown in action by the inventor at Charing Cross Hotel on Wednesday last. The apparatus consists of a small pneumatic tapper worked by the hand, and with which the piece of steel or iron to be tested is tapped all over. Connected with the tapper is a telephone with a microphone interposed in the circuit. Two operators are required, one to apply the tapper and the other to listen through the telephone to the sounds produced. These operators are in separate apartments, so that the direct sounds of the taps may not disturb the listener who is to detect flaws. The two, however, are in electrical communication, so that the instant the listener hears a false sound he can signal to his colleague to mark the metal at the point of the last tap. In practice the listener sits with the telephone to his ear, and so long as the taps are normal he does nothing. Directly a false sound is heard he at once signals for the spot to be marked. By this means Captain De Place claims that he is able not only to detect a flaw, but to localise it. Tests were made in the presence of Mr. Stirling, locomotive superintendent to the S.E.R., and several engineers and others, and flaws were localised by this method. On the other hand, however, it occasionally indicated a flaw in what proved to be sound metal, so that perfection has not apparently been reached.

Telegraphists' School of Science.—Mr. H. C. Fischer presided, on Wednesday, at the fourteenth annual distribution of medals, prizes, and certificates to students in this school, which took place at the General Post Office. Mr. J. C. Lamb, secretary of the Telegraph Department, and Mr. Ardron were also present, and Mr. W. H. Preece, F.R.S., distributed the prizes. According to the report of the school 40 per cent. of the certificates in technical telegraphy, granted by the City and Guilds Institute to the schools in the United Kingdom, were awarded to the students of this school, who also obtained two or three silver medals, with money prizes, offered for competition. Sixty-three per cent. of the certificates were first class. The successes in the pure science subjects, which are supplementary to the technical section, were also very numerous, and of an equally high standard. Mr. Preece complimented Mr. Slingo, principal of the school, and his staff on the continued success of the institution and dwelt forcibly upon the value of sound technical education among the general body of the staff in assisting the British Telegraph Administration in maintaining its pre-eminent position. The chairman observed that the fact that a higher technical knowledge is now demanded of a telegraphist than in years gone by, to enable him to successfully control the present delicate and complicated apparatus, weighed heavily with the authorities in determining the recent improvements in the status and pay of the telegraph staff.

The Telephone at Plymouth.—The following is an extract from the annual report of the Plymouth Chamber of Commerce: "The subject of telephonic signalling from ships to the shore has come in several forms and on frequent occasions before the Chamber and its committees. Permission has been obtained for the signalmen of the Breakwater Fort to telephone to the agents of the various lines of mail steamers the arrival of such steamers in the Sound when, owing to the thick weather, they are not observable from the shore. It has also been arranged for all Government offices in the port, including the office of the Queen's Harbourmaster, to be connected with the telephone exchange. The Western Counties and South Wales Telephone Company has generously placed a telephone in the rooms of the Chamber, thus giving to all members communication with the exchange. Permission has also been obtained for the telephone exchange to be connected with the coast guard signal station at Rame Head, with a view to merchant ships and ships of the Navy being reported, and signals exchanged with them, from that commanding position. The Admiralty have undertaken to provide coast guard signalmen for the purpose, subject to the necessary accommodation on the spot for the coast guardsmen and their families being provided. The signal station and wires have been erected, and but for the lack of suitable lodgings for the men near the Rame Head this important work would before this have been completed. The late Commander-in-Chief at Devonport, Admiral Sir William Dowell, and his successor, H.R.H. the Duke of Edinburgh, have both interested themselves warmly in this matter, and your chairman, with Mr. F. Phillips and Mr. Daggar, recently had an interview in London with Admiral Sir G. Tryon, commanding the Naval Reserves. The present temporary and seemingly trivial obstacle will, it is probable, be soon removed."

Ipswich.—At a special meeting of the Town Council last week the Paving and Lighting Committee presented a report, which stated that two companies had applied to the Board of Trade for provisional orders—namely, the Ipswich Electricity Supply Company, Limited, of 112, Belvedere-road, London, S.E.; and Laurence, Scott, and Co., Limited, Gothic Works, King-street, Norwich. The committee had gone carefully through the orders with a representative from each company, who had respectively undertaken that certain alterations should be made in the orders in accordance with the committee's suggestions. Subject to these alterations, the committee recommended the Council to give their approval or consent to both applications. A resolution in favour of the adoption of the report having been moved, Alderman Nicholson proposed an amendment to the effect that the Council should approve of the application of Laurence, Scott, and Co. only. A long discussion then ensued, in which several members spoke in favour of this firm, some from personal experience of their work, and eventually Alderman Nicholson's amendment was carried by 13 votes to seven. A motion was then carried in favour of opposing the application of the Ipswich Supply Company. The following resolution was also passed: "That it be an instruction to the Paving and Lighting Committee to make a representation to the Board of Trade with a view of securing such a modification of the draft order as will give the Urban Sanitary Authority power to acquire the undertaking after 10 years or such other term less than 42 years as they may be advised." This was further supplemented by a motion for providing in the order for the operation of a sliding scale, making the price charged for the supply of electricity subject to the dividends paid by the company. The Paving and Lighting Committee were empowered to employ such skilled or other assistance as they might require.

Derby.—We noticed in our last issue that the Town Council had instructed Sir F. Bramwell to report as to the town being lighted electrically. He has also been asked to draw up a scheme of sewage disposal, and the following is an extract from the somewhat amusing discussion which arose on the subject of Sir F. Bramwell's appointment: Mr. Foulds said the two things, the disposal of the sewage and the electric lighting, seemed so entirely different that, unless by some marvellous combination of genius, it seemed difficult to imagine that one man could successfully deal with them both. He had always looked upon Sir Frederick as a railway engineer, but he was surprised to find that he was going to deal with sewage, and still more when he found that he was to report upon electricity. Something had appeared in the papers about dealing with sewage by electricity. He did not know whether Sir Frederick Bramwell was the author of that. He should like to know whether Sir Frederick had that special knowledge which would qualify him to deal efficiently with this subject. The Mayor: I can assure you it is so. Mr. Foulds: Then I will second the motion. Mr. Alderman Bemrose said the Council were in a peculiar position, and immediate action was necessary. If some steps were not taken within a year and eight months, the Corporation would be obliged to transfer the matter to any company who chose to come to the town. It was therefore desirable to ascertain their true position, and, as Sir Frederick Bramwell was about to make a survey of the town, to obtain a report from him as to the best mode of dealing with the electric lighting question. It would be for the Council to decide what steps should be taken when they had his report, whether to go on with the matter themselves or hand it over to a private company, but the cost by the present arrangement would be considerably less than if Sir Frederick came down specially to deal with the electric lighting. The Mayor mentioned that Sir Frederick Bramwell had been engaged in connection with electric lighting at Bedford, Leeds, Knightsbridge, and other places, and said the committee wanted to obtain their information as cheaply as possible. They, therefore, came to the conclusion that when Sir Frederick was making a survey of the streets for sewage purposes he would probably undertake this work at a reasonable cost, and his representative had informed the committee that by taking the two schemes together they had obtained a considerable reduction in the fee. The proposition was then carried.

Edinburgh and Leith.—The town clerk of Leith has lodged with the Board of Trade objections by the Corporation of Leith against the Edinburgh electric lighting provisional order, and in support of certain amendments they desire to have inserted in the order, a number of facts and considerations are submitted. It is pointed out to the Board of Trade that both Corporations having jointly acquired the undertakings of the Edinburgh Gas Light Company and the Edinburgh and Leith Gas Light Company, and a commission, composed of 16 representatives from Edinburgh and seven from Leith, having been invested with powers for lighting Edinburgh and Leith, the rates of Leith are therefore pledged similarly with those of Edinburgh to provide a guarantee fund in the event of a deficiency of funds for payment of the annuities and the interest thereon, the interest of money borrowed, and the annual sums required to be transferred to the sinking and reserve funds. It is stated that in the order Edinburgh sought to enter into a competitive undertaking, which might prove prejudicial to the interests of the gas undertaking in which the two burghs are jointly interested; that the powers sought to be conferred upon the Corporation of Edinburgh by the proposed order should not be granted without ample provision being made for the protection of the burgh of Leith from any loss which might arise from the exercise of these powers by the Corporation of Edinburgh; that the Corporation of Leith protest in the strongest possible manner against the Corporation of Edinburgh, who have a majority on the Gas Commission, having the power to transfer their electric lighting undertaking to the Gas Commissioners, and so to cast the financial and other responsibilities and consequences of the undertaking upon funds in which the burgh of Leith and city of Edinburgh are equally interested, and that the proposed power should not be granted, but that a proviso should be inserted in the order to the effect that such transfer should not be made unless agreed to by the Corporation of Leith by resolution to be passed in manner provided by the Electric Lighting (Scotland) Act, 1890; and that, in view of the proposed introduction by the Corporation of Edinburgh of a competitive method of lighting, the proposed order should provide that if at any time prior to the Corporation of Leith agreeing to a transfer to the Gas Commissioners, the Corporation of Leith consider that the price of gas supplied is higher than it would have been put but for the introduction and supply of electric light by the Corporation of Edinburgh, the Corporation of Leith may from time to time make a representation to the Board of Trade that such is the case, and the Board of Trade may direct an enquiry by a referee into the truth of the representation, and if the referee find that the price of gas is higher by reason of the exercise of the powers of the order, he shall fix the extent to which it is so affected, and shall order a corresponding reduction of the price of gas within the burgh of Leith, the gross amount of such reduction to be recoverable from the Corporation of Edinburgh by the Gas Commissioners. The proposed amendments to give effect to the above objections are also submitted. A copy of the objections and the proposed amendments have been forwarded to the town clerk of Edinburgh.

Dover.—Since our last note on the Dover lighting another Council meeting has been held, at which the following discussion took place: The Mayor said that with respect to the electric light they had had a report from Mr. Timmis, and they were still waiting for further information from him. He might remind the Council that the Corporation had obtained a provisional order, either to enable the Corporation to supply the light themselves, or to lease the concession to a company. He thought that it was advisable, before deciding what they should do, to ascertain if it were possible to obtain terms for the undertaking to be taken up by some public company. He did not propose to ask them to enter into correspondence at once with any company as to the terms on which they would undertake the matter, but he thought that while they were waiting for Mr. Timmis's further report they might employ their time in collecting information from other towns which have obtained provisional orders. They knew that a great many towns had obtained provisional orders, and it would be well to ascertain what they were doing as to supplying electric light. He would therefore move that the town clerk be instructed to enquire from the authorities in the towns which had obtained provisional orders for supplying the electric light as to what they were doing in the matter. Councillor Brown said he had no objection to second that motion, because it abstained from the declaration of any policy; the enquiry could not do any harm, although the information that they should get might not be of any great value. He thought that having allowed the gas company to acquire rights in the town, they should carefully consider matters before they allow another company to acquire control of the streets for electric lighting. Councillor Pepper said he entirely agreed that they were not entering on a new policy. They had only two possible policies—namely, to supply the light themselves, or lease the undertaking. He thought that their best advice for the present was contained in a small word of five letters—delay. Before rushing into an expenditure of which they had no clear estimate, it was necessary that they should acquire more information. He understood that they were waiting for another report of Mr. Timmis, explanatory of the other. The Town Clerk: Yes. Councillor Peake said he should support the resolution, because it harmonised with what he stated a week ago. Since they last met, Mr. Timmis's report had been severely criticised by papers that were thoroughly acquainted with electric engineering, therefore it would be well to wait before doing anything more. He thought that if they applied to towns somewhat similar to Dover—for instance, Rochester, Leamington, and Cheltenham—they would do better than by applying to the larger towns. Councillor Bradley said he was glad that they were to gather further information, for when Mr. Timmis was there he was asked to mention a town where his proposals were in operation, but was unable to do so then. Perhaps he would do so in his supplementary report. He certainly should hesitate in deciding on any policy until they had further information, especially when they read in the papers that the City of London was handing over its electric light to a company. While agreeing to a great extent with Mr. Councillor Brown as to keeping the power in their own hands as far as possible, he thought it very desirable to be fortified with further information before taking action.

INSTITUTION OF ELECTRICAL ENGINEERS.

ADDRESS OF THE PRESIDENT, WILLIAM CROOKES, F.R.S.

ELECTRICITY IN TRANSITU: FROM PLENUM TO VACUUM.

INTRODUCTION.

Whilst steadily bearing in mind that I have the honour to address a society not only of physicists, but of electrical engineers, I shall not, I hope, be out of order in venturing to call your attention to a purely abstract phase of electrical science. Numberless instances show that pure research is the abundant source from which spring endless streams of practical applications. We all know how speculative enquiry into the influence of electricity on the nervous systems of animals led to knowledge of current electricity, and ultimately to the priceless possession of the telegraph and the telephone. The abstract study of certain microscopic forms of parasitic vegetable life has enabled us to give to fermented solutions of sugar the exact flavour and aroma of the most highly-prized wines, and probably, ere long, will put us in a position to increase at will the fertility of the soil. In a different direction the same class of abstract researches applied to medical science has brought us within measurable distance of the final conquest over a large class of diseases hitherto incurable; and without egotism I may, perhaps, be allowed to say that my own researches into high vacua to some extent have contributed to the present degree of perfection of the incandescence lamp. Surely, therefore, whilst eagerly reaping and storing the harvest of practical benefits, we must not neglect to scatter more seed for future results, perchance not less wonderful and valuable.

In another respect I deviate to some extent from the course taken by many of my predecessors. I am about to treat electricity, not so much as an end in itself, but rather as a tool, by whose judicious use we may gain some addition to our scanty knowledge of the atoms and molecules of matter, and of the forms of energy which by their mutual reactions constitute the universe as it is manifest to our five senses.

I will endeavour to explain what I mean by characterising electricity as a tool. When working as a chemist in the laboratory, I find the induction spark often of great service in discriminating one element from another, also in indicating the presence of hitherto unknown elements in other bodies in quantity far too minute to be recognisable by any other means. In this way, chemists have discovered thallium, gallium, germanium, and numerous other elements. On the other hand, when examining electrical reactions in high vacua, various rare chemical elements become in turn tests for recognising the intensity and character of electric energy. Electricity, positive and negative, effect respectively different movements and luminosities. Hence the behaviour of the substances upon which electricity acts may indicate with which of these two kinds we have to deal. In other physical researches both electricity and chemistry come into play simply as means of exploration.

In submitting to you certain researches in which electricity is used as a tool, or as a means of bringing within scope of our senses phenomena that otherwise would be unrevealed, I must for a moment recall to your minds the now generally accepted theory of the constitution of matter.

KINETIC THEORY OF GASES.

Matter, at its ultimate degree of extension, is conjectured to be not continuous, but granular. Maxwell illustrates this view as follows: To a railway contractor driving a tunnel through a gravel hill, the gravel may be viewed as a continuous substance. To a worm wriggling through gravel it makes all the difference whether the creature pushes against a piece of gravel or directs its course between the interstices. To the worm, therefore, gravel seems by no means homogeneous and continuous.

With speculations as to the constitution of liquid and solid matter I need not trouble you, but will proceed at once to the third or gaseous state of matter.

The kinetic theory of gases teaches that the constituent molecules dart in every possible direction with great but continually varying velocities, coming almost ceaselessly in mutual collision with each other.* The distance each molecule traverses without hitting another molecule is known as its *free path*; the average distance traversed without collision by the whole number of molecules of a gas at any given pressure and temperature is called the *mean free path*. The molecules exert pressure in all directions, and are only restrained by gravitation from dissipating themselves into space. In ordinary gases, the length of the mean free path of the molecules is exceedingly small compared with the dimensions of the vessel, and the properties we then observe are such as constitute the ordinary gaseous state of matter, which depend upon constant collisions. But if we greatly reduce the number of molecules in a given extent of space the free path of the molecules under electric impulse is so long that the number of their mutual collisions in any given time in comparison with the number of times they fail to collide may be disregarded. Hence, the average molecule can carry out its own motions without interference. When the mean free path becomes comparable to the dimensions of the containing vessel, the attributes which constitute gaseity shrink to a minimum, the matter attains the ultra-gaseous or "radiant" state, and we arrive at a condition where molecular motions under electrical impulse can easily be studied.

The mean free path of the molecules of a gas increases so rapidly with progressive exhaustion, that whilst that of the molecules of air at the ordinary pressure is only $\frac{1}{10000}$th of a millimetre, at an exhaustion of a hundred-millionth of an atmosphere—a point (which, with present appliances, is easy to attain) corresponding to the rarefaction of the air 90 miles above the earth's surface—the mean free path will be about 30ft.; whilst at 200 miles above the earth it will be 10,000,000 miles, and millions of miles out in the depths of space it will become practically infinite. I could go on speculating in spite of Aristotle, who said: "Beyond the universe there are neither space, nor vacuum, nor time."

In discussing the motions of molecules we have to distinguish the *free* path from the *mean free path*. Nothing is yet known of the *absolute* length of the free path nor of the *absolute* velocity of a molecule. For anything we can prove to the contrary, these values may vary almost from zero to infinity. We can deal only with the *mean* free path and the *mean* velocity.

THE VACUUM PUMP.

As most of the experiments I put before you to-night are connected with high vacua, it is not out of place to refer to the pump by means of which these tubes are exhausted. Much has been said lately in recommendation of the Geissler pump and its many improvements, but I am still strongly in favour of the Sprengel, as with it I have obtained greater exhaustion than with any other. I should like to point out that the action does not stop when we cease to see air specks passing down the tubes, but continues long after this point has been passed. Neither is the non-conducting vacuum, so easily obtained by the Sprengel pump, due in any way to the presence of mercury vapour, since non-conduction can be obtained just as rapidly when special precautions have been taken to keep mercury vapour out of the tubes.

One of the great advantages of the Sprengel pump over all others lies in the fact that its internal capacity need not exceed a few cubic centimetres, and there is, therefore, much less wall surface for gases to condense upon. I have brought the very latest modification of this form of pump here to-night, and you will have an opportunity of seeing it in action and of measuring with the McLeod gauge the rarefaction it produces.*

---

* I speak of "collisions," as these are the generally accepted *substrata* of the kinetic theory. But Prof. Silvanus P. Thompson reminds me that Boltzmann some years ago proposed a modification of the kinetic theory which to me seems a vast improvement on the somewhat bald notion of molecular collisions. According to Boltzmann's view, in a so-called "collision" the molecules do not actually bounce against one another, but merely fly round in two interlocking hyperbolic paths. The effect, for all external purposes, will be the same as if they collided, because of the extreme minuteness of the curved part of the paths. The gain in thus regarding the matter is that such hyperbolic paths are quite consistent with obedience to the ordinary laws of gravitational attraction, whereas the collision theory needs for its explanation that when molecules come very near together they should exhibit a repulsion varying inversely as the fifth power of the distance between them.

THE PASSAGE OF ELECTRICITY THROUGH RAREFIED GAS.

The various phenomena presented when an induction spark is made to pass through a gas at different degrees of exhaustion point to a modified condition of the matter at the highest exhaustions. Here are three exactly similar bulbs, the electrodes being aluminium balls, and the internal pressures being respectively 75 mm., 2 mm., and 0·1 mm. If I pass the induction current in succession through the bulbs, you will perceive in each case very different luminous phenomena. Here is a slightly exhausted tube, Fig. 1, like the first in the series just exhibited (75 mm.), the induction spark passes from one end to the other, A B, and the luminous discharge is seen as a line of light, acting as a flexible conductor. Under the tube I have an electro-magnet, C, and on making contact the line of light dips in the centre down to the poles of the magnet, and then rising again proceeds in a straight line. On reversing the current the line of light curves upwards. Notice that the action of the magnet in this case is only local.

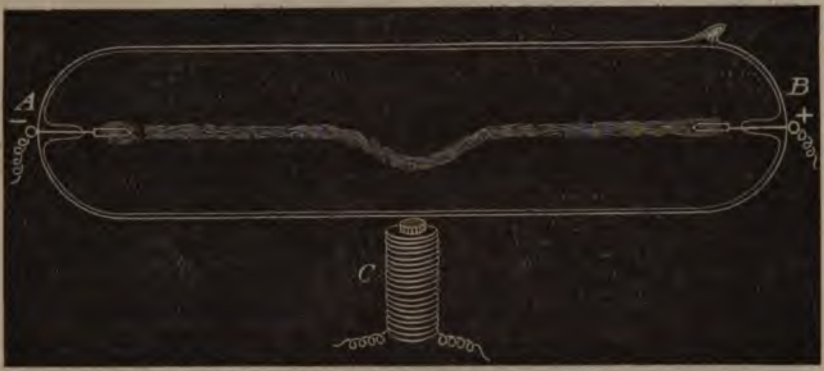

FIG. 1.—P. = 75 mm.

In a highly-exhausted tube the action is quite otherwise. Such a tube is before you, Fig. 2, and in it I have carried the exhaustion to a high point (0·1 mm.). I pass the induction current and you perceive the electrified molecules, like the line of light in the first tube, also move in straight lines, and make their path apparent by impinging on a phosphorescent screen, D E. If, however, I submit them to the action of a magnet, C, their behaviour is different. The line dips down to F, but does *not* recover itself.

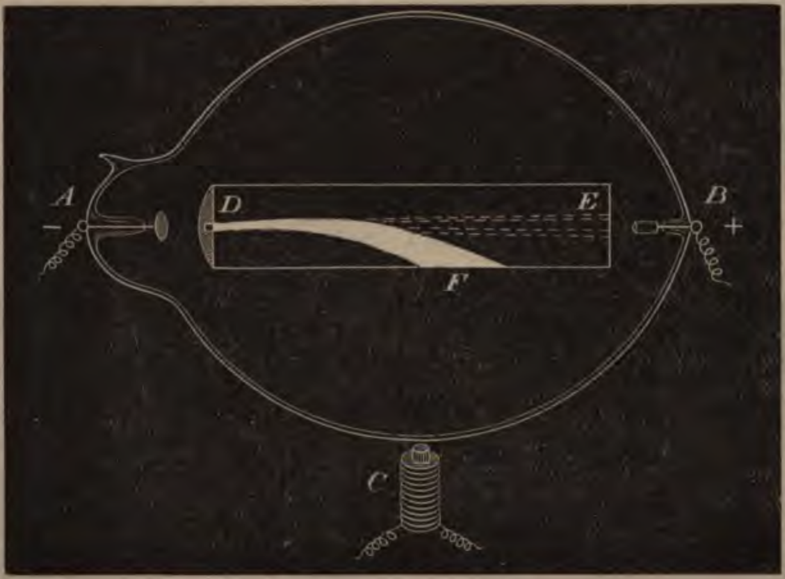

FIG. 2.—P. = 0·1 mm.   = 131·5 M.

It seems that in the tube first shown we have to do with the average behaviour of the molecules of gas in its totality. In the second case, where the gas has been greatly attenuated, we are merely concerned with the behaviour of the individual molecules of which it was originally composed.

---

* My measurements of high vacua have all been taken with the beautiful little gauge devised by Prof. McLeod. Unmerited discredit has recently been cast on this gauge, the principal fault alleged being its inability to distinguish between the tension of the permanent gas and that of the mercury vapour present. Now, it is evident that under ordinary circumstances the tension of mercury vapour may be disregarded, as it will be the same on both sides of the gauge, and it will be only in cases where no mercury is present on one side of the gauge that a slight error is introduced. It is, however, very difficult to devise and successfully experiment with apparatus in which a trace of mercury vapour shall not enter, and it is not likely that an experimentalist who would be working with such mercury-free apparatus would attempt to use the gauge without remembering that in this special case the indications would be incorrect. To use the McLeod gauge requires much patience, and some amount of experience, but I have always found it trustworthy to register exhaustions far beyond the millionth of an atmosphere. I can adduce circumstantial evidence of the accuracy of its readings at these high vacua. In the year 1881 I read a paper before the Royal Society on "The Viscosity of Gases at High Exhaustions" (*Phil. Trans.*, 1881, p. 387), and illustrated my results in three large diagrams, on which I plotted the experimental results obtained at rarefactions up to the 0·02 millionth of an atmosphere, giving curves comparing the decrease in viscosity with that of the repulsion resulting from radiation, at the different pressures. Now these curves, in the case of air for instance, are perfectly regular and uniform in their falling off, and it is evident that this could not have been the case unless the abscissæ representing viscosity and the ordinates representing pressure were equally accurate. I am satisfied that, within narrow limits, the abscissæ of viscosity are correct to the highest point, and the conformity of experiment to theory in the shape of these curves is a conclusive proof that, at as high an exhaustion as 0·02 M., the McLeod gauge is to be trusted to give accurate results within 2 per cent. of the truth. To give some idea what these high exhaustions mean I may mention that the highest measured exhaustion—0·02 M.—bears the same proportion to the ordinary pressure of the atmosphere that a millimetre does to 30 miles, or in point of time, that one second bears to 20 months.

The Stratified Discharge.

When the gas is rarer than is necessary to give the flexible line of light, as shown in the first experiment, the luminosity is plainly discontinuous, or, as it is termed, stratified.

A very good illustration of this fact may be taken from the moving crowd in any much frequented street, say Fleet-street. If at some time when the stream of traffic runs almost equally in both directions, we take our stand at a window from which we can overlook the passing crowd, we shall notice that the throng on the footway is not uniformly distributed, but is made up of knots, we might almost say blocks, interrupted by spaces which are comparatively open. We may easily conceive in what manner these knots or groups are formed. Some few persons walking rather more slowly than the average rate slightly retard the movements of others whether travelling in the same or in an opposite direction. Thus a temporary obstruction is created. The passengers behind catch up to the block and increase it, and those in front, passing on unchecked at their former rate, leave a comparatively vacant space. If a crowd is moving all in the same direction the formation of these groups becomes more distinct. With vehicles in crowded streets, the result, as everyone may have remarked, will be the same.

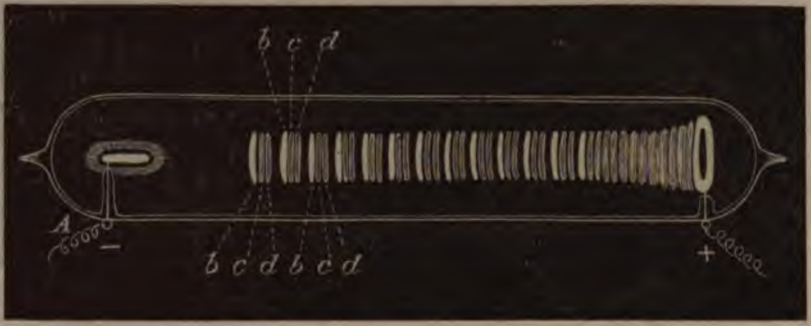

Fig. 3.—P. = 2·0 mm. = 2630·0 M.

Hence mere differences in speed suffice to resolve a multitude of passengers into alternating gaps and knots.

Instead of observing moving men and women, suppose we experiment on little particles of some substance, such as sand, approximately equal in size. If we mix the particles with water in a horizontal tube and set them in rhythmical agitation, we shall see very similar results, the powder sorting itself with regularity into alternate heaps and blank spaces.

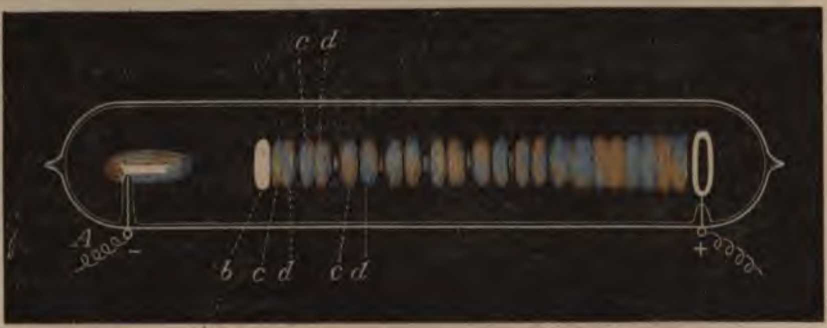

Fig. 4.—P. = 2·0 mm. = 2630·0 M.

If we pass to yet more minute substances we observe the behaviour of the molecules of a rarefied gas, when submitted to an induction current. The molecules here are free, of course, from any caprice, and simply follow the law I seek to illustrate, and though originally in a state of rampant disorder, yet under the influence of the electric rhythm they arrange themselves into well-defined groups or stratifications; the luminosities show where arrested motion with concomitant friction occurs, and the dark intervals indicate where the molecules travel with comparatively few collisions.

Parti-coloured Stratifications.

As another illustration of stratifications in a moderately exhausted tube (P. = 2 mm.), I will take the case of hydrogen prepared from zinc and sulphuric acid after being passed through various purifying agents, dried in the usual manner, and exhausted with a mercury pump, Fig. 3. I pass the induction current, and we see that the stratifications are tri-coloured, blue, pink, and grey. Next the negative pole, A, is a luminous layer, then comes a dark interval or Faraday's dark space (see below), and after this are the stratifications, the front component (*b*) of each group blue, the next (*c*) pink, and the third (*d*) grey. The blue discs are somewhat erratic. At a certain stage of exhaustion all the blue components of the stratifications suddenly migrate to the front, forming one bright blue disc, and leaving the pink and grey components by themselves. The tube before you, Fig. 4, is at this particular stage of exhaustion, and on passing the current you observe the blue disc only (*b*) is in front. When the tube contains a compound gaseous residue of this kind, the form of stratifications can be very considerably altered by varying the potential of the discharge. This alteration in the forms of stratification was first pointed out by Gassiot (1865, "B.A. Abstracts," p. 15), who gave very full descriptions and drawings of the alterations produced by putting in resistances of various lengths of distilled water. That the alteration depends simply upon the difference of potential the following experiment pretty clearly shows: Here is a tube, giving on my coil the coloured stratification usually attributed to the presence of residual hydrogen, but which I find is due to a mixture of hydrogen, mercury, and hydrocarbon vapours. Now, by altering the brake so as to produce frequent discharges of lower potential, you see the stratifications gradually change in shape and become all pink; again, altering the brake so as to send less rapid discharges at a much higher potential, once more we get the coloured stratifications. When in this state, if we introduce a water resistance into the circuit so as to damp down the potential, exactly the same thing happens. The blue disc is caused by mercury; its spectrum is that of mercury only, without even a trace of the bright red line of hydrogen. Experiments not yet finished make it very probable that the pink discs are due to hydrogen, and that the grey discs indicate carbon. The tube you have just seen contains nothing but hydrogen, mercury, and a minute trace of carbon; but with all the resources at my command I have not been able to get hydrogen quite free from impurity. Indeed, I do not think absolutely pure hydrogen has ever yet been obtained in a vacuum tube. I have so far succeeded as to completely eliminate the mercury, and almost completely to remove the trace of carbon. On the table is such a tube giving uniformly pink stratifications and showing no blue or grey discs with any potential of current.

THE DARK SPACE.

After the stratification stage is passed we come to a very curious phenomenon, the so-called "dark space." Studying electrical phenomena in gases, in the year 1838, Faraday[*] pointed out a break in the continuity of the luminous discharge separating the glow of the positive electrode from that of the negative. This he called "the dark space." It is seen in tubes containing gas only slightly rarefied, as in this tube, Fig. 5 (P. = 6 mm.), where you will observe that the positive glow, extending as a pink streak from the positive electrode, B, ends about 10 millimetres before the spot of blue light, C, representing the negative glow. This gap, or non-luminous hiatus, D, is Faraday's "dark space." Separating the negative glow from its electrode is another space. In this tube it is so small that the glow appears to be in actual contact with the electrode, but on exhausting a little further it rapidly separates; and in the next tube, Fig. 6, containing air at a little less pressure (P. = 3 mm.) this dark space, E, has extended so as to remove the negative glow about four millimetres from the electrode, A. It is with this second dark space that I particularly wish to deal to-night. Therefore I shall refer to it as the "dark space," meaning always that in the negative glow.

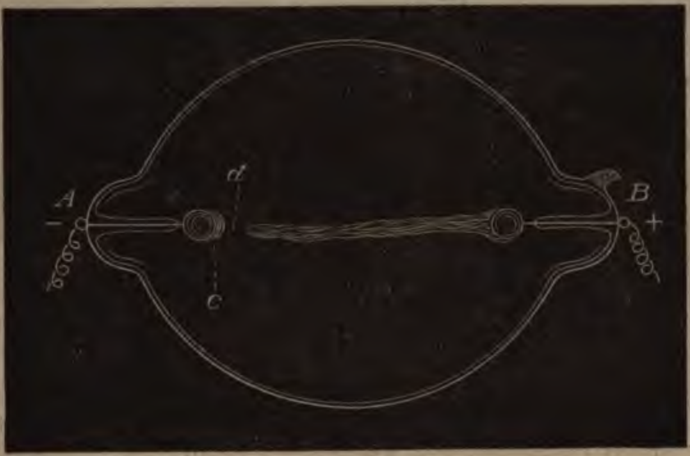

FIG. 5.—P. = 6·0 mm.

In the experiment just shown with hydrogen stratifications the contents of the tube under the electric discharge still obey the laws following from the average properties of an immense number of molecules moving in every direction with velocities of all conceivable magnitudes. But if I continue exhausting, the dark space, E, round the negative pole, A, becomes visible, grows larger and larger, and at last fills up the entire tube. The molecules at this stage are in a condition different from those in a less highly exhausted tube. At low exhaustions they behave as gas in the ordinary sense of the term, but at these high exhaustions, under electric stress, they have become exalted to an *ultra-gaseous* state, in which very decided properties, hitherto masked, come into play.

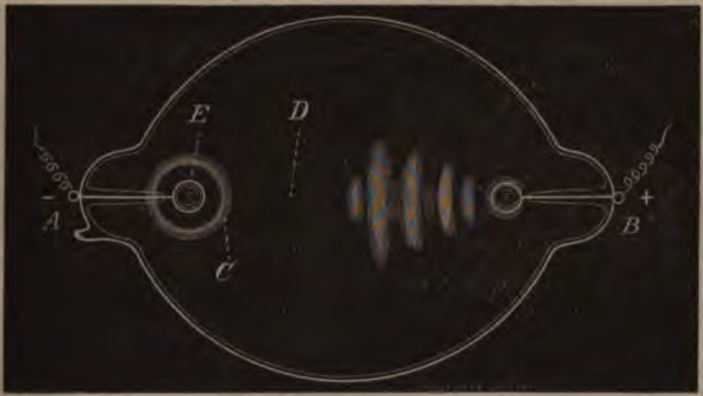

FIG. 6.—P. = 3·0 mm.

The radius of the dark space varies with the degree of exhaustion, with the kind of gas in which it has been produced, with the temperature of the negative pole, and to a less extent with the intensity of the spark.

It has been erroneously assumed that I ever said the thickness of the "dark space" represents the mean free path of the molecules in their ordinary condition, and it has been pointed out that the radius of the dark space is decidedly greater than the calculated mean free path of the molecules. I have taken accurate measurements of the radius of the dark space at different pressures, and compared it with the calculated mean free path of the gaseous molecules at corresponding pressures when not under the influence of electrical energy, and I find that they do not bear a constant relation one to the other. The length of the dark space is not 20 times the mean free pass, as some have estimated, but a gradually increasing multiple must be taken as the exhaustion becomes greater.

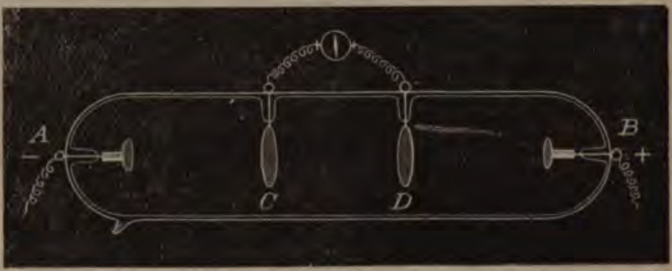

FIG. 7.

EXPLORATION WITH IDLE POLES.

Wishing to learn something of the electrical condition of the matter within and without the dark space, I made a tube, Fig. 7, having besides the positive and negative terminals, A B, two extra intermediate poles, C and D; the tube showed that when the exhaustion was such that both the idle poles were outside the dark space, on passing the current through the tube, there was a considerable difference of potential between them when measured on the galvanometer. If the exhaustion was carried so high that one of the extra poles was just on the border of the dark space, then no current passed between them. When the exhaustion was still further increased so as to enclose one of the extra poles fully in the dark space, again there was a great difference of potential between them, but the direction was reversed, the pole at highest potential now being the one formerly at lowest potential.

---

[*] "Experimental Researches in Electricity," 1838, par. 1,544.

When the dark space has been further explored by means of a movable negative pole, I found that the effects did not depend essentially on the exhaustion, and were really due to the position occupied by the extra poles with regard to the dark space.

These phenomena are difficult to understand from mere description, and the experiments themselves are not easy to carry out so as to be visible to many at a time. I have here, however, a working model of an apparatus which will make these puzzling indications clear to all.

A cylindrical tube, Fig. 8, *a*, *b*, and *c* (P. = 0·25 mm.), furnished with the usual poles, A B, at the ends, has two extra or idle poles near together at C and D. The pole A is movable along the axis of the tube, so that when exhausted the dark space can be brought to any desired position with respect to the idle poles, C and D. The shading and + and − marks roughly show the distribution of positive and negative electricity inside the tube. I start with the negative pole, A, as far as possible from either idle pole, Fig. 8, *a*. Turning on the coil you see the dark space surrounding the pole A, and the idle poles quite outside.

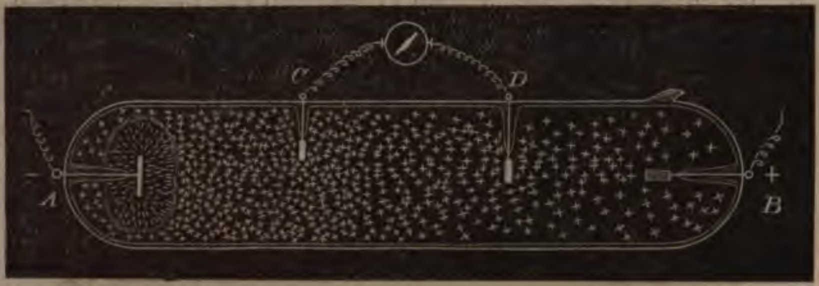

FIG. 8*a*.—P. = 0·25 mm. = 330·0 M.

The shading shows that each idle pole is in the positive area, and on testing with a gold leaf electroscope it will be seen that each is charged with positive electricity. But the shading also shows more positive at C than at D, and on connecting C and D with a galvanometer the needle indicates a rush of current from C to D, D being negative to C.

The dark space is next brought to such a position that the pole C is well within it, Fig. 8, *b*. A change has now come over the indications. The galvanometer shows a reverse current to that which was seen on the former occasion. C is now negative and D positive, but the gold leaves still tell us both poles are positively electrified.

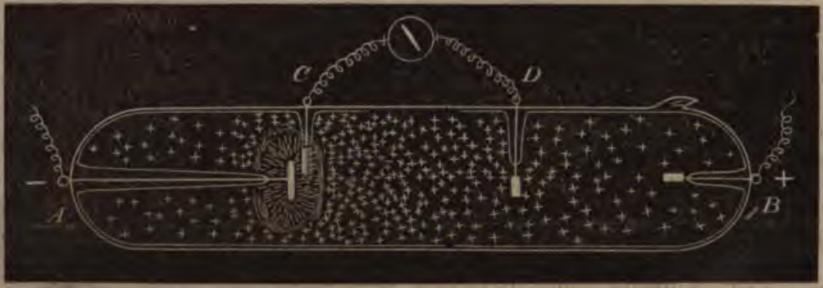

FIG. 8*b*.—P. = 0·25 mm. = 350·0 M.

At a certain position of the dark space, when its edge is on the pole C, Fig. 8, *c*, a neutral state is found at which the gold leaves still show strongly positive electrifications, and no current is seen on the galvanometer. The curves below, Fig. 8, *c*, roughly show the rise and fall of negative and positive current at different parts of the tube, whilst the potential curve keeps positive.

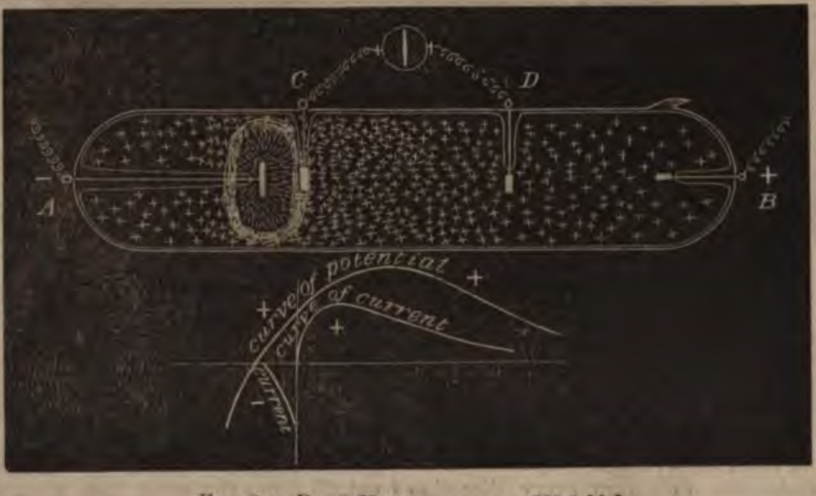

FIG. 8c.—P. = 0·25 mm. = 330·0 M.

When a substance that will phosphoresce under electrical excitement is introduced into the tube, the position of greatest luminosity is found to be at the border of the dark space, just where the two opposing armies of negative and positive atoms meet in battle array and recombine.

Later on I shall refer to this phenomenon in connection with the phosphorescence of yttria.

RADIANT MATTER.

By means of this tube, Fig. 9, I am able to show that a stream of ultra-gaseous particles, or radiant matter, does not carry a current of electricity, but consists of a succession of negatively electrified molecules whose electrostatic repulsion overbalances their electromagnetic attraction, probably because their speed along the tube is less than the velocity of light. The tube has two negative terminals, A A′, close together at one end, enabling me to send along the tube two parallel streams of radiant matter, rendered visible by impinging them through holes in a mica diaphragm on a screen of phosphorescent substance. It is exhausted to a pressure of 0·1 mm. I connect one of the negative poles, A, with the induction coil and the luminous stream darts along the tube from C to D parallel with the axis. I now connect the other negative pole, giving a second parallel stream of radiant matter. If these streams are in the nature of wires carrying a current they will attract each other, but if they are simply two streams of electrified molecules they will repel each other. As soon as the second stream is started you see the first stream jump away in the direction C E, showing strong repulsion, proving that they do not act like current carriers, but merely like similarly electrified bodies. It is, however, probable that were the velocity of the streams of molecules greater than that of light, they would behave differently and attract each other, like conductors carrying a current.

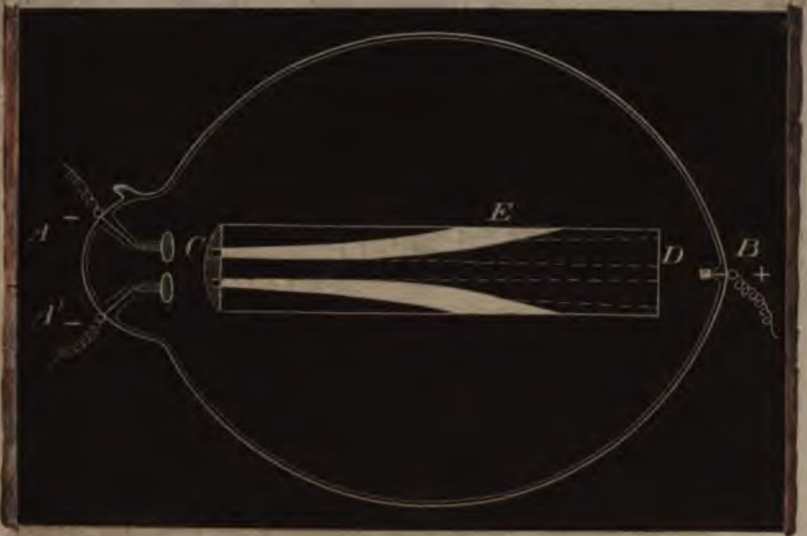

Fig. 9.—P. = 0·1 mm. = 131·5 M.

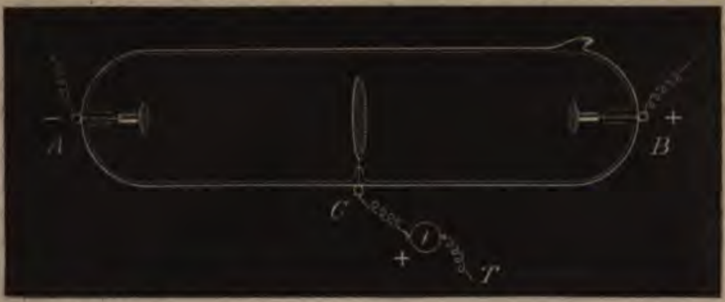

Fig. 10.—P. = 0·0001 mm. = 0·13 M.

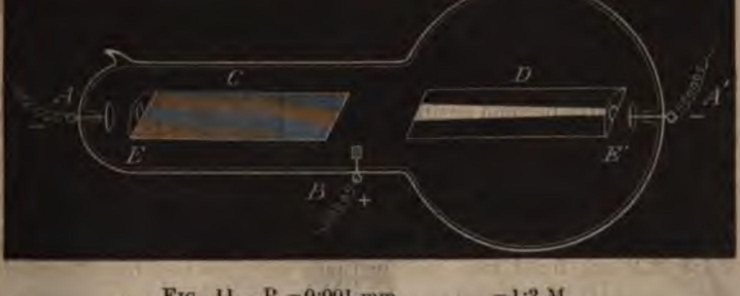

Fig. 11.—P. = 0·001 mm. = 1·3 M.

To ascertain the electrical state of the residual molecules in a highly-exhausted tube such as you have just seen, I introduced an idle pole or exploring electrode between the positive and negative electrodes in such a manner that the molecular stream might play upon it. The intention was to ascertain whether the molecules on collision with an obstacle gave off any of their electrical charge. In this experiment, Fig. 10 (P. = 0·0001 mm., or 0·13 M.*), it was found that an idle pole, C, placed in the direct line between the positive and the negative poles, A B, receiving in consequence the full impact of the molecules shot from the negative pole, manifested a strong *positive* charge. In a variety of other experiments made to decide this question the electricity obtained was always found positive on testing with the gold leaf or Lippman's electrometer, and when the idle pole was connected to earth through a galvanometer a current passed as if this pole were the copper element of a copper-zinc cell, indicating leakage of a current to earth, the idle pole being positive. If, instead of sending this current to earth, the wire was connected to the negative pole of the tube, a much more powerful current passed in the same direction.

---

* M. = one-millionth of an atmosphere.
1,000,000 M. = 760 mm. 1,000,000 M. = one atmosphere.

The Edison Effect.

An exactly parallel experiment has been made by Mr. Edison, Mr. Preece, F.R.S., and Prof. Fleming, using, instead of a vacuum tube, an incandescent lamp. They found that from an idle pole placed between the ends of the filament the electricity always flowed as if the pole were the zinc element of a copper-zinc cell; having repeated their experiments I entirely corroborate them. I get a powerful current in one direction from an idle pole placed between the limbs of an incandescent carbon filament, and one in the opposite direction from an idle pole in a highly-exhausted vacuum tube. This discrepancy was extremely puzzling, and I tested, with a similar result, very many experimental tubes made in different ways. The electricity obtained from an idle pole placed between the positive and negative terminals in a highly-exhausted tube was always strongly *positive*, and it is only recently that continued experiment has cleared the matter up.

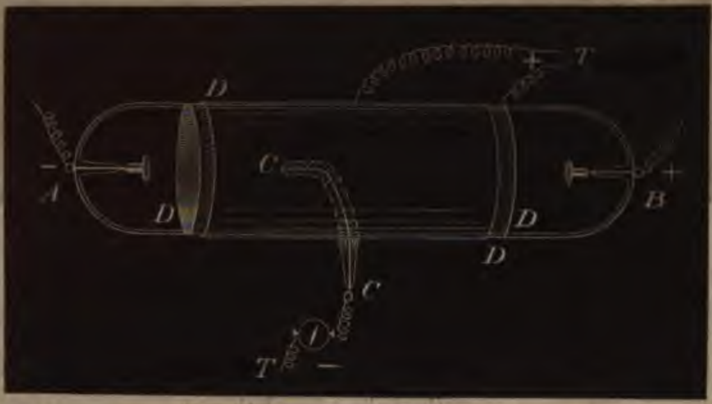

Fig. 12.—P. = 0·0001 mm. = 0·13 M.

Some of the contradictory results are due to the exhaustion not being identical in all cases. In my vacuum tubes the directions of current between the idle pole and the earth changes from negative to positive as the exhaustion rises higher. Testing the current when exhaustion is proceeding, there is a point reached when the galvanometer deflection—hitherto negative—becomes nil, showing that the potential at this point is zero. At this stage, the passage of a few more drops of mercury down the pump tube renders the current positive. This change occurs at a pressure of about 2 mm.

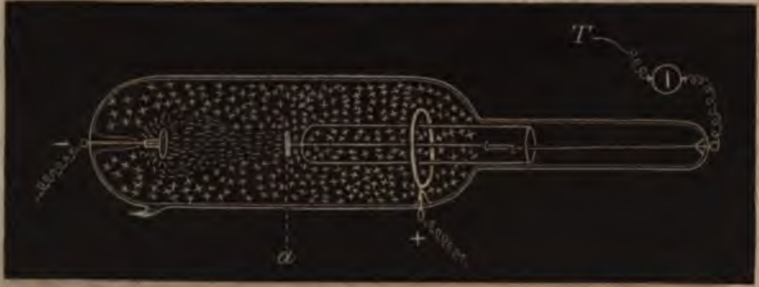

Fig. 13*a*.—P. = 0·0001 mm. = 0·13 M.

After this point is reached, when the induction current is passed through the tube, the walls rapidly become positively electrified, probably by the friction of the molecular stream against the glass, and this electrification extends over the surface of any object placed inside the tube. I will show you how this electrification of the inner walls of the tube acts on the molecular stream at high vacua. In this tube, Fig. 11 (P. = 0·001 mm. or 1·3 M.), are fixed two exactly similar phosphorescent screens, C and D; at one end of each is a mica gate, E E′, with a negative pole, A A′, facing it. One of the screens, C, is in the cylindrical part of the tube and close to the walls; the other, D, is in the spherical portion, and therefore far removed from the walls. On passing the current the screen D in the globe shows a narrow sharp streak of phosphorescence, proving that here the molecules are free to follow their normal course straight from the negative pole. In the cylindrical part of the tube, however, so great is the attraction of the walls that the molecular stream is widened out sufficiently to make the whole surface of the screen C glow with phosphorescent light.

If an idle pole, C C, Fig. 12 (P. = 0·0001 mm. or 0·13 M.), protected all but the point by a thick coating of glass, is brought into the centre of the molecular stream in front of the negative pole, A, and the whole of the inside and outside of the tube walls are coated with metal, D D, and "earthed," so as to carry away the positive electricity as rapidly as possible, then it is seen that the molecules leaving the negative pole and striking upon the idle pole C on their journey along the tube carry a negative charge, and communicate negative electricity to the idle pole.

This tube is of interest since it is the one in which I was first able to perceive how in my earlier results I always obtained a positive charge from an idle pole placed in the direct stream from the negative pole. Having got so far, it was easy to devise a form of apparatus that completely verified the theory, and at the same time threw considerably more light upon the subject. Fig. 13, *a*, *b*, *c*, is such a tube, and in this model I have endeavoured to show the electrical state of it at a high vacuum by marking a number of + and − signs. The exhaustion has been carried to 0·0001 mm., or 0·13 M., and you see that in the neighbourhood of the positive pole, and extending almost to the negative, the tube is strongly electrified with positive electricity, the negative atoms shooting out from the negative pole in a rapidly-diminishing cone. If an idle pole is placed in the position shown at Fig. 13, *a*, the impacts of positive and negative molecules are about equal, and no decided current will pass from it, through the galvanometer, to earth. This is the *neutral* point. But if we imagine the idle pole to be as at Fig. 13, *b*, then the positively electrified molecules greatly preponderate over the negative molecules, and positive electricity is shown. If the idle pole is now shifted as shown at Fig. 13, *c*, the negative molecules preponderate, and the pole will give negative electricity.

As the exhaustion proceeds, the positive charge in the tube increases, and the neutral point approaches closer to the negative pole, and at a point just short of non-conduction so greatly does the positive electrification preponderate that it is almost impossible to get negative electricity from the idle pole, unless it actually touches the negative pole. This tube is before you, and I will now proceed to show the change in direction of current by moving the idle pole.

I have not succeeded in getting the "Edison" current in incandescent lamps to change in direction at even the highest degree of exhaustion which my pump will produce. The subject requires further investigation, and, like other residual phenomena, these discrepancies promise a rich harvest of future discoveries to the experimental philosopher, just as the waste products of the chemist have often proved the source of new and valuable bodies.

PROPERTIES OF RADIANT MATTER.

One of the most characteristic attributes of radiant matter—whence its name—is that it moves in approximately straight lines, and in a direction almost normal to the surface of the electrode. If we keep the induction current passing continuously through a vacuum tube in the same direction, we can imagine two ways in which the action proceeds; either the supply of gaseous molecules at the surface of the negative pole must run short, and the phenomena come to an end, or the molecules must find some means of getting back. I will show you an experiment which reveals the molecules in the very act of returning. Here is a tube, Fig. 14, exhausted to a pressure of 0·001 mm. or 1·3 M. In the middle of the tube is a thin glass diaphragm, C, pierced with two holes, D and E. At one part of the tube a concave pole, A′, is focussed on the upper hole, D, in the diaphragm. Behind the upper hole, and in front of the lower one are movable vanes, F and G, capable of rotation by the slightest current of gas through the holes.

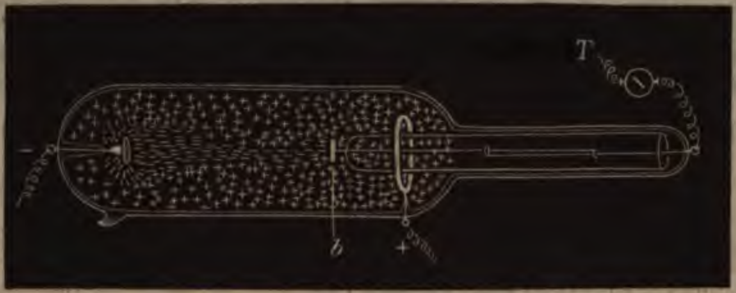

Fig. 13*b*.—P. = 0·0001 mm. = 0·13 M.

On passing the current with the concave pole negative, the small vanes rotate in such a manner as to prove that at this high exhaustion a stream of molecules issues from the lower hole in the diaphragm, whilst at the same time a stream of freshly-charged molecules is forced by the negative pole through the upper hole. The experiment speaks for itself, showing as forcibly as an experiment can show that so far the theory is right.

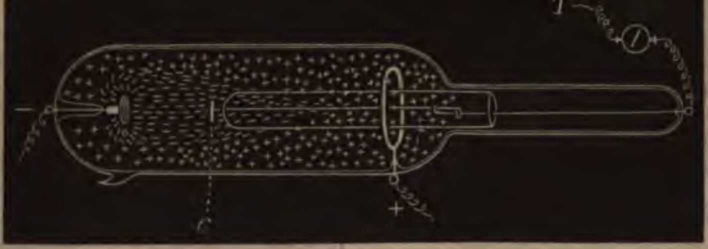

Fig. 13*c*.—P. = 0·0001 mm. = 0·13 M.

This view of the ultra-gaseous state of matter is advanced merely as a working hypothesis, which, in the present state of our knowledge, may be regarded as a necessary help to be retained only so long as it proves useful. In experimental research early hypotheses have necessarily to be modified, or adjusted, or perhaps entirely abandoned, in deference to more accurate observations. Dumas said, truly, that hypotheses were like crutches, which we throw away when we are able to walk without them.

RADIANT MATTER AND "RADIANT ELECTRODE MATTER."

In recording my investigations on the subject of radiant matter and the state of gaseous residues in high vacua under electrical strain, I must refer to certain attacks on the views I have propounded. The most important of these questionings are contained in a volume of "Physical Memoirs," selected and translated from foreign sources under the direction of the Physical Society (vol. i., part 2). This volume contains two memoirs, one by Hittorff on the "Conduction of Electricity in Gases," and the other by Puluj on "Radiant Electrode Matter and the So-called Fourth State. Dr. Puluj's paper concerns me most, as the author has set himself vigorously to the task of opposing my conclusions. Apart from my desire to keep controversial matter out of an address of this sort, time would not permit me to discuss the points raised by my critic; I will therefore only observe in passing that Dr. Puluj has no authority for linking my theory of a fourth state of matter with the highly-transcendental doctrine of four dimensional space.

Reference has already been made to the mistaken supposition that I have pronounced the thickness of the dark space in a highly-exhausted tube, through which an induction spark is passed, to be identical with the natural mean free path of the molecules of gas at that exhaustion. I could quote numerous passages from my writings to show that what I meant and said was the mean free path as amplified and modified by the electrification.* In this view I am sup-

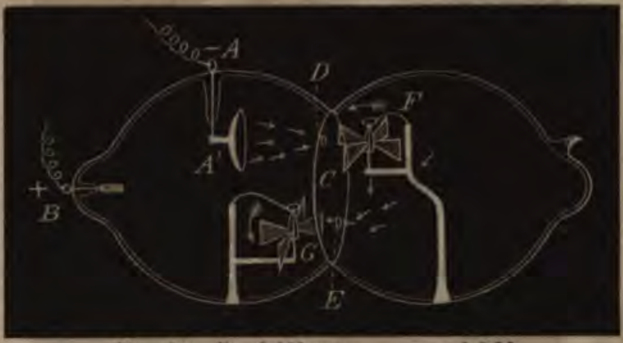

Fig. 14.—P. = 0·001 mm. = 1·3 M.

---

* "The thickness of the dark space surrounding the negative pole is the measure of the mean length of the path of the gaseous molecules between successive collisions. The electrified molecules are projected from the negative pole with enormous velocity, varying, however, with the degree of exhaustion and intensity of the induction current."—(*Phil. Trans.*, part i., 1879, par. 530).

"The extra velocity with which the molecules rebound from the excited negative pole keeps back the more slowly moving molecules which are advancing towards the pole. The conflict occurs at the boundary of the dark space, where the luminous margin bears witness to the energy of the discharge."—(*Phil. Trans.*, part i., 1879, par. 507.)

"Here, then, we see the induction spark actually illuminating the lines of molecular pressure caused by the excitement of the negative pole."—(R. I. Lecture, Friday, April 4, 1879.)

ported by Prof. Schuster,* who, in a passage quoted below, distinctly admits that the mean free path of an electrified molecule may differ from that of one in its ordinary state.

The greatest difference between Puluj and myself lies in his statement that† *"the matter which fills the dark space consists of mechanically detached particles of the electrodes which are charged with statical negative electricity, and move progressively in a straight direction."*

To these mechanically detached particles of the electrodes, 'of different sizes, often large lumps,"‡ Puluj attributes all the phenomena of heat, force, and phosphorescence that I from time to time have described in my several papers.

Puluj objects energetically to my definition "radiant matter," and then proposes in its stead the misleading term, "radiant electrode matter." I say "misleading," for while both his and my definitions equally admit the existence of "radiant matter," he drags in the hypothesis that the radiant matter is actually the disintegrated material of the poles.

Puluj declares that the phenomena I have described in high vacua are produced by his irregularly shaped lumps of radiant electrode matter. My contention is that they are produced by radiant matter of the residual molecules of gas.

Were it not that in this case we can turn to experimental evidence I would not mention the subject to you. On such an occasion as this controversial matter must have no place; therefore I content myself, at present, by showing a few novel experiments which demonstratively prove my case.

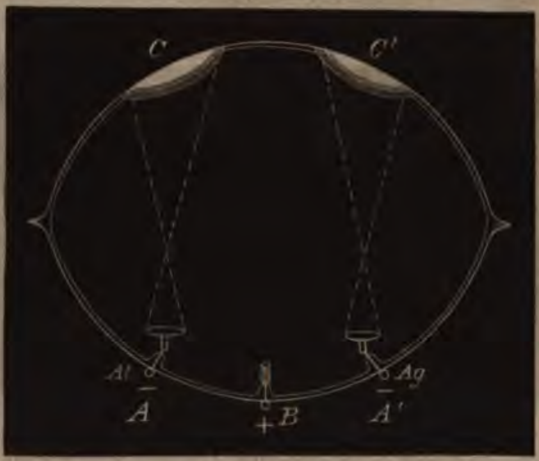

FIG. 15.—P. = 0·00068 mm. = 0·9 M

Let me first deal with the radiant electrode hypothesis. Some metals, it is well known, such as silver, gold, or platinum, when used for the negative electrode in a vacuum tube, volatilise more or less rapidly, coating any object in their neighbourhood with a very even film. On this depends the well-known method of electrically preparing small mirrors, etc. Aluminium, however, seems exempt from this volatility. Hence, and for other reasons, it is generally used for electrodes.

If, then, the phenomena in a high vacuum are due to the "electrode matter," the more volatile the metal used the greater should be the effect.§

Here is a tube, Fig. 15 (P. = 0·00068 mm., or 0·9 M.), with two negative electrodes, A A', so placed as to project two luminous spots on the phosphorescent glass of the tube. One electrode, A', is of pure silver, a volatile metal, the other, A, is of aluminium, practically non-volatile. A quantity of "electrode matter" will be shot off from the silver pole and practically none from the aluminium pole; but you see that in each case the phosphorescence, C C', is identical. Had the radiant electrode matter been the active agent the more intense phosphorescence would proceed from the more volatile pole.

A drawing of another experimental piece of apparatus is shown in Fig. 16. A pear-shaped bulb of German glass has near the small end an inner concave negative pole, A, of pure silver so mounted that its inverted image is thrown upon the opposite end of the tube. In front of this pole is a screen of mica, C, having a small hole in the centre, so that only a narrow pencil of rays from the silver pole can pass through, forming a bright spot, D, at the far end of the bulb. The exhaustion is about the same as in the previous tube, and the current has been allowed to pass continuously for many hours so as to drive off a certain portion of the silver electrode, and upon examination it is found that the silver has all been deposited in the immediate neighbourhood of the pole, whilst the spot, D, at the far end of the tube that has been continuously glowing with phosphorescent light is practically free from silver.

The experiment is too lengthy for me to repeat it here, so I shall not attempt it, but I have on the table the results for examination.

The identity of action of silver and aluminium in the first case, and the non-projection of silver in this second instance, in themselves are sufficient to condemn Dr. Puluj's hypothesis, since they prove that phosphorescence is independent of the material of the negative electrode. In front of me is a set of tubes that to my mind puts the matter wholly beyond doubt. The tubes contain no inside electrodes with the residual gaseous molecules, and with them I will proceed to give some of the most striking radiant matter experiments without any inner metallic poles at all.

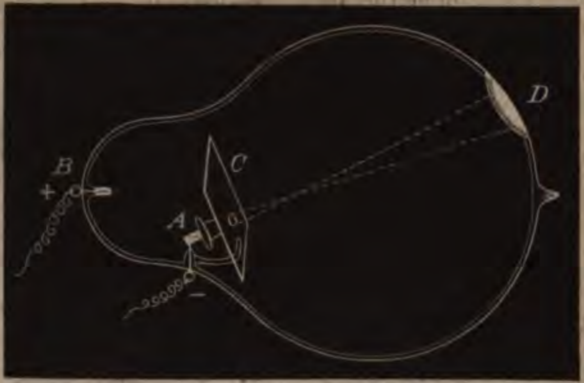

FIG. 16.—P. = 0·00068 mm. = 0·9 M.

In all these tubes the electrodes, which are of silver, are on the outside, the current acting through the body of the glass. The first tube contains gas only slightly rarefied and at the stratification stage. It is simply a closed glass cylinder, with a coat of silver deposited outside at each end, and exhausted to a pressure of 2 mm. The outline of the tube is shown in Fig. 17. I pass a current, and, as you see, the stratifications, though faint, are perfectly formed.

The next tube, seen in outline in Fig. 18, shows the dark space. Like the first, it is a closed cylinder of glass, with a central indentation forming a kind of hanging pocket, and almost dividing the tube into two compartments. This pocket, silvered on the air side, forms a

---

"The electrically excited negative pole supplies the *force majeure* which entirely, or partially, changes into a rectilinear action the irregular vibration in all directions."—*Proc. Roy. Soc.*, 1880, p. 472.

"It is also probable that the absolute velocity of the molecules is increased so as to make the mean velocity with which they leave the negative pole greater than that of ordinary gaseous molecules."—(*Phil. Trans.*, part ii., 1881, par. 719.)

* "It has been suggested that the extent of the dark space represents the mean free path of the molecules. . . It has been pointed out by others that the extent of the dark space is really considerably greater than the mean free path of the molecules, calculated according to the ordinary way. My measurements make it nearly 20 times as great. This, however, is not in itself a fatal objection; for, as we have seen, the mean free path of an ion may be different from that of a molecule moving among others."—Schuster, *Proc. Roy. Soc.*, xlvii., pp. 556-7.

† "Physical Memoirs," part ii., vol. i., p. 244. The paragraph is italicised in the original.

‡ *Loc cit.*, p. 242.

§ In a valuable paper read before the Royal Society, Nov. 20, 1890, by Profs. Liveing and Dewar, on finely-divided metallic dust thrown off the surface of various electrodes in vacuum tubes, they find not only that dust, however fine, suspended in a gas will not act like gaseous matter in becoming luminous with its characteristic spectrum in an electric discharge, but that it is driven with extraordinary rapidity out of the course of the discharge.

hollow glass diaphragm that can be connected electrically from the outside, forming the negative pole, A; the two ends of the tube, also outwardly silvered, form the positive poles, B B. I pass the current, and you all see the dark space distinctly visible. The pressure here is 0·076 mm., or 100 M.

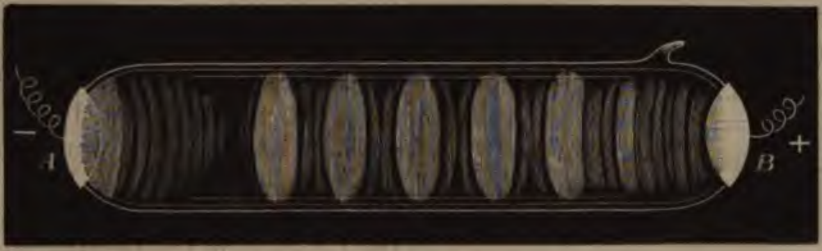

Fig. 17.—P. = 2·0 mm.

The next stage, dealing with more rarefied matter, is that of phosphorescence. Here is an egg-shaped bulb, shown in Fig. 19, containing some pure yttria, and a few rough rubies. The positive electrode, B, is on the bottom of the tube under the phosphorescent material, the negative, A, is on the upper part of the tube. See how well the rubies and yttria phosphoresce under molecular bombardment, at an internal pressure of 0·00068 mm., or 0·9 M.

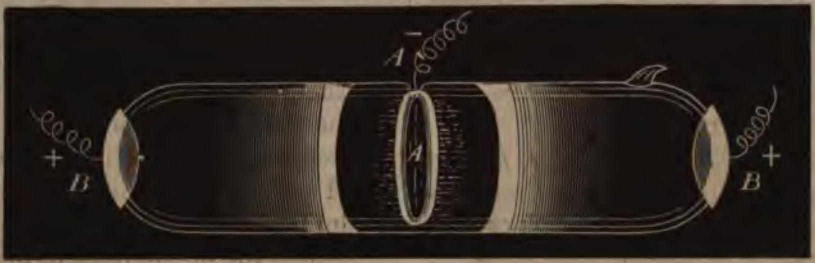

Fig. 18.—P. = 0·076 mm = 100·0 M.

A shadow of an object inside a bulb can also be projected on to the opposite wall of the bulb by means of an outside pole. A mica cross is supported in the middle of the bulb, Fig. 20, and on connecting a small silvered patch, A, on one side of the bulb with the negative pole of the induction coil, and putting the positive pole to another patch of silver, B, at the top, the opposite side of the bulb glows with a phosphorescent light, on which the black shadow of the cross seems sharply cut out. Here the internal pressure is 0·00068 mm., or 0·9 M.

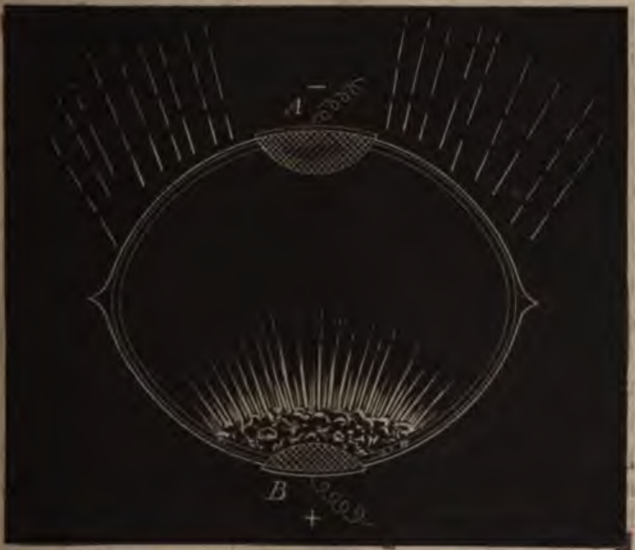

Fig. 19.—P. = 0·00068 mm. = 0·9 M.

Passing to the next phenomenon, I proceed to show the production of mechanical energy in a tube without internal poles. It is shown in Fig. 21* (P. = 0·001 mm., or 1·3 M.). It contains a light wheel of aluminium, carrying vanes of transparent mica, the poles, A B, being in such a position outside that the molecular focus falls upon the vanes on one side only. The bulb is placed in the lantern, and the image is projected on the screen; if I now pass the current you see the wheel rotates rapidly, reversing in direction as I reverse the current.

Here is an apparatus, Fig. 22*, which shows that the residual gaseous molecules when brought to a focus produce heat. It consists of a glass tube with a bulb blown at one end and a small bundle of carbon wool, C, fixed in the centre, and exhausted to pressure of 0·00076 mm., or 0·1 M. The negative electrode, A, is formed by coating part of the outside of the bulb with silver, and it is in such a position that the focus of rays falls upon the carbon wool.

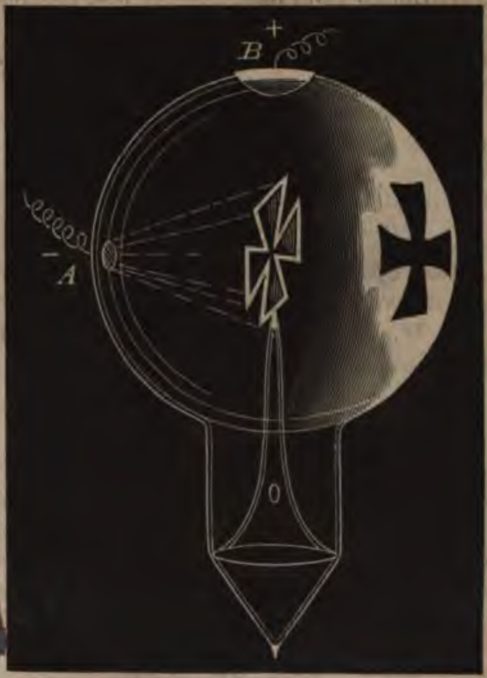

Fig. 20.—P. = 0·00068 mm. = 0·9 M.

The positive electrode, B, is an outer coating at the other end of the tube. I pass the current, and those who are close may see the bright sparks of carbon raised to incandescence by the impact of the molecular stream.

Vols. I. to VI. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

We may occasionally follow the lead of our American Contemporaries, especially when they point out a serviceable way. They are not backward in asking their friends to do all they can for the welfare of the paper. We ask our friends to remember us. No Paper that we know ever refuses Subscribers or Advertisers. Nor do we; in fact, we invite them, believing that they will get full value for their money.

Specimen copies of the paper will be sent on request.

1891.

In the ordinary course we should have completed our review of the past year and the forecast for the present in this issue, but we believe our readers will prefer to have the presidential address of Mr. Crookes complete rather than in instalments, so we have ventured to curtail other information for this purpose. It might be interesting to discuss the address, but really so few people have any real knowledge of the matter treated by Mr. Crookes that any criticism made thereon would serve only to show the ignorance of the critic. When other investigators have gone over the same ground as that explored by the President of the Institution, they will be able to give an opinion as to the validity of his conclusions. Meanwhile, it is better to admire his work than to criticise, and there is no doubt but that every scientific man will admire it, and credit the author with all the honour due to such a keen and brilliant investigator. Electrical engineers can appreciate the grappling with the unknown upon the boundaries of scientific knowledge even while they themselves feel the trammels of having to harness grosser matter for the purposes of their work.

Resuming our narrative, attention may be further called to the progress of transmission of power. It is admitted that here in England we hardly seem to appreciate the possibilities of distribution of power. No one can be said to be enthusiastic in its favour. Two or three tramways, one real railway, a few collieries, very little more, and all is told. In America, on the other hand, the circumstances are different, and there are in operation nearly three hundred street railways using electricity. Our hopes lie rather in the distribution of power from central stations than in the application of electricity to colliery and tramway work. The latter must come, and nothing as at present known can possibly stop it. The general introduction may be delayed, but it cannot be stopped; it may be gradual, but it will be effectual, in the long run displacing horseflesh. The very misfortune that attended the running at Birmingham ought to prove one of the strongest levers to rouse public opinion to the great cruelty to animals the use of horses on tramways perpetuates. It will be recollected that the contraction of the paving material caused a far greater pull to be required that was contemplated. The *Engineer* very pertinently remarked the horses could not speak of that unthought-of strain. The margin of safety in extra power was insufficient when electricity was employed, and had to be increased, or rather the rails have to be relaid without such possibility of contraction. We go into hysterics over some politician who has to sleep upon a plank bed, but the sentimentalists who are ready to weep and wail for something that happens in any other country are not found commiserating the cruelties practised under their noses. Two things will work for removing horse traction—the cost of buying horses will increase, as will the cost of forage. A slight rise in forage will bring electric traction to the front. As regards the South London Railway, it has been opened too recently to enable decided opinions to be given, but there is little doubt it will prove eminently successful. The demands of tramways, collieries, and railways ought to be small compared with the demand of power from central stations in every district except purely residential, and even in such districts the demand ought to be large. Is it that motors are too expensive to buy, or is it that the advantages of such apparatus are unknown to consumers? Mr. Crompton, as a rule, is pretty wideawake, and looks ahead. What is his experience at Kensington? Is there any demand for power, and has the constituency been approached on the subject? It may be taken for granted that tramway and colliery engineers know their business, and are not unaware of the claims of electricity, but the major part of the population which might use power are not in the same position of obtaining information. They do not read technical papers, and on this subject the ordinary reporter is silent. Supply companies and central station managers should consider this side of the question, and try to interest users of light to also use power.

The importance of power distribution is becoming more and more evident to those who have central installations. Arrange their plant how they will, for lighting only the cost of production per Board of Trade unit is increased at least a hundredfold, because of the inefficiency of the apparatus at low loads. In order that the production should be at the lowest possible cost, the machinery must be always working practically with a full load, and this is impossible unless the light distribution is supplemented by power distribution. The load diagram of any station will show that full load is carried only about one or two hours out of the 24. We may take it that with efficient engines and dynamos, with economical boilers and good stoking, a Board of Trade unit may be generated with the combustion of from 4·5lb. to 5lb. of coal, while we doubt if any central station can show a coal bill less than 10lb. of coal per unit generated. Thus there is just about 100 per cent. to work upon, and every addition to the load towards having full load constant is so much gain. This point is one worthy of the closest attention of those who pin their faith upon alternate-current systems and lighting only. They may find a millstone round their necks unless that much to be desired commercial alternate-current motor is forthcoming.

Appleton, Burbey, and Williamson.—During the year 1890 Messrs. Appleton, Burbey, and Williamson have been very busy manufacturing their electrical supplies for the trade, and their specialities have met with great success. Their business has so largely increased that in September they found it necessary to move their works to larger premises, and have taken a very commodious and convenient factory—viz., the Tower Bridge Electrical Works, Bermondsey. They have put down new plant and machinery, and are devoting special attention to improving the details in all electric lighting accessories. They have been especially busy with their patent switches and switchboards, the increase in this branch of their business being very marked. Recently they have commenced manufacturing electric bells, indicators, and signalling apparatus, and with special machinery for this work hope to do a large business. A new and complete price list has just been issued, and Messrs. Appleton, Burbey, and Williamson have spared no trouble to make this a useful and standard list for electrical engineers and contractors. They have considerable orders on hand, and are expecting a very busy year in 1891.

Manchester Edison-Swan Company.—This company have experienced a considerable increase in their business during 1890, 33,469 incandescent lamps having been supplied by them for the Lancashire district. In the commencement of the year they found it necessary to take additional premises in Little John-street, Manchester, on account of the increase in the manufacturing branch of their business. This, however, now proves to be inadequate, and it has been decided to move their works further out of the city, where a well-appointed and commodious factory will be built. In the installation department a large quantity of work has been carried out during the past year. Several important installations are at present in progress, among which may be mentioned 1,500 lights for the Wholesale Co-operative Society at Leicester; the lighting of the premises of the Derby Co-operative Society; the restaurant of Thos. Parker and Sons, Manchester; S. Hazzopulo's café, Brown-street, Manchester; the warehouse of Messrs. Frandenburg and Co., Greengate, Salford; the offices of the Manchester Ship Canal Company; the premises of J. Nelson, Esq., Bury; extension of the Bolton Co-operative Society installation; and the mansions of Lord Howard, of Glossop; Jos. Cliff, Esq., Brigg; J. C. Waterhouse, Esq., Prestbury; Mr. Wood, Glossop; and Jos. Wood, Esq., Chorley.

James Pitkin.—This firm are the exclusive makers of Capt. Holden's electric chronographs. These instruments, described in our issue of July 11th, 1890, are now being received with great favour, and are rapidly superseding all the older forms. They are exclusively used at the Woolwich Arsenal for measuring the velocity of projectiles as fired from large ordnance. They are also in use at the following establishments—viz., the Shoeburyness Small Arms Factory, Enfield; the Gatling Arms and Ammunition Co.; Messrs. Kynock and Co., Birmingham; Noebel's Explosives Co., Stephenson, N.B. Orders are now in hand for the Indian Government, and many other Government establishments both at home and abroad. An improved form of secondary battery is used to work the chronographs. This battery is the joint patent of Captain Holden and Mr. Pitkin. The Pitkin electric hand safety lamps are now in use at the Wigan Coal and Iron Company's collieries, the Ocean Colliery, South Wales, Cannock Chase Colliery, and several other mining companies; also at the Royal Gunpowder Factory, Waltham Abbey, Roslin Gunpowder Factory, near Edinburgh. Most of the large shipping companies use these lamps. They have also supplied a long-felt want on petroleum ships. As a safety lamp in gas works they are found to be of great service. Various forms of electrical measuring instruments have been designed and made. Among them is a very effective reflecting galvanometer of the D'Arsonval type, a simple ampere-meter, and a variable resistance. A new form of recording voltmeter is in course of construction; also a very compact little dynamo, which can be used either as a current generator or as a motor. Another of Mr. Pitkin's manufactures is Capt. Holden's open range hydrometer. This form of hydrometer is being received with much favour by users of storage batteries. Pitkin and Niblett's explosive gas detectors are found to be of much service in gas works, coal mines, ship holds, sewers, etc., or anywhere where explosive gases are liable to accumulate. Just recently a recording instrument of this type has been made. An electrically worked arrangement for communicating at a distant station the existence of dangerous accumulations of explosive gases at any given spot has been made; also an electric apparatus for giving an aural or visual alarm is in course of construction. Some other electric novelties now being introduced by this firm are an improved primary battery hand lamp, and a new magneto-electric bell and transmitter.

ADDRESS OF MR. WILLIAM CROOKES TO THE INSTITUTION OF ELECTRICAL ENGINEERS.

(Continued from page 63.)

You have thus seen that all the old "radiant matter" effects can be produced in tubes containing no metallic electrodes to volatilise. It may be suggested that the sides of the tube in contact with the outside poles become electrodes in this case, and that particles of the glass itself may be torn off and projected across and so produce the effects. This is a strong argument, which fortunately can be tested by experiment. In the case of this tube, Fig. 23 (P. = 0·00068 mm., or 0·9 M.), the bulb is made of lead glass phosphorescing blue under molecular bombardment. Inside the bulb, completely covering the part that would form the negative pole, A, I have painted a substantial coat of yttria so as to interpose a layer of this earth between the glass and the inside of the tube. The negative and positive poles are silver discs on the outside of the bulb, A being the negative and B the positive pole. If, therefore, particles are torn off and projected across the tube to cause phosphorescence, these particles will not be particles of glass, but yttria, and the spot of phosphorescent light, C, on the opposite side of the bulb will not be the dull blue of lead glass, but the golden yellow of yttria. You see there is no such indication; the glass phosphoresces with its usual blue glow, and there is no evidence that a single particle of yttria is striking it.

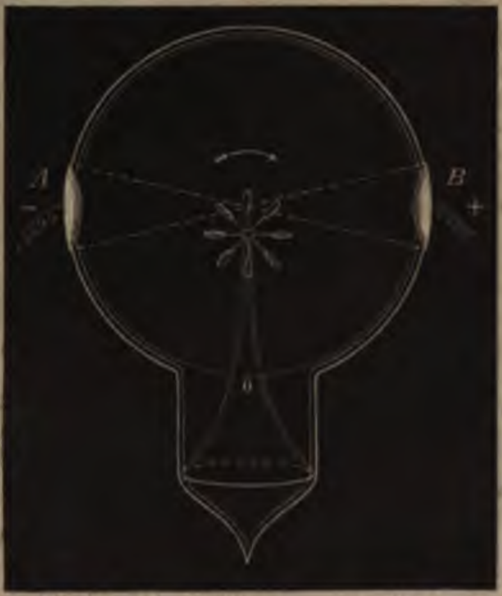

FIG. 21.—P. = 0·001 mm. = 1·3 M.

Witnessing these effects I think you will agree I am justified in adhering to my original theory that the phenomena a[illegible]d by the radiant matter of the residual gaseous molecules, and certainly not by the torn-off particles of the negative electrode.

PHOSPHORESCENCE IN HIGH VACUA.

I have already pointed out that the molecular motions rendered visible in a vacuum tube are not the motions of molecules under ordinary condition, but are compounded of these ordinary or kinetic motions, and the extra motion due to the electrical impetus.

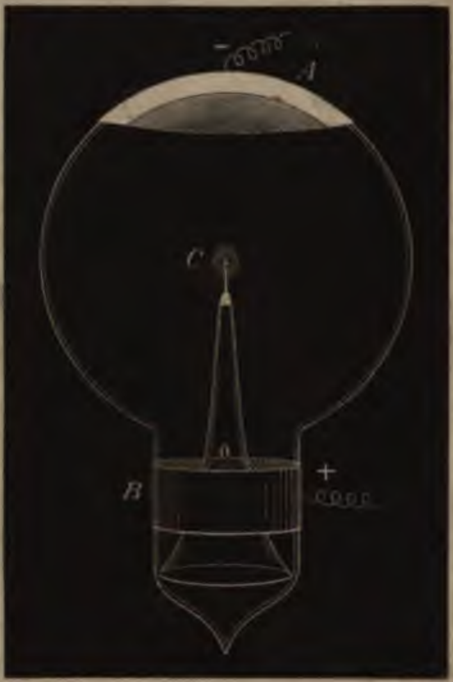

FIG. 22.—P. = 0·000076 mm. = 0·1 M.

Experiments show that in such tubes a few molecules may traverse more than a hundred times the *mean* free path, with a correspondingly increased velocity, until they are arrested by collisions. Indeed, the molecular free path may vary in one and the same tube, and at one and the same degree of exhaustion.

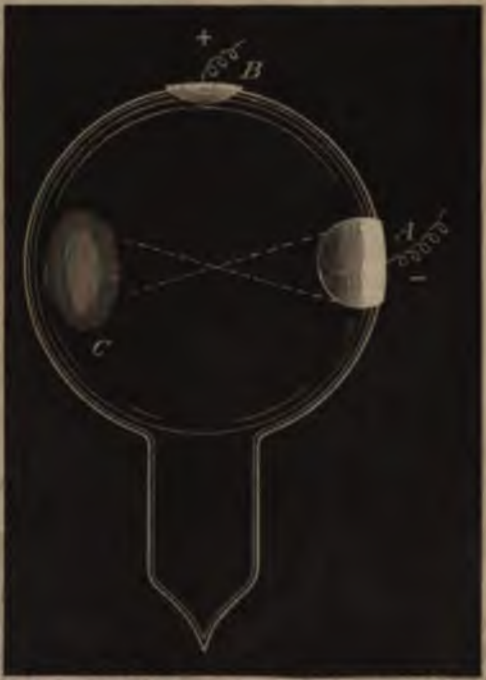

FIG. 23.—P. = 0·00068 mm. = 0·9 M.

Very many bodies, such as ruby, diamond, emerald, alumina, yttria, samaria, and a large class of earthy oxides and sulphides, phosphoresce in vacuum tubes when placed in the path of the stream of electrified molecules proceeding from the negative pole. The composition of the gaseous residue present does not affect phosphorescence; thus, the earth yttria phosphoresces well in the residual vacua of atmospheric air, of oxygen, nitrogen, carbonic anhydride, hydrogen, iodine, sulphur, and mercury.

With yttria in a vacuum tube, the point of maximum phosphorescence, as I have already pointed out, lies on the margin of the dark space. The diagram, Fig. 24, shows approximately the degree of phosphorescence in different parts of a tube at an internal pressure of 0·25 mm., or 330 M. On the top you see the positive and negative poles, A and B, the latter having the outline of the dark space shown by a dotted line, C. The curve, D E F, shows the relative intensities of the phosphorescence at different distances from the negative pole, and the position inside the dark space at which phosphorescence does not occur. The height of the curve represents the degree of phosphorescence. The most decisive effects of phosphorescence are reached by making the tube so large that the walls are outside the dark space, whilst the material submitted to experiment is placed just at the edge of the dark space.

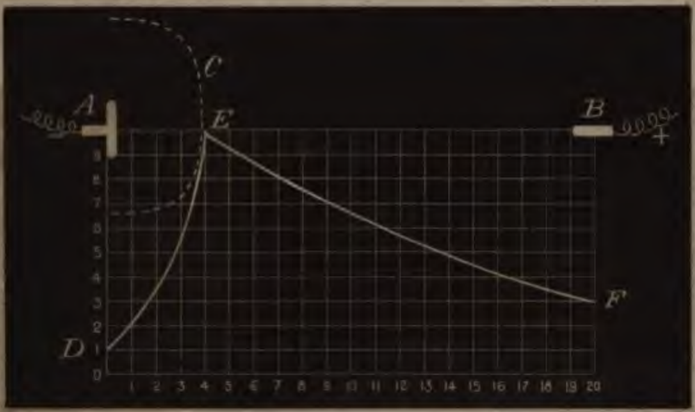

Fig. 24.—P. = 0·25 mm. = 330·0 M.

Hitherto I have spoken only of phosphorescence of substances placed under the negative pole. But from numerous experiments I find that bodies will phosphoresce in actual contact with the negative pole.

This is only a temporary phenomenon, and ceases entirely when the exhaustion is pushed to a very high point. The experiment is one scarcely possible to exhibit to an audience, so I must content myself with describing it. A U-tube, shown in Fig. 25, has a flat aluminium pole, in the form of a disc, at each end, both coated with a paint of phosphorescent yttria. As the rarefaction approaches about 0·5 mm. the surface of the negative pole, A, becomes faintly phosphorescent. On continuing the exhaustion this luminosity rapidly diminishes, not only in intensity, but in extent, contracting more and more from the edge of the disc, until ultimately it is visible only as a bright spot in the centre. This fact does not prop a recent theory, that as the exhaustion gets higher the discharge leaves the centre of the pole, and takes place only between the edge and the walls of the tube.

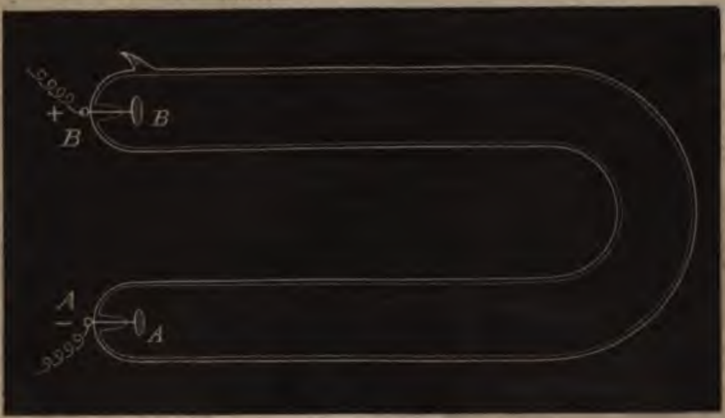

Fig. 25.

If the exhaustion is further pushed, then at the point where the surface of the negative pole ceases to be luminous, the material on the positive pole, B, commences to phosphoresce, increasing in intensity until the tube refuses to conduct, its greatest brilliancy being just short of this degree of exhaustion. The probable explanation is that the vagrant molecules I introduce in the next experiment, happening to come within the sphere of influence of the positive pole, rush violently to it and excite phosphorescence in the yttria, whilst losing their negative charge.

Loose and Erratic Molecules.

In the brief time left to me this evening I cannot touch upon the mass of experiments made to render this result clear, so I will at once show you a piece of apparatus that clearly illustrates the cause of phosphorescence at the positive pole. A drawing of this tube is shown at Fig. 26, but let me first explain the effect I expect to obtain, and then endeavour to show the actual experiment.

A C B is a U-shaped tube with terminals, A and B, at each end; D and E are two mica screens covered with a phosphorescent powder, having at F and G other screens with a small slit in front, so as to allow only a narrow beam of charged molecules to pass through. At first the tube is exhausted to a pressure of 0·076 mm. or 100 M., and you see how sharp and slightly divergent is the luminous image on screen D, whilst not a trace of phosphorescence is to be seen on the screen E in the other limb of the tube. Now I push the exhaustion to the highest point short of non-conduction (0·000076 mm., or 0·1 M.), and the phenomena change. The initial line of light on D becomes wider and unsteady, whilst at the gate, G, a decided phosphorescence is observable entering the second screen, E. This luminosity diverges to a considerable extent, much more than did the stream of charged molecules observed in the first limb of the tube at the lower exhaustion. This is only to be expected, inasmuch as those sparse molecules which have run the gauntlet of the crowd and have been hunted and buffetted round the corner will have little or no lateral support, but wander to the furthest part of the tube, and altogether behave differently to the orderly procession of molecules at more moderate exhaustion.

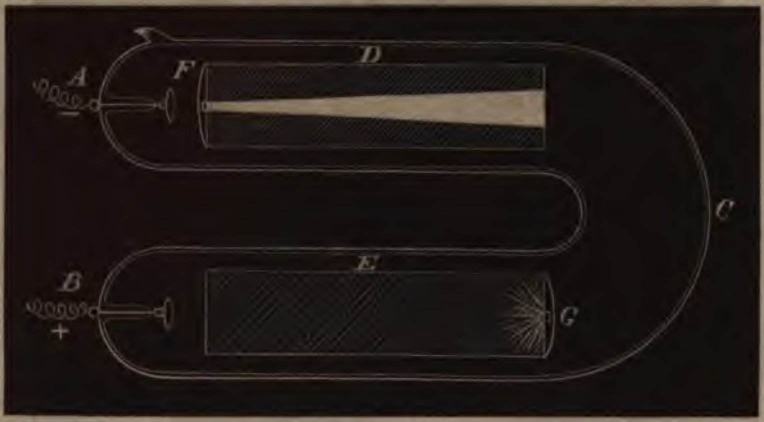
THE RESISTANCE OF HIGH VACUA.

I must only lightly touch this phenomenon to-night; it is a subject of deep interest, and one to which I have lately devoted much time. Shortly I hope to publish a full account of results recently obtained.

The passage of an induction current at a high vacuum through a tube depends much upon the material of the tube or the substance enclosed within it. Given the same degree of exhaustion, and the same distance between the terminals inside the tube, the E.M.F. necessary to force the current through may vary from 3,000 volts to 20,000 volts, according to the particular material used.

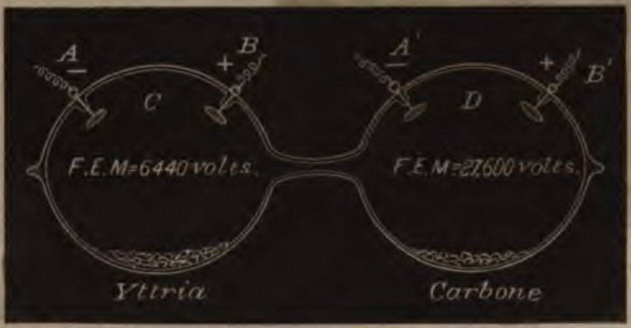
Here is a very striking example that will serve to illustrate this phenomenon. Fig. 27 is a double tube joined by a narrow open channel and therefore in the same state of exhaustion throughout (P. = 0·02 mm., or 26 M.). Each tube is furnished with a pair of poles, A B and A′ B′. One tube contains the phosphorescent earth yttria, the other contains finely-divided carbon. I first connect the yttria tube, C, to the coil, and place in parallel circuit with it a spark gauge. To begin with, this gauge is set to a gap of 1 mm. (An E.M.F. of 920 volts is necessary to strike across 1 mm. of air; therefore the difference of potential at the terminals inside the yttria tube is 920 volts, and this you perceive is not sufficient to force the current through the tube.) I now gradually open the gauge until the potential of the inner terminals has risen to a point high enough to allow the spark to pass through the tube, making the yttria phosphorescent.

FIG. 26.—P. = 0·076 mm. = 100·0 M.



P. = 0·000076 mm. = 0·1 M.

FIG. 27.—P. = 0·02 mm. = 26·0 M.



= 6440 = 27,600

The gap is at 7 mm. equal to an E.M.F. of 6,440 volts. I next attach the coil wires to the tube, D, containing the carbon, and the exhaustion in the tubes being the same as before, I repeat the experiment; you now see that the gap has to be opened to 30 mm., equivalent to an E.M.F. of 27,600 volts, before the current will pass through the tube. The fact of whether the vacuum tube contains yttria or carbon makes a difference of 21,160 volts in the E.M.F. required to cause a discharge between the terminals.

One other experiment I would like to show in further illustration of this resistance. The idea suggested itself that possibly differences in the material or conductivity of the particular bulbs might influence the results you have just seen. Here, Fig. 28, is a long cylindrical tube of phosphorescent Bohemian glass containing a pair of terminals, A B; it also contains a shorter cylinder of glass, C C, brightly silvered inside. The internal pressure is 0·00068 mm., or 0·9 M. The silver cylinder is now at one end of the tube out of the way of the terminals, which therefore have phosphorescent glass around them. I turn on the coil and find that the E.M.F. necessary to force the current through, now that the terminals are in a phosphorescent chamber, is 1,380 volts. I slide the cylinder down to the end of the tube so as to enclose the terminals in a metallic silver chamber, and you see the E.M.F. necessary to pass the current rises to 6,440 volts. Metallic silver does not phosphoresce, whilst Bohemian glass phosphoresces very well. It appears that the greater the phosphorescing power of the substance surrounding the poles so much the easier does the induction spark pass. Surround the poles with Bohemian glass or yttria—two phosphorescent non-conductors of electricity—and the induction spark passes easily; immediately I surround the terminals with a non-phosphorescent conductor the current refuses to pass.

WHAT OCCASIONS PHOSPHORESCENCE?

I should like to interest you in a question that has exercised my mind for some time past. What is it that occasions the phosphorescence of yttria and other bodies in vacuo under molecular bombardment?

So far I have found this phosphorescence to be an attribute of non-conductors only. We know that in the act of phosphorescence the molecules of yttria are in a state of intense vibration. Each molecule may be viewed as the radiating centre of the entire bundle of rays, which, when decomposed by the prism, displays a discontinuous spectrum. We may also suppose that the residual atoms of gas charged with negative electricity give off their electricity on coming in collision with a phosphorescent body, and on their return take up a fresh charge.

THE ELECTROLYSIS HYPOTHESIS.

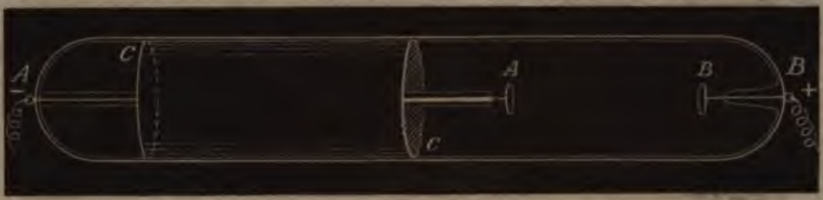
There is a certain amount of evidence in favour of an electrolytic hypothesis of the passage of electricity through rarefied gases. This has been ably advocated by Prof. Schuster in the Bakerian lecture before the Royal Society, March 20th, 1890.*

A molecule of hydrogen gas, for instance, may be made up of one group of atoms of hydrogen having an equivalent of negative electricity inherent in it, and one group of atoms having an equivalent of positive electricity bound up with it. These atoms are also charged with *additional* equivalents of positive or negative electricity, which they carry about as a ship carries its cargo. We are not concerned with the inherent electricity—of which we are ignorant—but with the extra or "cargo" charge. Let us imagine a molecule of hydrogen near the face of the negative pole in a vacuum tube. I turn on the current, and the atoms of the hydrogen molecule are dragged apart. The positive atom is attracted to the negative pole, where the violence of impact, or the discharge of electricity, renders it apparent with evolution of light. The internal luminous layer, which is closely adjacent to the negative electrode, is due, therefore, to the positive atoms rushing to the negative pole, and not, like the glow round the edge of the dark space, to the negative atoms projected from it. The negative atom, on the other hand, is driven violently from the negative pole, in virtue of the mutual repulsion existing between any two bodies similarly electrified, with a velocity varying with the intensity of the electrification, and the degree of the vacuum; the more perfect the vacuum the greater the velocity, the atoms flying outwards in straight lines until they meet with an obstacle. Such an obstacle may be a procession of positively charged atoms from the positive pole. In this case the two kinds of atoms mutually discharge each other's cargoes with a display of light. This phenomenon occurs at the margin of the dark space when the vacuum is only moderate; or the obstacle may be produced by the vacuum being so high that the atoms of gas present are too few to form a continuous procession. (*Why* a high vacuum should be non-conductive does not clearly appear, but the fact itself is beyond doubt. It is probably connected with the inability of electrified atoms to leave the poles.) Or, again, the obstacle may be a phosphorescent body like yttria. In this case the negatively-charged atoms deliver up their charge of electricity to the yttria, which is so constituted—perhaps, after the manner of a Hertz resonator—that its atoms charge and discharge, vibrating about 550 billion times in a second, and producing waves in the ether of the length, approximately, of 5·74 ten millionths of a millimetre, and occasioning in the eye the effect of citron light.

---

* Royal Society's *Proc.*, xlvii., 526.

Fig. 28.—P. = 0·00068 mm. =0·9 M.



Silver Cylinder off Poles E.M.F. = 1380 Volts.

Silver Cylinder round Poles E.M.F. = 6440 Volts.

We are not under the necessity of supposing that this number of hydrogen atoms are driven against the yttria in the second, although even at a high vacuum there are quite enough atoms left in the bulb to keep up such a supply. All that is needed is that a succession of shocks, not necessarily rhythmical, may strike the yttria at frequencies which will set up such a number of vibrations, just as a series of slow impacts on a gong causes it to emit sound waves of much greater frequency.

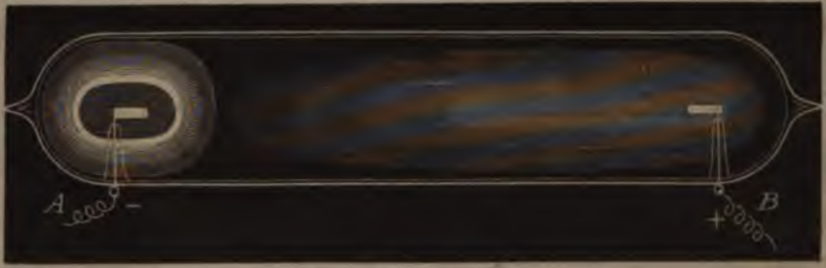


Fig. 29.

In a low vacuum only very few atoms can run the gauntlet among the crowd of inrushing atoms, and those few which succeed in reaching the yttria arrive with much reduced velocity, and so faint is the phosphorescence they set up that it is completely obscured* by the brighter phosphorescence of the residual gas. As the vacuum becomes higher, more and more atoms find their way across, and their speed being at the same time accelerated, the phosphorescence becomes intensified.

At a good vacuum most of the atoms hit the yttria, their velocity is increased, and the rhythmical excitation reaches its maximum.

THE DARK SPACE IN MERCURY VAPOUR.

In applying the electrolytic hypothesis, I have used for illustration's sake the gaseous residue of hydrogen, which is known as a diatomic gas. I have found, however, the phenomena of the dark space, etc., to occur in the vapour of mercury, which is a monatomic gas. This important result induced me to patiently investigate this subject, and the result of one experiment is before you, Fig. 29. The tube is furnished with aluminium terminals, and is so arranged that the induction spark can be kept passing during exhaustion to drive off occluded gases. When at the highest attainable vacuum, the tube is filled with pure mercury by simply raising a reservoir. On applying heat the entire contents of the tube are boiled away and pass down the fall tubes of the pump, exhaustion going on at the same time. When the whole of the mercury has thus been boiled away *in vacuo*, except a little condensed at the upper part of the tube, the results on passing the spark are as follows: when the tube is cold the induction current refuses to pass; on gently heating with a gas-burner the current passes and the dark space is distinctly visible. Continuing the heat so as to volatilise the drops of mercury condensed on the sides, the whole tube becomes filled with a green phosphorescent light, the dark space gets smaller and smaller, and ultimately the negative pole becomes covered with a luminous glow. On allowing the tube to cool the same phenomena ensue in inverse order. The luminous halo expands, showing the dark space between it and the pole, and this dark space gradually grows larger as the tube becomes cooler. The mercury again condenses on the side of the tube, the green phosphorescence grows paler and paler, until at last the induction spark from the large coil refuses to pass.

At first sight this result appears fatal to the electrolytic hypothesis, for if the molecule of mercury contains only one atom how can we talk of its separation into positive and negative atoms by the electric stress? It must be remembered, however, that we are as yet ignorant of the absolute mass of the atom of any element. All that can be said is that a molecule of free hydrogen becomes halved in combining chemically with certain other elements, whilst a molecule of free mercury does not suffer division on yielding any known compound of mercury; the physical atoms in the one behave as two separate groups, and those in the other as one undivided group. It has been agreed by chemists, for simplicity's sake, and for facilitating chemical calculations, to reduce the units to the lowest term consistent with the avoidance of fractions; we therefore say that the atoms in a molecule of free hydrogen act in chemistry as two separate groups, each of a minimum relative weight of 1, whilst those in a molecule of free mercury act as one undivided group of the relative weight 200. But to what number of atoms the 1 and 200 correspond respectively no chemist knows.

---

* This faint phosphorescence at a low vacuum can be rendered visible by the electrical phosphorscope described in my lecture at the Royal Institution in 1887.

To show how intimately chemistry and electricity interlock, I may here remark that one of the latest theories in chemistry renders such a division of the molecule into groups of electro-positive and electro-negative atoms necessary for a consistent explanation of the genesis of the elements. This is so important, that I may be excused for digressing a little into this development of theoretical chemistry.

GENESIS OF THE ELEMENTS.

It is now generally acknowledged that there are several ranks in the elemental hierarchy, and that, besides the well-defined groups of chemical elements, there are underlying sub-groups. To these sub-groups has been given the name of meta-elements. The original genesis of atoms assumes the action of two forms of energy working in time and space —one operating uniformly in accordance with a continuous fall of temperature, and the other having periodic cycles of ebb and swell, and intimately connected with the energy of electricity, Fig. 30. The centre of this creative force in its journey through space scattered seeds or sub-atoms that ultimately coalesced into the groupings known as chemical elements. The law which governs the motions of multitudes of men and women in a busy thoroughfare, I have applied to the atoms of gas in a vacuum tube. At this genetic stage the new-born particles vibrating in all directions and with all velocities, the faster moving ones would still overtake the laggards, the slower would obstruct the quicker, and we should have groups formed in different parts of space. The constituents of each group whose form of energy governing atomic weight was not in accord with the mean rate of the bulk of the components of that group would work to the outside, and be thrown off to find other groups with which they were more in harmony. In time a condition of stability would be established, and we should have our present series of chemical elements, each with a definite atomic weight—definite on account of its being the average weight of an enormous number of sub-atoms or meta-elements, each very near to the mean. The atomic weight of mercury, for instance, is called 200, but the atom of mercury, as we know it, is assumed to be made up of an enormous amount of sub-atoms, each of which may vary slightly round the mean number of 200 as a centre.

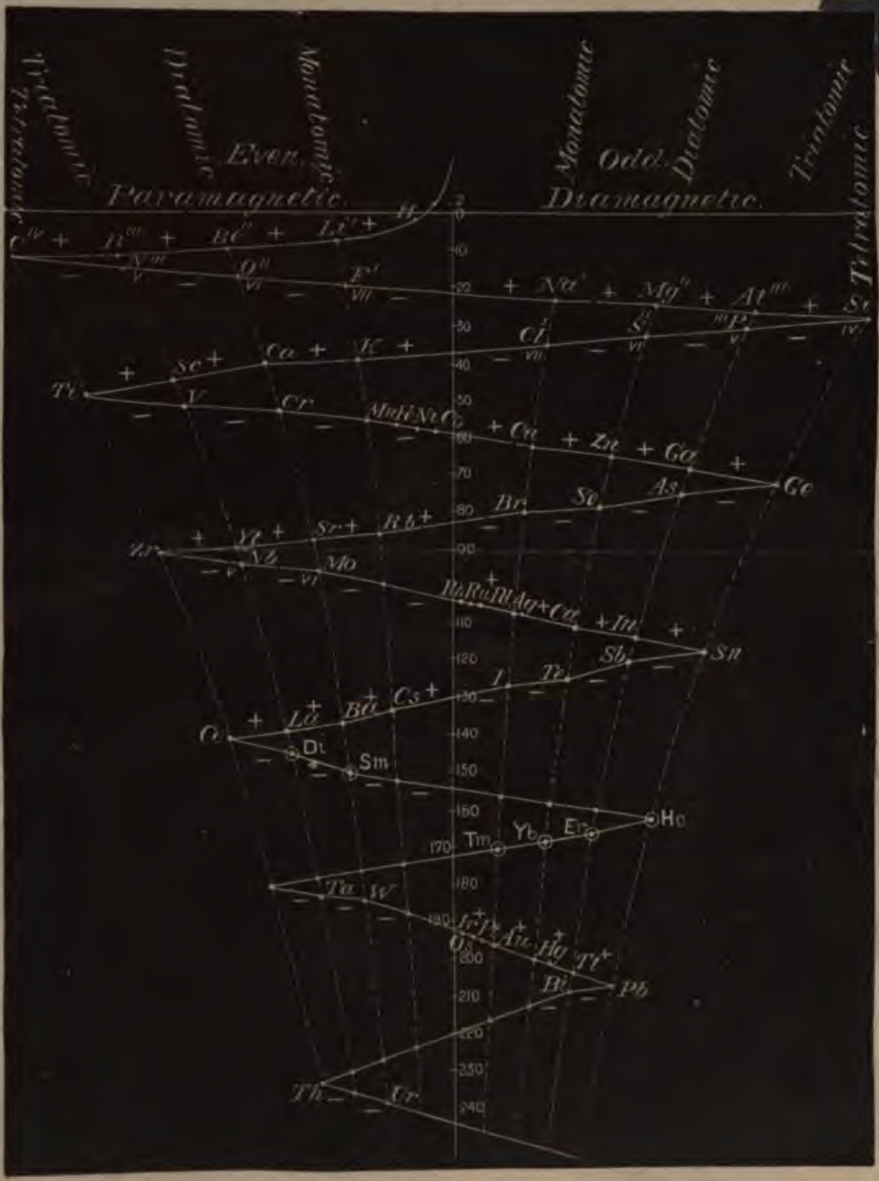

FIG. 30.

We are sometimes asked why, if the elements have been evolved, we never see one of them transformed, or in process of transformation, into another? The question is as futile as the cavil that in the organic world we never see a horse metamorphosed into a cow. Before copper, *e.g.*, can be transmuted into gold, it would have to be carried back to a simpler and more primitive state of matter, and then, so to speak, shunted on to the track which leads to gold.

This atomic scheme postulates a to-and-fro motion of a form of energy governing the electrical state of the atom. It is found that those elements generated as they approach the central position are electro-positive, and those on the retreat from this position are electro-negative. Moreover, the degree of positiveness or negativeness depends on the distance of the element from the central line, hence, calling the atom in the mean position electrically neutral, those sub-atoms which are on one side of the mean will be charged with positive electricity, and those on the other side of the mean position will be charged with negative electricity, the whole atom being neutral.

This is not a mere hypothesis, but may take the rank of a theory. It has been experimentally verified as far as possible with so baffling an enigma. Long-continued research in the laboratory has shown that in matter which has responded to every test of an element, there are minute shades of difference which have admitted of selection and resolution into meta-elements, having exactly the properties required by theory. The earth yttria, which has been of such value in these electrical researches as a test of negatively excited atoms, is of no less interest in chemistry, having been the first body in which the existence of this sub-group of meta-elements was demonstrated.

CONCLUSION.

I frankly admit I have by no means exhausted the subject which daily and nightly fills my thoughts. I have ardently sought for facts on which to base my theory. I have struggled with problems which must be conquered before we can arrive at exact conclusions—conclusions which, so far as inorganic Nature is concerned, can only be reached by the harmonious interfusion—not confusion—of our present twin sciences, electricity and chemistry. Of this interfusion I have just endeavoured to give you a foretaste. In elaborating the higher physics, the study of electrical phenomena must take a large, perhaps the largest, share.

We have invaded regions once unknown, but a formidable amount of hard work remains to be completed. As we proceed we may look to electricity not only to aid, as it already does, our sense of hearing, but to sharpen and develop other powers of perception.

Science has emerged from its childish days. It has shed many delusions and impostures. It has discarded magic, alchemy, and astrology. And certain pseudo-applications of electricity, with which the present Institution is little concerned, in their turn will pass into oblivion.

There is no occasion to be disheartened at the apparent slow pace of elemental discovery. The desponding declare that if Roger Bacon could revisit "the glimpses of the moon" he would shake his head to think we have got no further, that we are still in a haze as to the evolution of atoms. As for myself, I hold the firm conviction that unflagging research will be rewarded by an insight into natural mysteries such as now can scarcely be conceived. Difficulties, said a keen old statesman, are things to be overcome, and to my thinking science should disdain the notion of finality. There is no stopping half way, and we are resistlessly driven to ceaseless enquiry by the spirit "that impels all thinking things, all objects of all thought, and rolls through all things."

CORRESPONDENCE.

COST OF PRODUCING ELECTRICAL ENERGY.

To THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—Mr. W. P. J. Fawcus, in your issue of the 12th ult., criticises some statements I made in the preceding number of your valuable journal, and I beg indulgence at this late date to again refer to the matters in question. Mr. Fawcus calls into question my remark that the cost of producing electrical energy *averages* 3¾d. per unit in the majority of central stations, and brings figures to prove that this is quite absurd, his figures being obtained from mill installations and others of similar kind. Now, I should like to ask your correspondent if he really considers the two cases parallel instances, remembering the vital point that current must never be off in the case of central station work, and that—take what system you will, A C, with continuous engine power, or B T with the 30 to 40 per cent. loss in the secondary cells—the cost of production, leaving the important one of distribution out of account, the charge on the station per unit will not be much heavier in the case of public supply than in the other one of private installation. Of course if you include distribution, you make a worse case out against the central station. In mentioning such figures as those referred to, I had in mind certain stations to whose data I have access, and on whose results the owners have much reason to congratulate themselves. Surely the basis for comparison, *gas* with electricity, is a good one of 5 cubic feet = 16 c.p., when in this town 4 cubic feet = 16 c.p., and in many cases of large gas consumers an efficiency of five to 10 candles per cubic foot is obtained by use of the regenerative lamps now so common. It must also be remembered that an incandescent can do no more than displace one gas jet, and even then the *effect* in an office or shop in winter is not so good as that formerly obtained with gas. In the case of a small central station I was connected with it was found more economical to use lamps of full candle-power, when, as I stated in my letter, 600 hours was the average life, and I find that consumers reckon in London and here one year as the life of a lamp. How many hours does Mr. Fawcus take this to be?—Yours, etc., CHARLES H. YEAMAN.

Electric Department, Liverpool Corporation,
January 13, 1891.

THE CITY AND SOUTH LONDON RAILWAY.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—I shall be obliged if you will kindly insert the enclosed copy of letter which I have addressed to the *Electrician*.—Yours, etc., A. WILLBOND.

[COPY.]

THE CITY AND SOUTH LONDON RAILWAY.

To the Editor of the "ELECTRICIAN.'

Sir,—In the last issue of your journal you state: "During the first fourteen days ending on Saturday last the receipts amounted to £1,947, showing that 233,640 passengers had been carried during that period, or on an average 16,688 per day; that is to say, nearly 40 per cent. more than was estimated by the pessimistic Mr. A. Willbond." This is all very well in its way, and might have passed muster amongst your readers were it not for the extraordinary fact—which seems to have escaped your attention in making up—that you have yourself discounted your own figures by stating that it must "be borne in mind that novelty is only a temporary attraction, and that comfort and regularity will alone secure permanent patronage."

The figures given by me in the *Electrical Review* were based upon permanent traffic, and I have found when travelling on the railway that the actual number of passengers carried was, on several occasions, only a *very small* percentage higher than given in my estimate. "It is, moreover, to be borne in mind that novelty" which "is only a temporary attraction," was at that time still temporarily attracting.

I hope that your readers who have read the two leaderettes in question will find my letter at least a "temporary attraction."—Yours truly,

London, Jan. 13, 1891. A. WILLBOND.

P.S.—When about to post this letter, I find that the official return for last week's traffic give the total receipts as £748. Thus, notwithstanding "temporary attraction," the average number of passengers carried per day was only 12,823, or about 7¼ per cent. more than the number given in my estimate.

UNDERGROUND MAINS.—II.

THE CROMPTON SYSTEM.

(Continued from page 9.)

When the culverts are finished, the next process is the actual drawing in of the mains. These come in copper strip 1in. wide by ⅛in. thick, just as rolled from the mill. They are uncoiled and stamped out straight on the ground by the workmen's feet, and the length between the straining-boxes is measured and cut off. In the first place a cord is passed through the culvert, and usually for this an ingenious and simple method is adopted. At the Kensington station may be seen a curly-haired black dog, a permanent official of the works. This dog, with a cord attached to his collar, is put into the culvert and the top closed in. The men then go to the next box and call the dog, who creeps along, drawing the cord, and so on to the end. The cord is then attached to a chain, and the chain in its turn to the copper strip, which is then drawn in by the men.

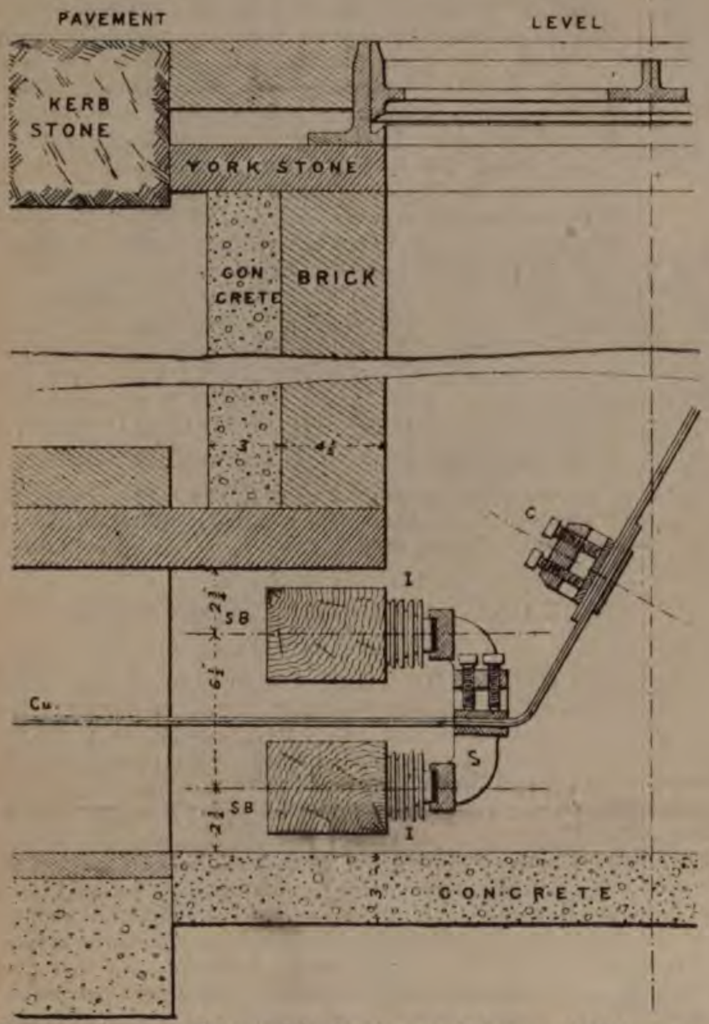

FIG. 8.—Joint from Culvert under Roadway to Culvert under Pavement.

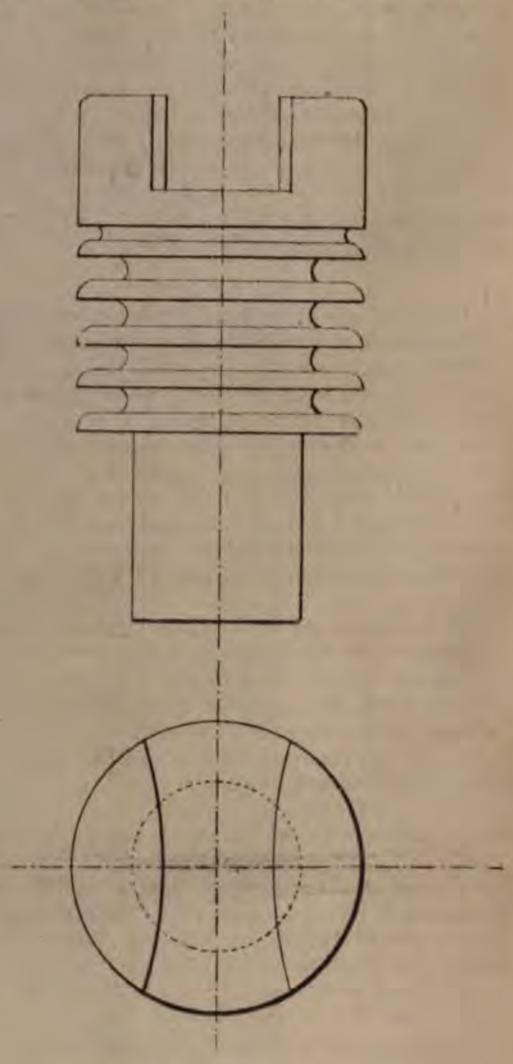

FIG. 11.—Crompton Insulator.

At each insulator box the glass insulators are now pressed into the holes (1¼in. diameter) in the timber baulk. These insulators, I, are of the form shown in the illustration, with five deep rings to give a long length of insulating surface, and thus to guard against leakage by moisture creeping. The insulation is still further increased by each insulator being previously dipped in hot copal varnish. The head of each insulator is slotted out of a width to receive the copper strip. As each strip is drawn past, a man stands at each insulator box along the route and lifts the strip into its position upon the insulator. The three or more strips are thus successively drawn in.

FIG. 10.—Box Cover for Straining or Insulator Boxes.—Section.

The copper strips having been passed into the culvert are yet lying along the bottom. They have now to be stretched sufficiently taut to be everywhere in air, except where they touch at the insulating supports. A sag of about 2½in. in the mains is usually allowed between the insulators.

The straining pieces, S, each consist of a bridge or arch made of gunmetal, of the shape shown in the illustrations, and carefully designed to afford the requisite stability, both for resistance to the strain of the copper mains, and for holding these latter absolutely fixed, while at the same time obtaining the highest possible insulation. The insulation is assured by the use of glass insulators with deep grooves, similar to those already mentioned, but more solid and squat to withstand the strain.

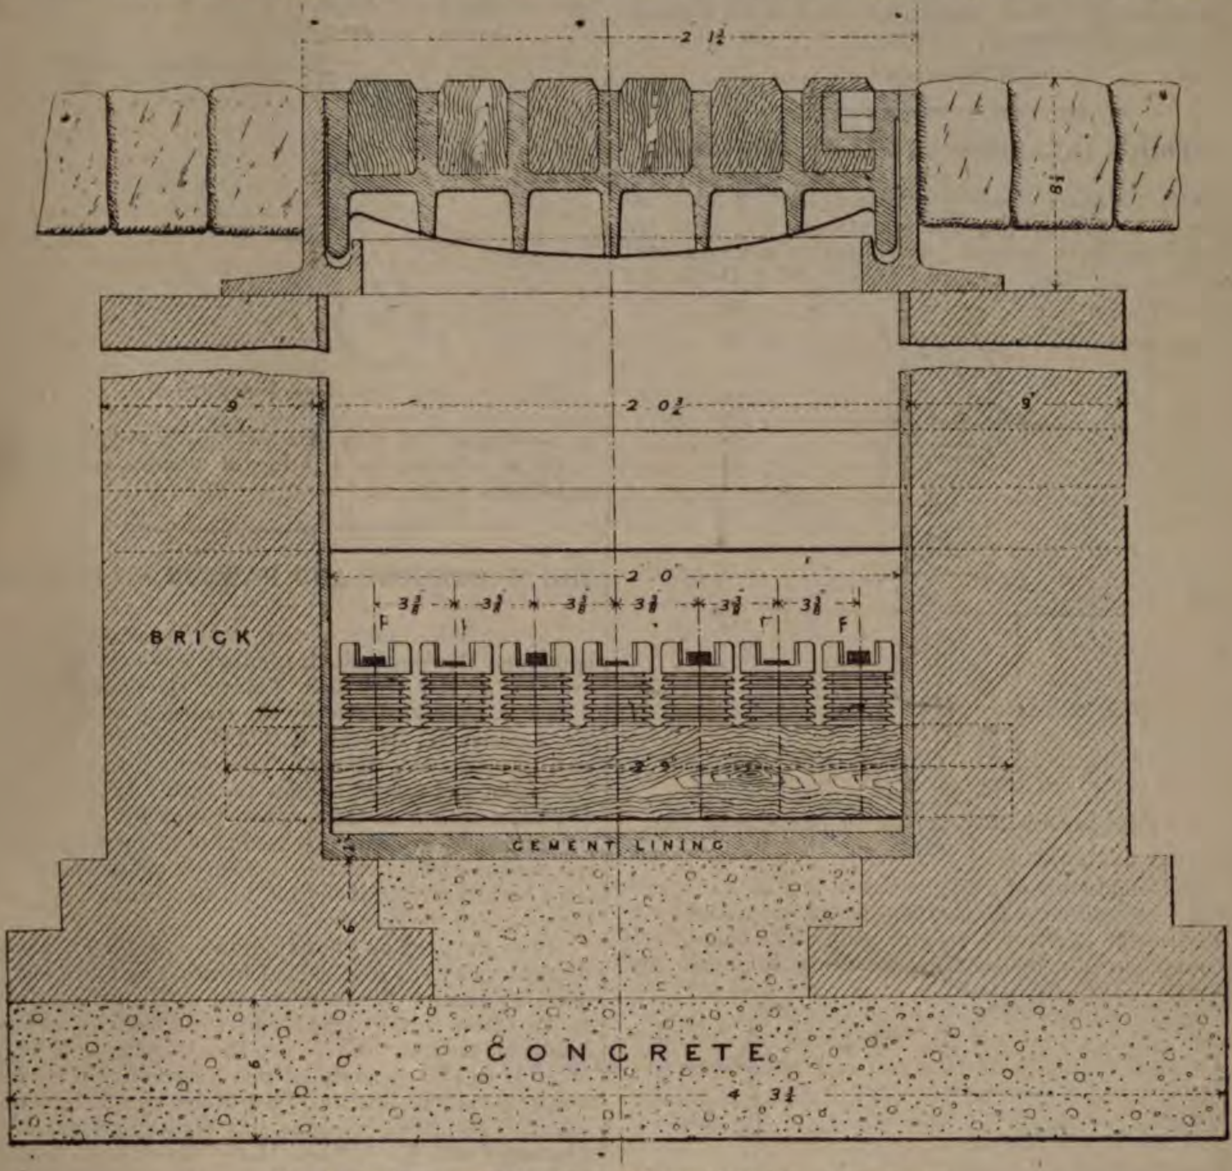

FIG. 9.—Culvert under Roadway with Wood Blocks.—Cross-section.

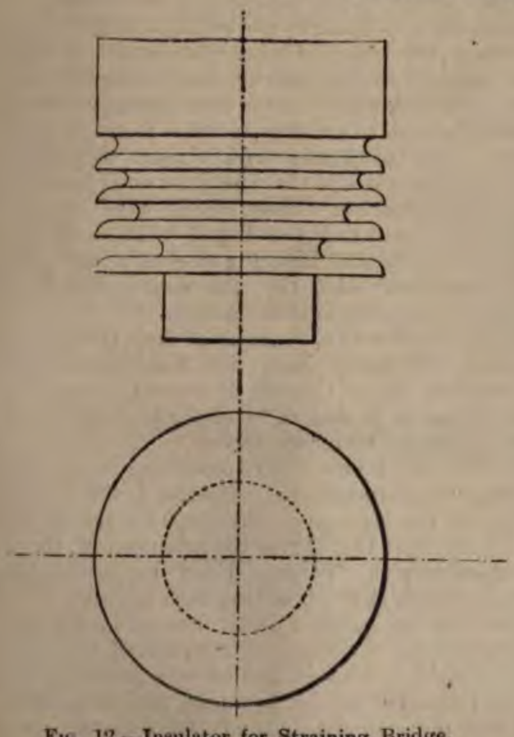

FIG. 12.—Insulator for Straining Bridge.

In placing them into position, a ring or pad of solid indiarubber, R, is first placed against the straining baulk upon these are placed the glass insulators, I I, and then a second pad of solid indiarubber is placed over each insulator, which are thus evenly bedded and enabled to withstand the heavy end strain without the edges chipping off. The gunmetal bridge straining pieces, S, are then placed in position, and the copper main, Cu, is passed through the slot in the centre. It should be noticed that this slot is made with the lower side sloped, or wedge-shaped. A loose piece inside the slot screws down tightly upon the copper main, which is thus slightly bent, and becomes firmly fixed or wedged in position, so that by this simple means the more the strain on the main the tighter it is gripped. The pinching screws are made of aluminium bronze or Delta metal, or in dry situations of steel.

The straining is accomplished in various ways. The most scientific and certain is that often used of a hydraulic jack, made to form a lever to draw the mains up tight. Placed in position at the side of the trench, bedded against the concrete edge, a few strokes of the hydraulic handle tightens up the main, and the pinching screws are then screwed tightly down upon the wedge-piece, W. The straining for shorter lengths is also often done by the simple means of ropes and pulleys, or by a crowbar strained against a baulk, or sometimes by a right or left-handed screw. The means employed are mainly dependent upon the length of the strip, and thus upon the necessity for greater or less force.

When the copper strips are properly tightened from straining-box to straining-box, the ends are overlapped and tightly connected together by a grip box or connecting-box, C, which simply presses the ends of the flat strips firmly together by means of pinching screws. These grip-boxes are large enough to hold four strips, but can be made to hold six strips if necessary.

(*To be continued.*)

OUTDOOR INCANDESCENT LAMP FITTINGS.

High candle-power incandescent lamps are now taking so prominent a position that special fittings for them are becoming largely in demand. We illustrate herewith some types of these fittings made by Messrs. John Davis and Son, Derby.

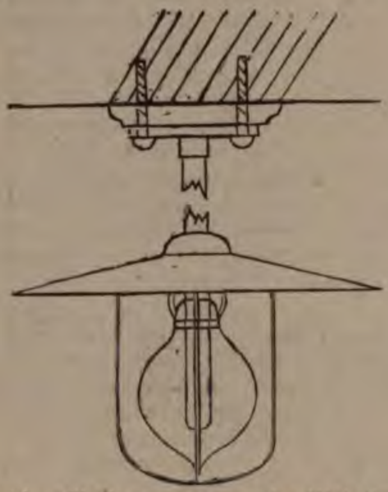

Fig. 1.—Outdoor Shade and Reflector for High Candle-power Lamps.

A very usual style of fitting is shown in Fig. 1. It consists of a wrought-iron bracket and flange, or wrought-iron straight stalk, to fix to a roof or wall. The lamp is contained in a glass shade, with a strong iron case and reflector.

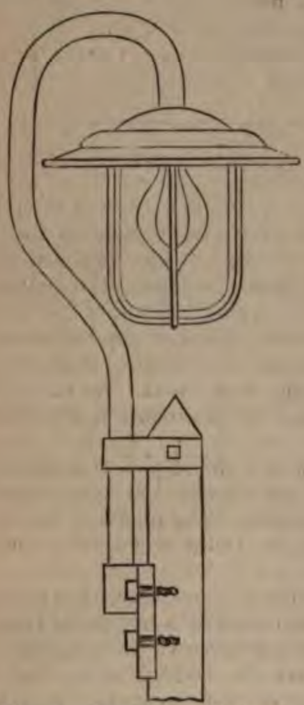

Fig. 2.—Shadowless Fitting.

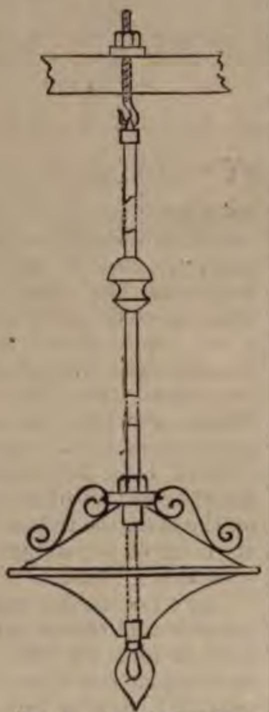

Fig. 4.—Arcade Pendant.

The so-called "shadowless" fitting shown in Fig. 2 is constructed on similar lines, and is designed to fix on the top of a pole, so that the light casts no shadow in any direction. Both of these are found very useful for lighting large spaces.

Another useful form is shown in Fig. 3, consisting of a wrought-iron bracket or straight stalk with a double conical enamelled iron reflector. This pattern is designed for indoor work, where the lamp does not require protection.

Fig. 4 is a fitting of very similar description more elaborately finished. It has a double enamelled reflector and is ornamented with four gilt scrolls and two gilt balls, and is suitable for the lighting of arcades, entrance halls, and similar positions.

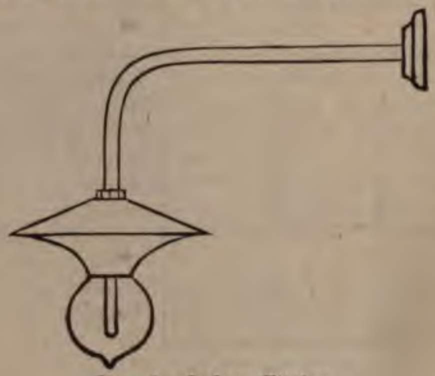

Fig. 3.—Indoor Fitting.

THE WOODHOUSE AND RAWSON STAFF DINNER.

The annual dinner of the head office staff of Woodhouse and Rawson United, Limited, was held on Tuesday evening, at the Guildhall Tavern, Gresham-street. The dinner was presided over by the chairman of the company, Sir Rawson W. Rawson, K.C.M.G., C.B., and there were also present Sir Edward Thornton, Captain Rawson, Dr. Maier, and others, besides the staff. It was extremely successful both from the numbers (some 100 or 120 attending with most evident good feeling of fellowship), also from the announcements of the company's praiseworthy intentions with regard to their staff for the coming year given in the course of the speeches.

When the good and hearty dinner had been disposed of, finished up by the seasonable Christmas pudding, the president, Sir Rawson W. Rawson, paid a very touching tribute to the Queen in the course of his loyal toast by relating the events of kindred Rawsons in the Ashantee and Egyptian War. It will be remembered that a naval officer guided the forces across the desert at Tel-el-Kebir by the light of the stars. This officer, it seems, was Wyatt Rawson, one time lieutenant with his brother, Harry Rawson, on board Her Majesty's private yacht. He led the forces accurately to the spot, joined in the attack and was fatally wounded, dying on his way home to his young wife. The Queen, on decorating the other brother on return of the forces, spoke feelingly to him, making the poor fellow break down utterly and rush away; asked him specially to dinner, and expressed a wish to stand godmother to the orphaned baby girl just born, conjointly with himself as godfather, and with the express desire that the little one's name should be Victoria Alexandrina. These deeds were related both as touchingly illustrating the Royal toast, and as bodying forth the true English honour and enterprise in many fields of the Rawsons, who, the chairman pointed out, were strongly represented in this meeting.

Mr. H. Masterman, manager of their Kidsgrove Works, proposed "The Army, Navy, and Auxiliary Forces," which was responded to by Captain Rawson ("as good an electrician as he is a soldier," said the proposer) and by Mr. Mumford for the merchant service.

Sir Rawson Rawson, in responding to the toast of the evening, "Woodhouse and Rawson United, Limited, the Board, and the Managing Director," on behalf of himself and his son, said that it was the intention of the company to supplement the Pension Fund by establishing some system of profit sharing, so that each member of the company should feel he has a direct interest in the welfare and the profit of the company. The credit of the intention, he said, belonged to his son, and he only claimed for himself and his colleagues on the board an entire approval of the aims and objects, and trusted the scheme would make Woodhouse and Rawson United show an example of a really united body—strong, healthy, and prosperous.

Mr. F. L. Rawson, in responding to the same toast, gave first some very good advice to the young men on the staff upon the subject of good work and promotion. The company now employ, he said, very nearly 1,000 men on their various branches, and indirectly as many more. The chances for men of good habits and ability were therefore considerable. He gave some of the qualities most desirable, ranking reliability above simple ability, pointing out that for managers of a large enterprise to be absolutely sure that what a man undertakes that will he always and certainly do is better than knowing a man to be able to do more and yet not be certain of his doing it. Civility was another great thing to be desired amongst themselves as well as to outsiders, and the man who is easy to get on with is more likely to be himself aided, so likewise the man who is not afraid of giving nothing for nothing—work done apparently for nothing being often paid for again and again—and an amusing picture was drawn of his own younger days when, as a lad, he undertook to design a house for a lady, designs which were not paid for, though many a £10 note has since come from this lady's influence. Before all he would impress them to give good work and good work only; they had not only to think about their present position, but about their position in two or three years time; many of them would be getting married, and even now there seemed quite an epidemic of marriages setting in, of which he was afraid he himself offered a bad example. After this "fatherly" advice he went on to speak of the position of the company. It had been objected that much of their work had been connected with new companies, but it must be recollected that outside people knew very little of the very large amount of actual work that they were also doing, though the staff of course did. They had been passing through a preparatory time in electrical matters, and no one else was making very much out of it, so that they ought to be glad even in this preparatory time the company was paying well. With regard to the Pension Fund full particulars would be given before very long. He was glad to announce that a library for the staff had been started at 34, Cannon-street, and would be well supplied with technical books and newspapers, and arrangements had also been made for a number of lectures to the staff in the evenings. With regard to their already-established system of quarterly bonuses, it had been the habit of the company to offer premiums of two guineas and a guinea for the best invention submitted. This had been originally confined to the works department; they had, however, determined to throw it open to all and to increase it by a five guinea bonus for the best invention, improvement, or suggestion for the business. A committee would be formed to award the premiums once a quarter, and so encourage a constant interest in the firm's work and progress. To better carry out this interest and intercourse between all the branches, it was intended to issue a newspaper, either by themselves, or by arrangement in conjunction with some other journal. With regard to profit-sharing, he did not believe in any scheme of charity, or in helping people, unless in a thorough way, one beneficial to the business as well as to themselves. They hoped to do it in such a way that other firms would also take up the idea, arranging a well-digested scheme so that part of the increase of business should go the employés and part to the firm, and so helping forward the millennium, or whatever else they were going to have in the future.

Mr. L. BROEKMAN, in giving "The General Manager," gave Mr. North great credit for organising ability, both at home and in their foreign extensions, and spoke of the good relations between the manager and the various departments.

Mr. G. NORTH, in responding, gave some fuller particulars of the proposed lectures to the staff. He always advocated a sound mind in a sound body, and in physical ability the company's men in lacrosse, cricket, and football excelled, he thought, all electrical firms. He would like them equally to excel in regard to soundness of minds. When he was asked for situations open (and he was often besieged by numbers of men—young, middle-aged, and sometimes quite old) too often this was the kind of conversation that occurred when he put them through a short examination. He would ask them if they knew shorthand. Well, they *had* learnt it, couldn't write much, but could soon pick it up, no doubt. Languages? They had learnt French at school, didn't remember much of it. Bookkeeping? They didn't know, but thought they could do it—if they were shown the way! Electricity? Yes, they knew something about that; they had used a plate machine at school!' Engineering, mechanics? No, they knew nothing about that. Now, he would ask what on earth were the use of such men as these? The world was full of them. The men the company wanted were those that *could* do something and *did* know something. To help the present staff to better themselves in useful knowledge the company had made arrangements to have a series of lectures, not too technical, upon electrical subjects. The lectures will be free, and will be given at 34, Cannon-street, at half-past six, beginning on Friday, January 16th. The introductory lecture will be given by Mr. Stepney Rawson and the chairman of the company. Sir Rawson Rawson will take the chair on this occasion to give additional *éclat*. It will be illustrated by specimens, diagrams, and a certain number of experiments. The succeeding lectures will be as follows: Mr. Epstein (manager of accumulator department) on secondary batteries; Mr. Nalder on measuring instruments; Mr. Bryan on dynamos and motors; Mr. Stepney Rawson on incandescent lamps; Mr. Thomas (contract department) on arc lamps; Mr. Stuart A. Russell (I.R.G.P.Co.) on testing; Mr. Marsh (supply department) on telephones; and Mr. Reg. J. Jones (contract manager) on installation work. These will be followed by several others on engines, on boilers, and on electric launches. A shorthand class is being conducted by Mr. Harland, also free of charge, and the company intend to make a special condition of engagement on their staff, that everyone shall be able or must learn to write 80 or 100 words a minute.

Mr. W. STEPNEY RAWSON briefly proposed "The Branches," and Mr. H. S. KING, in responding, said it might be truly said that the sun never sets on the Woodhouse and Rawson branches, as they were now established in all parts of Her Majesty's kingdom. It must be remembered that besides their numerous supply branches abroad and in the colonies, they had a very extensive engineering branch in the North, and were now in the proud position of being, he believed, the only electrical company or firm who could carry out an entire installation to light a town without any outside help. Woodhouse and Rawson stood, he said, something like the Westinghouse Company in America, and could supply the whole material for a town, theatre, or private house installation—boilers, engines, dynamos, insulators, wires, everything from their own branches.

Mr. REGINALD J. JONES briefly proposed "The Visitors," coupling with it the name of Dr. Julius Maier, who responded by wishing all the prosperity to the company which they richly deserved

Sir EDWARD THORNTON gallantly proposed an additional toast of "The Ladies," which, amidst much enthusiasm, was responded to by Miss Rawson, who, with Mrs. F. L. Rawson and Miss Fife, had helped in the musical part of the proceedings.

To the toast of "The Chairman," given by Mr. T. D. Dundas, Sir RAWSON RAWSON notified his pleasure in being able to attend at such a full and congenial gathering of the firm's employés, and added, as an incentive to further and willing work, that his own progress in life had been due to his hard and willing work as a simple clerk in the Board of Trade Office having attracted the notice of the Vice-President, so that now after a career of 47 years in the public service he was now, as he hoped they would be in their time, able to enjoy old age in the kindness of friends and associates.

With musical honours a most enjoyable and interesting evening was then brought to a close.

Matlock Bath.—The Local Board have appointed a committee to consider the question of introducing electric lighting into the town. Mr. Geo. Fletcher, electrical engineer to the Midland Railway Company, and Mr. Cameron, of Exeter, have been consulted on the subject. The former estimates the cost of lighting the streets, using water power, at £1,064, and with private lighting added, £2,100.

THE ELECTROMAGNET.*

BY PROF. SILVANUS P. THOMPSON, D.SC., B.A., M.I.E.E

LECTURE IV.

(*Continued from page 48.*)

Again, a suggestion has been made to enclose in an iron jacket the coil employed in this way. Iron-clad solenoids have been employed from time to time. But they do not increase the range of action. What they do is to tend to prevent the falling off of the internal pull at the region within the mouth of the coil. It equalises the internal pull at the expense of all external action. An iron-clad solenoid has practically no attraction at all on anything outside of it, not even on an iron core placed at a distance of half a diameter of the aperture; it is only when the core is inside the tube that the attraction begins, and the magnetising power is practically uniform from end to end. Last year I wished to make use of this property for some experiments on the action of magnetism on light, and for that purpose I had built, by Messrs. Paterson and Cooper, this powerful coil, which is provided with a tubular iron jacket outside, and a thick iron disc perforated by a central hole covering each end. The magnetic circuit around the exterior of the coil is practically completed with soft iron. With this coil, one may take it, there is an absolutely uniform magnetic field from one end of the tube to the other; not falling off the ends, as it would do if the magnetic circuit had simply an air return. The whole of the ampere-turns of exciting power are employed in magnetising the central space, in which therefore the actions are very powerful and uniform. The coil and its uses were described in my lecture last year at the Royal Institution on "Optical Torque."

MODIFICATIONS OF THE COIL AND PLUNGER.

In one variety of the coil and plunger mechanism, a second coil is wound on the plunger. Hjorth used this modification, and the same thing has been employed in several arc lamps. There is a series of drawings upon this wall depicting the mechanism of about a dozen different forms of arc lamp, all made by Messrs. Paterson and Cooper. In one of these there is a plunger with a coil on it drawn into a tubular coil, the current flowing successively through both coils. In another there are two separate coils in separate circuits, one of thin wire and one of thick, one being connected in series with the arc, and one in shunt.

DIFFERENTIAL COIL AND PLUNGER.

There is a third drawing here showing the arrangement, which was originally introduced by Siemens, wherein a plunger is drawn at one end into the coil that is in the main circuit, and at the other end into a coil that is in shunt. That differential arrangement has certain peculiar properties of which I must not now stop to speak in detail. It is obvious that where one core plunges its opposite ends into two coils, the magnetisation will depend on both coils, and the resultant pull will not be simply the difference between the pull of the two coils acting separately. There is, however, another differential arrangement, used in the Brockie-Pell and other arc lamps, in which there are two separate plungers attached to the ends of a see-saw lever. In this case the two magnetising actions are separate. In a third differential arrangement there is but one plunger and one tubular bobbin, upon which are wound the two coils, differentially, so that the action on the plunger is simply due to the difference between the ampere-turns circulating in the two separate wires.

COIL AND PLUNGER COIL

When one abandons iron altogether, and merely uses two tubular coils, one of wide diameter, and another of narrower diameter capable of entering into the former, and passes electric currents through both of them, if the currents are circulating in the same fashion through both of them they will be drawing into one another. This arrangement has also been used in arc lamps. The parallel currents attract one another inversely, not as the square of the distance, but approximately as the distance. This is one of those little details about which it is as well to be clear. About once a year some kind friend from a distance writes to me pointing out a little slip that occurs in my book on electricity, in the passage where I am speaking about the attraction of parallel wires. I have made the terrible blunder of leaving out the word "square"; for I say the attraction varies inversely as the distance, and my readers are kind enough to correct me. Now, when I wrote that passage I considered carefully what I had to write, and the attraction does not vary inversely as the square of the distance, because two parallel wires do not act on one another as two points. They act as two straight lines or two parallel lines, and the attraction between two parallel lines of current, or two parallel lines of magnetism, or two parallel lines of anything else that can attract, will not act inversely as the square, but simply inversely as the distance in between.

INTERMEDIATE FORMS.

Now this property of the coil and plunger of extending the range of action has been adopted in various ways by inventors whose object was to try and make electromagnets with a sort of intermediate range. For certain purposes it is desirable to construct an electromagnet which, while having the powerful pull of the electromagnet, should have over its limited range of action a more equable pull, resembling in this respect the equalising of range of the coil and plunger. Some of these intermediate forms of apparatus are shown in the following diagrams. Here, Fig. 65, is a peculiar form of electromagnet: it combines some of the features of the iron-clad electromagnet with those of the movable plunger; it has a limited range of action, but is of great power over that range, owing to its excellent magnetic circuit. It was invented, in 1870, by Stevens and Hardy, for use in an electric motor for running sewing machines. A very similar form is used in Weston's arc lamp. A form of plunger electromagnet invented by Holroyd Smith in 1877 resembles Fig. 65 inverted; the coil being surrounded by an iron jacket, whilst a plunger, furnished at the top with an iron disc, descends down the central tube to meet the iron at the bottom.

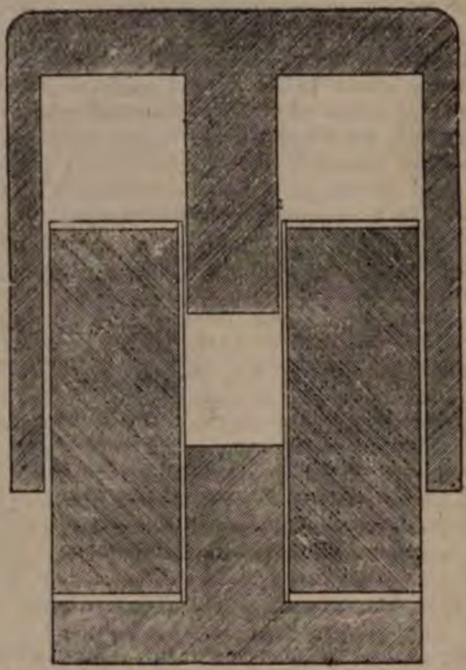

FIG. 65.—Plunger Electromagnet of Stevens and Hardy.

Then there is another variety, of which I was able to show an example last week by the kindness of the Brush Company—namely, the plunger electromagnet employed in the Brush arc lamps. A couple of tubular coils receive each an iron plunger, connected together by a yoke; whilst above, the magnetic circuit is partially completed by the sheet of iron which forms part of the enclosing box. You have here, also, the advantage of a fairly complete magnetic circuit, together with a comparatively long travel of the plunger and coil. It is a fair compromise between the two ways of working. The pull is not, however, in any of these forms equal all along the whole range of travel; it increases as the magnetic circuit becomes more complete.

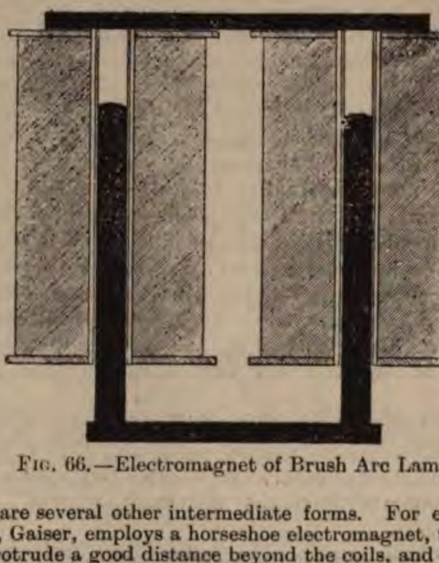

FIG. 66.—Electromagnet of Brush Arc Lamp.

There are several other intermediate forms. For example, one inventor, Gaiser, employs a horseshoe electromagnet, the cores of which protrude a good distance beyond the coils, and for an armature he employs a piece of sheet iron, bent round so as to make at its ends two tubes, which enclose the poles, and are drawn down over them. Contrast with this design one of much earlier date by an engineer, Roloff, who made his electromagnets with iron cores not standing out, but sunk below the level of the ends of the coils, whilst the armature was furnished with little extensions that passed down into these projecting tubular ends of the coils. Some arc lamps have magnets of precisely that form, with a short plunger entering a tubular coil, and met half-way down by a short fixed core inside the tube.

Here, Fig. 67, is one form of tubular iron-clad electromagnet that deserves a little more attention, being the one used by Messrs. Ayrton and Perry in 1882; a coil has an iron jacket round it, and also an annular iron disc across the top, and an annular iron disc across the bottom, there being also a short internal tube of iron extending a little way down from the top, almost meeting another short internal tube of iron coming up from the bottom. The magnetic effect of the enclosed copper coil is concentrated within an extremely short space, between the ends of the internal tubes, where there is a wonderfully strong uniform field. The range of action you can alter just as you please in the construction by shortening or lengthening the internal tubes. An iron rod inserted below is drawn with great power and equality of pull over the range from one end to the other of these internal tubes.

---

* Cantor lectures, delivered before the Society of Arts.

ACTION OF MAGNETIC FIELD ON SMALL IRON SPHERE.

In dealing with the action of tubular coils upon iron cores, I showed how, when a very short core is placed in a uniform magnetic field, it is not drawn in either direction. The most extreme case is where a small sphere of soft iron is employed. Such a sphere, if placed in even the most powerful magnetic field, does not tend to move in any direction if the field is truly uniform. If the field is not uniform, then the iron sphere always tends to move from the place where the field is weak to a place where the field is stronger. A ball of bismuth or one of copper tends, on the contrary, to move from a place where the field is weaker. This is the explanation of the actions called "diamagnetic," which were at one time erroneously attributed to a supposed diamagnetic polarity opposite in kind to the ordinary magnetic polarity. A simple way of stating the facts is to say that a small sphere of iron tends to move up the slope of a magnetic field with a force proportional to that slope; whilst (in air) a sphere of bismuth or one of copper tends, with a feeble force, to move down that slope. Any small piece of soft iron—a short cylinder, for example—shows the same kind of behaviour as a small sphere. In some of Ayrton and Perry's coiled-ribbon ampere-meters and voltmeters, and in some of Sir William Thomson's current-meters, this principle is applied.

SECTIONED COILS WITH PLUNGER.

An important suggestion was made by Page, about 1850, when he designed a form of coil and plunger having a travel of indefinitely long range. The coiled tube, instead of consisting merely of one coil, excited simultaneously throughout its whole length by the current, was constructed in a number of separate sections or short tubes, associated together end to end, and furnished with means for turning on the electric current into any of the sections separately. Suppose an iron core to be just entering into any section, the current is turned on in that section, and as the end of the core passes through it the current is then turned on in the section next ahead. In this way an attraction may be kept up along a tube of indefinite length. Page constructed an electric motor on this plan, which was later revived by Du Moncel, and again by Marcel Deprez in his electric "hammer."

WINDING OF TUBULAR COILS AND ELECTROMAGNETS.

The mention of this mode of winding in section leads me to say a few final words about winding in general. All ordinary coils, whether tubular or provided with fixed cores, are wound in layers of alternate right-handed and left-handed spirals. In a preceding lecture I mentioned the mistaken notion, now disproved, that there is any gain in making all the spirals right-handed or all left-handed. For one particular case there is an advantage in winding a coil in sections, that is to say, in placing partitions or *cloisons* at intervals along the bobbin, and winding the wire so as to fill up each of the successive spaces between the partitions before passing on from one space to the next. The case in which this construction is advantageous is the unusual case of coils that are to be used with currents supplied at very high potentials, for when currents are supplied at very high potentials there is a very great tension* exerted on the insulating material, tending to pierce it with a spark. By winding a coil in *cloisons*, however, there is never so great a difference of potentials between the windings on two adjacent layers as there would be if the layers were wound from end to end of the whole length of coil. Consequently, there is never so great a tension on the insulating material between the layers, and a coil so wound is less likely to be injured by the occurrence of a spark.

Another variety of winding has been suggested—namely, to employ in the coils a wire of graduated thickness. It has been shown by Sir William Thomson to be advantageous in the construction of the coils of galvanometers to use for the inner coils of small diameter a thin wire; then, as the diameter of the windings increase, a thicker wire; the thickest wire being used on the outermost layers; the gauge being thus proportioned to the diameter of the windings. But it by no means follows that the plan of using graded wire, which is satisfactory for galvanometer coils, is necessarily good for electromagnets. In designing electromagnets it is necessary to consider the means of getting rid of heat; and it is obvious that the outer layers are those which are in the most favourable position for getting rid of this heat. Experience shows that the under layers of coils of electromagnets always attain a higher temperature than those at the surface. If, therefore, the inner layers were to be wound with finer wire, offering higher resistance, and generating more heat than the outer layers, this tendency to overheating would be still more accentuated. Indeed, it would seem wise rather to reverse the galvanometer plan, and wind electromagnets with wires that are stouter on the inner layers and finer on the outer layers.

Yet another mode of winding is to employ several wires united in parallel, a separate wire being used for each layer, their anterior extremities being all soldered together at one end of the coil, and their posterior extremities being all soldered together at the other. Magnetically, this mode of winding presents not the slightest advantage over winding with a single stout wire of equivalent section. But it has lately been discovered that this mode of winding with multiple wire possesses one incidental advantage—namely, that its use diminishes the tendency to sparking which occurs at break of circuit.

EXTENSION OF RANGE BY OBLIQUE APPROACH.

I now pass to the means which have been suggested for extending the range of motion, or of modifying its amount at different parts of the range, so as to equalise the very unequable pull. There are several such devices, some electrical, others purely mechanical, others electro-mechanical. First, there is an electrical method. André proposed that as soon as the armature has begun to move nearer and comes to the place where it is attracted more strongly, it is automatically to make a contact, which will shunt off part of the current and make the magnetism less powerful. Burnett proposed another means, a number of separate electromagnets acting on one armature, but as the latter approached these electromagnets were one after the other cut out of the circuit. I need not say the advantages of that method are very hypothetical. Then there is another method which has been used many times with very great success—the method of allowing the motion of the armature to occur obliquely, it being mechanically constrained so as to move past instead of towards the pole. When the armature is pulled thus obliquely the pull will be distributed over a definite wider range. Here is a little motor made on that very plan. A number of pieces of iron set on the periphery of a wheel are successively attracted up sideways. An automatic device breaks the circuit as every piece of iron comes near, just at the moment when it gets over the poles, and the current being cut off, it flies on beyond and another piece comes up, it is also attracted in the same way, and then allowed to pass. A large number of toy motors have been made from time to time on this plan. I believe Wheatstone was the first to devise the method of oblique approach about the year 1841. He made many little electromagnetic motors, the armatures of which were in some cases solid rims of iron arranged as a sort of wheel, with two or more zig-zag internal teeth, offering oblique surfaces to the attraction of an electromagnet.

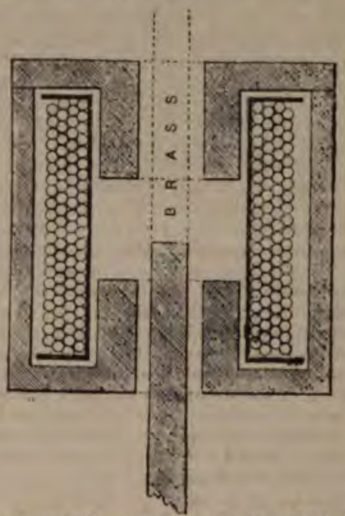

FIG. 67.—Ayrton and Perry's Tubular Iron-clad Electromagnet.

(*To be continued.*)

HOW ELECTRICITY WORKS FOR US.

On Saturday, January 10, a popular lecture was given in the schoolroom of Essex Church, The Mall, Notting Hill Gate, by Mr. Reginald J. Jones, A.M.I.C.E., M.I.E.E., engineer to Messrs. Woodhouse and Rawson United, Limited, on electricity, entitled "How Electricity works for us."

The subject was dealt with firstly as to its historical facts, such as early knowledge respecting the attractive and repulsive powers of amber when rubbed. This section was experimentally illustrated by a very fine plate influence machine of the Wimhurst type. To lead up to the second section, "Telegrams, and how they are sent," facts concerning magnetism were illustrated by some beautiful slides, showing the lines of magnetic force around magnets and wire, the mariner's compass, and construction of electromagnets, etc. Experiments were shown to demonstrate the immense pull or strength that could be got out of electromagnets. Following this some slides were shown illustrating Galvani's experiment with the frog's legs, Volta's pile, modern batteries, and then an experiment showing the deflection of a needle by means of a current, and by reversal of the same, the getting of signals suitable for telegraph work. Various instruments used in telegraphy for the different systems—such as Morse, single-needle, etc.—were exhibited in working order, and the telegraph codes were clearly shown by means of a slide giving the name of the church written in telegraph language. A most striking experiment, showing how thermometer fire-alarms act, was tried by means of a thermometer set to ring a large Jensen bell when a dangerous temperature was reached. A novelty in signalling for war purposes was also shown in the shape of a Scott's signalling lamp, which is probably one of the greatest improvements of modern times for night signalling at sea. The principle of the telephone was then explained by means of slides and instruments. Electricity as a destructive power formed the next section of the lecture. After showing various illustrations explaining submarine mining and torpedo work, an experiment was made by means of which some loose gunpowder was fired. Electric lighting was the next topic, the immortal experiment of Faraday's, upon which the whole of modern electric lighting and transmission of motive power depends—viz., the fact that a current is produced in a coil of wire when a magnet is suddenly put in or drawn out—was shown by means of a diagram and an experiment. The lecture-room being lit by electricity, the lecturer was able to show an arc lamp in operation, in addition to many interesting specimens of incandescent lamps both for mining and surgical operations, and the present position of lighting from central stations and future developments were dwelt upon. To illustrate the production of electric power for lighting purposes, a hand dynamo was shown in operation, and also an ingenious arrangement for automatically detecting and giving warning of any leakage of electricity by means of an apparatus devised by the lecturer, which every half hour, or more frequently if desired, tests any circuit to which it may be connected, and gives warning should there be leakage both by means of the brilliancy of the lamps and by an alarm bell. Medical electricity formed an interesting topic, and a great novelty was exhibited in the shape of an apparatus destined to be better known, called the dental vibrator. By means of this most simple apparatus, teeth can be extracted without the least pain to the patient. The principle of operation is that a rapidly interrupted current is allowed to pass through the body of the patient who grasps a handle in each hand, while a third connection is made to the forceps, so that a shunt of the current passes through the teeth. There is little doubt that this method of extraction will supersede extractions under other anæsthetics. As a suitable conclusion to the lecture, two beautiful illustrations of transmission of power were given in the shape of a motor of the Immisch type driving a fan, and a working model of a crane of novel construction.

---

* The tension on the insulating material, tending to pierce it with a spark, is proportional to the square of the difference of potentials (per unit thickness) to which the insulating material is subject. It is incorrect to talk about the tension of the conductor, or about the tension of the current; for the tension or electric stress is always an action affecting the dielectric or insulating material.

In concluding, the lecturer remarked that he had to thank Messrs. Woodhouse and Rawson United, Limited, the Electric Construction Corporation, and the General Electric Traction Company, Dr. Silvanus Thompson, Messrs. Appleton, Drugman, Room, and other friends for their kindness in lending apparatus and slides.

No less than 45 slides were shown by means of an oxy-hydrogen lantern, and the experiments throughout were most successful. The whole of the room was lit by means of E.P.S. cells and incandescent lamps.

COMPANIES' MEETINGS.

EASTERN TELEGRAPH COMPANY.

The thirty-seventh half-yearly ordinary general meeting of this Company was held at Winchester House, Old Broad-street, E.C., on Thursday, Sir John Pender, K.C.M.G., chairman, presiding. We give the report of the Directors on the next page.

In the course of his speech the **Chairman** went through the chief items of the report and accounts, congratulating the shareholders upon the success of the Company's operations during the half-year. The expenses in connection with the Paris Telegraph Conference amounted to £981, but they had received full value for their money. The expenses of repairs and renewals of cables amounted to £31,477, against £49,634 for the corresponding period, or a decrease of £18,157. Their cable ships had been employed several times by other companies, and the credits derived thereby had been applied *per contra*. They were able to declare their usual interim dividend of 5 per cent. per annum, and to carry forward £78,195, against £61,151 last year. The Chairman then alluded to the duplicating, triplicating, and even quadrupling of their cables on the Australian route, which had been carried out, and which we referred to in a recent issue—12 had been duplicated, one triplicated, and two quadrupled. This had been done without increasing their capital, at least to any material extent. They had been watching the Dark Continent, in which there was evidence now of renewed activity, and no doubt their traffic would move upwards in sympathy. In conclusion, he moved the adoption of the report and accounts.

This was seconded by the **Marquis of Tweeddale**, and carried unanimously.

The **Marquis of Tweeddale** moved the re-election of Sir John Pender as director in complimentary terms, and **Sir John Pender** moved the re-election of the Marquis of Tweeddale, remarking that he was no fancy director as some people represented, but a man with a good head and great energy. Both these resolutions were duly seconded and carried, as were others re-electing the auditors, Mr. Henry Dever and Messrs. Welton, Jones, and Co., and thanking the Chairman for presiding.

The meeting was fairly well attended, and, as an old shareholder said, was remarkable for its eloquence—the eloquence of silence, which was golden. There were no questions asked.

WOODHOUSE AND RAWSON UNITED.

An extraordinary general meeting of the shareholders of this Company was held on Friday, the 9th inst., at Winchester House, Old Broad-street, E.C., Sir Rawson W. Rawson, C.B., K.C.M.G., in the chair.

The **Secretary** (Mr. Geo. Worrall) having read the notice convening the meeting,

The **Chairman** said ; I am happy, on this occasion, to have the opportunity of repeating the confidence of the Board that the success which has hitherto attended the Company will continue to be maintained. It will be in your recollection that Lord Aberdare stated his opinion to the shareholders very confidently that the capital of the Company was insufficient for the opportunities that it had of realising large profits for excellent and sound undertakings. His colleagues were of the same opinion, and we were prepared at an earlier period than the present to address our shareholders upon that subject if it had not been for the financial crisis which has stopped anything of the kind for some weeks past. There are two objects in the resolutions. The first is to enter into such arrangements as we may think advisable with the liquidators of Woodhouse and Rawson, Limited, for the refunding of the dividend guarantee fund of £75,000 deposited for three years. You will have seen in our balance-sheet for the first year the profits of the year, after paying these rates of dividend to our shareholders, left a surplus of £41,000. That is equal to about a year and a half of our annual payment at these rates to our shareholders. Now, a year and a half has already elapsed of the three years for which the guarantee fund was left in our hands, and it is time that we should consider how that sum is to be repaid. Therefore, we consider it is convenient, when we are asking you to increase our capital for general working purposes, to propose to you, at the same time, an arrangement for repaying that loan upon terms which will be decidedly advantageous to us. We feel confident that the security of our shareholders is perfect as to their 15 per cent. dividend for these three years. One year has elapsed, and we have paid our shoreholders at the rates that we undertook. Another half-year has elapsed also, and our profits have been, I may venture to say, not less than last year. Our expectations of the coming six months are no less favourable. We shall, therefore, at the end of the second year, not only pay our shareholders at the rates of 8 per cent and 15 per cent., but we shall have another surplus to add to the £41,000, wherewith, if necessary, to pay our shareholders for the third year. We are not pledged beyond the third year, but our hopes certainly do extend beyond that period. The second point is that the capital of the Company be increased from the present amount to £550,000. If we have a larger capital we shall be able not only to continue this rate, but to improve it. Our business has largely increased. I have just had put into my hands the earnings of our supply department. The second six months were 50 per cent. over the first six months, and the third six months were 30 per cent. over the second six months. We have to hold in our hands a large and very varied stock of electrical goods to meet the demands of our customers ; and, moreover, we must have a very large outstanding account with several thousand customers. We have already stated to you that we have increased our business by the purchase of one very important and extensive business. We find it necessary that we should manufacture a number of the more important articles required by our customers, so as to be ready to meet their wants without delay, and without the difficulty of procuring them from other people. For that we ask sanction, in order that we may be prepared at the proper time to issue the shares. As regards the debentures, as 6 per cent. is above their proper rate it is our intention to recall them, giving their holders the profit that we promised them at the time of their issue, and issuing probably £200,000 at 5 per cent. That will be a profitable arrangement for the Company ; it will be a profitable arrangement for the shareholder ; it will leave a larger sum available for distribution. As regards the debentures, the holders of them have a largely-increased security. They have the advantage of all the purchases of real property and factories we have made, and in other respects their position will be improved. With regard to our shares, 15 per cent. safely earned, and likely to be continuously earned, ought to place them considerably above par. The delay in the settlement of the affairs of Woodhouse and Rawson, Limited—for, unfortunately, the names are so similar, and now happily settled—the delay in our obtaining our settlement, the last paper for which goes in next week, has combined to lower the value of our shares below their proper figure ; but we feel confident that when our shareholders and the public find that the profits we made last year are not accidental and casual, but will be maintained this year, and have every apparent prospect of continuing during future years, they will have restored confidence in our shares, which will again reach their proper value. We might have called up some of our uncalled capital, but for several reasons this is always undesirable. We have the satisfaction of calling to your notice the success which has attended the Company, both in the matter of the Elmore shares and of the International Okonite shares. Every day confirms the truth of the original statements made with regard to the value of the Elmore process, and the two companies that have been established for foreign countries are only a prelude to more arrangements for the sale of the patent in other countries. The French Company will hold their meeting this afternoon, and I have reason to know that a statement will be laid before the shareholders of that company, which will contain the most satisfactory assurances of the confidence obtained after enquiry by the French members of that Board, that the process is more profitable than has been hitherto held out to the shareholders of the English Company. By arrangements already made they have the expectation of seeing the work on a large scale within the next six months in France, holding out the most satisfactory prospects to the shareholders of that company. The International Okonite have declared an interim dividend of 10 per cent. upon the working of the six months they have been in operation. The certificate of the accountants, Messrs. Price, Waterhouse, and Co., shows that our estimates of earnings for the six months of last year from June and July have been exceeded, and that, it must be borne in mind, has been before the Manchester branch have been able to erect their works, and to commence operations under the Okonite patent in England. Consequently, the success of the International Okonite Company, as far as profits are concerned, is substantiated to the fullest. These are companies in which we have been interested, and that will give you an indication of the class of enterprises that Woodhouse and Rawson United desire to be connected with—no untried schemes, no chance patents, but businesses, patents, and processes that we, with our numerous staff, scientific and financial, and with the variety of factories that we can boast of, are able to thoroughly investigate and test. I move: "That the Directors be authorised to enter into such arrangement as they shall think advisable with the liquidators of Woodhouse and Rawson, Limited, for the immediate or early repayment to such liquidators of the sum of £75,000, or any part thereof, deposited with the Company on the terms that it should be retained till July 1, 1892, as a dividend guarantee fund."

This was seconded by **Sir Edward Thornton.**

In answer to questions, **Mr. F. L. Rawson** (managing director) said the prospects of the business were very good. The Company might have been thought to be speculative in purchasing so many as four businesses in so short a time as 18 months, but what they wanted to do was to put themselves in the position of being able to manufacture and supply creditably to themselves and profitably also to their clients every class of electrical goods. That they were able to do now, with the exception of cable wire, which was a speciality manufactured and sold by itself, and the businesses had turned out very well. In one of them, where they were, perhaps, a little doubtful, they had received an important commission from the Government, which he hoped would turn out very profitably indeed, and result in large future orders. With regard to new companies, as a rule they were connected with a business for one or two years before they brought it out. They gradually built them up, so that they were not really new when they brought them out. With regard to the repayment of the £75,000, they proposed, by their arrangement with the liquidators, to pay this amount in cash or debentures, and they would naturally pay them in the very most advantageous way to the Company. If they gave them the £75,000 in 5 per cent. debentures, it only added £3,750 per annum to their expenditure, which was a very small amount out of a margin of profit £41,000 as last year. With regard to the dividend guarantee fund, the Chairman had told the shareholders that they proposed to pay an interim dividend, as they had already this half-year earned more than enough to pay the dividend for the whole year. They had the £41,000 margin last year; so that really they could not take more than a very small portion out of the dividend guarantee fund in any event. Their profits were now so large, and the increase in the use of electricity was so great, that there was no necessity for going into speculative matters, and he did not think that practically there was a single piece of business into which they had gone that had involved them in a liability of even £10,000. He thought that the manufacturing profits would be considerably larger this year than last. It was rather risky making a guess, but he would not be surprised if they amounted to £10,000 or £12,000 more than last year. The shareholders would be glad to hear that now a very different and better class of business was being offered to them than before.

The resolution was carried unanimously.

The **Chairman** then moved: "That the capital of the Company be increased to £550,000, by the creation of 40,000 new shares of £5 each, of which 20,000 shares shall be preference shares, which shall be entitled to the same preferential dividend and rights, other than the benefit of the dividend guarantee fund, and shall be subject to the same conditions as, and rank for all purposes *pari passu* with, the existing issue of 30,000 preference shares of £5 each of the Company; the remaining 20,000 shares shall be ordinary shares, and shall be entitled to the same dividends and rights, other than the benefit of the dividend guarantee fund, and shall be subject to the same conditions as, and rank for all purposes *pari passu* with, the existing 40,000 ordinary shares of the Company."

This was seconded by **Mr. Philip Rawson** and carried. The usual vote of thanks to the Chairman brought the meeting to a close.

ELMORE'S FRENCH COPPER COMPANY.

The first general meeting of this Company was held on Friday afternoon, 9th inst., at the Cannon-street Hotel, Sir Richard Meade, K.C.S.I. (chairman of the Company) presiding.

The **Chairman** explained that this was only a statutory meeting of the Company, held to fulfil the requirements of the Companies Acts, and not for the transaction of business. They proposed, however, to ask the meeting to sanction certain alterations in the articles of association, of which due intimation was given in the notice convening the meeting, and which were required by the Committee of the Stock Exchange. He stated that the 66,750 shares offered to the public were applied for about four times over, and that a full allotment was made among some 2,000 applicants. The sums due on allotment had, with a small exception, been all paid up, and those still outstanding on the first and final calls were in course of adjustment. The Stock Exchange Committee had granted a settlement for their shares, and, provided this meeting passed the alterations in the articles of association, there would be an official quotation of their shares on the Stock Exchange at a very early date. Steps were also being taken to introduce their shares upon the Paris Bourse. The Directors congratulated the shareholders on having been able to secure the very valuable services of M. Eugene Secrétan, formerly manager of the largest copper manufacturing industry in the world, as the Company's general manager in France. Acting on his recommendation they had decided to establish works in the North of France, and M. Secrétan told them that these would be in operation by 1st July. For this purpose they had applied to the Elmore Foreign Company to lend them £50,000 at 6 per cent. for three years.

M. Secretan made a statement in French, an English version of which was supplied, and said that the new buildings would be handed over to the Company at the end of April, and on the 1st July their works, which were constructed for an output of 370 tons of copper articles per month, would begin work. The sale of these articles was absolutely assured.

In reply to several questions, the **Chairman** said he was informed that the Foreign Elmore Company, which had lent the £50,000 on debentures, would be very glad to issue those debentures to any shareholders of the French Company who were willing to take them up. It had been impossible for the Directors to enter into any part and parcelling in regard to the debentures. The great object they had in view was to secure the possession of a sufficient sum of money to enable them to start, what M. Secrétan assured them was necessary for the success of the Company. They could only do that by accepting the arrangement offered by the Foreign Company to give them the £50,000. A question had been asked about the use of water power at Bellegarde, but he had explained that matter to the meeting. They had secured a site at Bellegarde with water power, but it was impossible for them to commence two manufactories at once, and the weight of evidence in favour of starting in the first instance in the North of France was so conclusive that they were compelled for the present to put Bellegarde aside; but they still retained their interest at Bellegarde, and when the proper time came, and they had money sufficient to try a second factory, they proposed to start there.

Formal resolutions relating to alterations in the articles of the Company required by the Stock Exchange Committee were then passed.

COMPANIES' REPORTS.

EASTERN TELEGRAPH COMPANY.

Report of the Directors, for the half-year ended September 30, 1890, presented to the thirty-seventh half-yearly ordinary general meeting, held at Winchester House, 50, Old Broad-street, E.C., on the 15th inst.

The Directors submit the accounts and balance-sheet for the six months ended September 30, 1890. The revenue for the period amounted to £352,873. 11s. 1d., from which are deducted £91,723 11s. 7d. for the ordinary expenses and £31,477. 17s. 9d. for expenditure relating to repairs and renewals of cables, etc., during the half-year. After providing £5,212. 8s. 2d. for income tax, there remains a balance of £224,459. 13s. 7d., to which is added £2,484. 9s. 7d. brought from the preceding half-year, making a total available balance of £226,944. 3s. 2d. From this balance there have been paid:

	£	s.	d.
Interest on debentures and debenture stock	28,274	13	0
Dividend on preference shares.............. ...	20,474	3	9
Two interim dividends of 2s. 6d. per share each on ordinary shares........................	100,000	0	0
	£148,748	16	9

Leaving a balance of £78,195. 6s. 5d., which is carried forward to the next account. The revenue includes £33,455. 17s. 8d. dividends for the half-year upon the Company's shares in the Eastern and South African, the Black Sea, the Direct Spanish, and the African Direct Telegraph Companies. The Directors learn that the negotiations referred to at the last general meeting with certain of the Australasian colonies for effecting a reduction in the tariff will be speedily concluded, and the new rates will be brought into operation at an early date. The Directors have decided in view of a largely-increased traffic with Australasia, to lay a triplicate line from Aden to Bombay, and have entered into a contract with the Telegraph Construction and Maintenance Company for the manufacture and laying of the cable early in the present year. The new Red Sea cable connecting Suez, Perim, and Aden, referred to in the last report, was successfully laid by the contractors in November last. Arrangements have been made to take the direct Suez-Aden 1876 cable into Suakim, thus duplicating the Suakim-Suez section, and adding to the security of submarine telegraph communication with that port. In accordance with the articles of association two of the Directors, Sir John Pender, K.C.M.G., and the Marquis of Tweedale, retire by rotation at this meeting, and, being eligible, offer themselves for re-election. The auditors, Mr. Henry Dever and Messrs. Welton, Jones, and Co., retire, and offer themselves for re-election.

DIRECT UNITED STATES CABLE COMPANY.

The report of the Directors for the six months ended Dec. 31 states that the revenue (subject to revision on decision of the case mentioned below), after deducting out payments, amounted to £43,347, against £42,357 for the corresponding period of 1889. The working and other expenses for the half-year, with income tax, and including the expenses of the New York office entirely borne by this Company, but exclusively of cost of repairs of cable, amounted to £17,556, leaving a balance of £25,791 as the net profit, making with £968 brought forward from the previous half-year a total of £26,759. For the corresponding period of 1889 the working expenses and other payments amounted to £15,509. Interim dividends of 3s. 6d. per share for the quarter ended Sept. 30, and of 3s. 6d. per share for the quarter ended December 31, together amounting to £21,248, have been declared, £5,511 being carried forward. In the case of the Anglo-American Telegraph Company *v.* Compagnie Française du Télégraphe de Paris à New York, the appeal to the Council of State, mentioned in the report to June 30, 1889, is, it is stated, still pending.

CITY NOTES.

City and South London Railway.—The receipts for the week ended January 10 amounted to £748.

Brazilian Submarine Telegraph Company.—The receipts for the week ended January 9 amounted to £5,487.

St. James's and Pall Mall Electric Light Company.—Mr. Egerton H. Clarke has joined the Board of this Company.

Commercial Cable Company.—A telegram from New York says that Mr. Hector De Castro has resigned the vice-presidency of this Company in order to become the secretary of the Inter-Continental Railway Commission.

Western and Brazilian Telegraph Company.—The receipts for the week ended January 9, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £4,434.

Venezuela Telephone Company.—The Company notifies the payment of an interim dividend at the rate of 3 per cent. per annum. The Stock Exchange have appointed to-day (Friday) a special settling day in the shares 1 to 13,144 and debentures 1 to 572.

Electric Construction Corporation. — The Corporation announces an issue of £100,000 six per cent. first mortgage debentures (part of a total issue of £150,000), redeemable at par on January 15, 1901, or at £106, at the option of the Corporation, on six months' notice, after January 15, 1894. The International Trustee, Assets, and Debenture Corporation, Limited, is authorised to receive subscriptions, at par, for the above-mentioned debentures. This issue is made in consequence of the growth of the business of the Corporation, and for the purpose of extending its operations and repaying a banker's advance of £30,000 (secured by temporary debentures), which has enabled the Corporation to complete and equip its new works at Bushbury, Wolverhampton.

PROVISIONAL PATENTS, 1891.

JANUARY 5.

176. **Improvements in electric dynamos and motors.** William Terrell Garnett, Sunbridge-chambers, Bradford.
184. **Improvements in armatures of dynamo machines.** Rookes Evelyn Bell Crompton, 55, Chancery-lane, London.
185. **Improvements in dynamo machines.** Rookes Evelyn Bell Crompton, 55, Chancery-lane, London.
200. **Improvements in or connected with electric arc lamps.** Lucien Brianne, 4, South-street, Finsbury, London.

JANUARY 6.

223. **Improvements in primary electrical batteries.** William Henry Todd, 1, St. James's-square, Manchester.
230. **Improved mechanism for actuating clocks by electricity.** Frank Schwartz, Monument-chambers, King William-street, London.
244. **A wire guard for electric lamps.** Charles Harrison, 136, Kentish Town-road, London.
248. **Improvements in mechanism for transferring electric car batteries.** Frederick Gleason Corning, 76, Chancery-lane, London. (Date applied for under Patents Act, 1883, Sec. 103, 9th June, 1890, being date of application in United States.) (Complete specification.)
258. **Improvements in electric arc lamps.** Albert Gay and Robert Hammond, 46, Lincoln's-inn-fields, London.
271. **Improvements connected with electric arc lamps.** Albert Schoenerstedt, 166, Fleet-street, London.
284. **A new or improved telephone transmitter.** Erhard Ludwig Mayer, Norfolk House, Norfolk-street, London.
285. **A new or improved method of telephonic transmission and apparatus therefor.** Erhard Ludwig Mayer, Norfolk House, Norfolk-street, London.

JANUARY 7.

303. **Improvements in electric railway systems.** Charles K. Harding, 46, Lincoln's-inn-fields, London. (Date applied for under Patents Act 1883, Sec. 103, 9th June, 1890, being date of application in United States.) (Complete specification.)
309. **Obtaining electricity by waste water power.** Nicholas Parascho and Constantine Constantinides, 5, Herne-road, Chiswick.

JANUARY 8.

361. **Improvements in dynamo-electric machines.** Francis William Webb and Arthur Moore Thompson, Holly Bank, Crewe.
389. **Improvements in electricity meters.** Francis Teague, 433, Strand, London.
394. **Improvements in electric measuring instruments.** Walter Thomas Goolden and Sydney Evershed, Woodfield Works, Harrow-road, London.

JANUARY 9.

439. **Improvements in torpedoes propelled and steered by electricity.** Benjamin Joseph Barnard Mills, 23, Southampton-buildings, London. (Winfield Scott Sims, United States).

JANUARY 10.

475. **The absolute silence of telephone, telegraph, and other wires, whether attached to chimneys, buildings, iron standards on roofs, or wooden poles placed in any position.** Alfred Evan David Walters, 12, Hudson-road, Southsea.
476. **Wire coupling for electrical conductors.** William Edgar Banta, 62, St. Vincent-street, Glasgow. (Date applied for under Patents Act, 1883, Sec. 103, 11th June, 1890, being date of application in United States.) (Complete specification.)
490. **Improvements in construction of electric batteries for application to the firing of firearms and other explosive appliances.** Sally Adolf Rosenthal and William Smethurst, 1, Gresham-buildings, London.
492. **A jointed bracket for electric lamps.** Robert Williamson, 54, Fleet-street, London.
508. **An improved underground electric conduit.** William Henry Munns, 106, Victoria-chambers, Chancery-lane, London. (Homer Young, United States.)
536. **Improvements in dynamo-electric generators and motors.** Claude William Atkinson and Llewelyn Birchall Atkinson, 1, Queen Victoria-street, London. (Complete specification).

SPECIFICATIONS PUBLISHED.

1888.

12594. **Phonographs.** Gourad (Edison). 11d. (Second edition.)

1889.

1101. **Electric conductors.** Lowrie and Hall. 8d. (Second edition.)

NOTES.

The Dover-Calais Cable broke on the 16th inst.

Prof. Ewing.—It is stated that a Cambridge University honorary degree will be conferred upon Prof. Ewing.

Hanley.—The Town Council have approved the draft of their provisional order and decided to deposit £50 with the Board of Trade.

Ice Carnival.—At Cambridge last week ice carnivals were held on the flooded and frozen meadows under the brilliant rays of the electric light.

Telegraph Extension in Africa.—The British East Africa Company have opened a coast telegraph line between Mombassa and Melindi, 70 miles north.

South American Cables.—The s.s. "Silvertown" completed, on January 15th, the Chorillos-Yquique section of the new Central and South American Co.'s cables between Chorillos, Yquique, and Valparaiso.

Lowestoft.—The Town Council are thinking of going in for an order. The gas supply is not in their hands, and the company won't reduce the price when asked to. Hence the raising up of the electric light bogey.

Eastbourne. —Compton-place House, Eastbourne, is being prepared as a residence for Lord Hartington. Extensive alterations have been made in the house and grounds, and the mansion and stables will be lighted electrically.

The Rubber Syndicate.—A telegram from New York dated Saturday, says, quoting news received from Para, that the subscription to the new Rubber Syndicate on the first day was £2,000,000. The whole amount will be called for.

Royal Society.—Last evening the following papers were to be read before the society—viz., H. Wilde, F.R.S., on the "Unsymmetrical Distribution of Terrestrial Magnetism," and T. Andrews, F.R.S., the "Passive State of Iron and Steel," part two.

Camberwell.—The Vestry have given their consent to the application of the Camberwell and Islington Electric Light and Power Supply Company for obtaining an order to supply electricity in East Dulwich, Peckham, Nunhead, Camberwell, Denmark Hill, and old Kent-road.

Sunderland.—A special meeting of the Town Council has been summoned for February 16, to consider the advisability of making application to the Board of Trade for a provisional order under the Electric Lighting Acts, 1882 and 1888, for the supply of electricity within the borough.

Naval Ball at Plymouth.—The barracks at Keyham, where the naval ball is to be held to-night, have been lighted electrically. The current is to be supplied from the cruiser "Racoon," which lies at anchor off the barracks. No less than 1,600 yards of cable have been used for conveying the current from the ship to the shore.

Overhead Wires. —The Newington Vestry have decided to convey to the Local Government Board their opinion that the control of all subways and overhead wires should be placed under the control of the London County Council, and not under the district councils, as suggested in the memorial from the Strand District Board.

New French Cables.—Early this year the Société Française des Télégraphes Sous Marins will lay two cables, from Paramaribo to Cayenne, and from Cayenne to Vizen (Para). These cables connect French Guiana and the general international telegraphic system, and will put Brazil and the other countries of Southern America in direct communication with North America.

Hebden Bridge (Lancs.).—The telephone has been adopted as a means of communication between the central and branch co-operative stores at Hebden Bridge. The board of managers of the local co-operative society have just decided to have their several country branches connected with the central premises, and they have accepted the tender of Mr. R. S. Blackburn, electrician, of that town, who has the work in hand.

Paris-London Telephone Line.—It is stated that the telephone service between Paris and London will not be inaugurated until March 1. The cable will be immersed on February 15, and the official trials will last until the end of the month. The tariff has been definitely fixed at 10f. for three minutes' use of the telephone. It is also stated that M. Carnot and the Queen will formally inaugurate the cable by exchanging greetings over the line.

Private Installation.—The Marquis of Londonderry has decided to light Wynyard, his residence in the county of Durham. No less than 750 incandescent lamps will be employed, and the plant will comprise steam engines and dynamos of some 100 h.p. in the aggregate. The contract for the installation has been placed with Messrs. Drake and Gorham, who will carry out the work under the superintendence of Mr. A. A. Campbell Swinton as consulting engineer.

More Direct Wires.—At the last meeting of the Plymouth County Council, the town clerk announced that the Mayor and himself had had an interview with the head of the telegraph department at the General Post Office, and presented the memorial from the Council in support of the provision of a direct telegraph wire between Devonport and London. The official said the matter had already been enquired into, but the memorial would receive attention.

A Submarine Cannon.—News from Rome mentions that experiments have been made in Lake Como with a submarine cannon invented by Signor Toselli, which can be fired at any depth. The odd thing about this gun is that it can be discharged without the use of electricity. Hitherto none of these submarine wonders have been perfect unless electricity played some part in their working. We are afraid Signor Toselli has omitted a most attractive and gold-alluring agent from his subaqueous peace preserver.

Private Bills.—Among the Bills that have passed the examiners at the House of Commons are the Overhead Wires Bill of the London County Council, and a Bill by the Gas Light and Coke Company to remove doubts as to their power to enter premises of the consumer to disconnect the gas, and empowering them, after giving 24 hours' notice, to enter the premises of any consumer between the hours of nine and four if he has ceased to take or require a supply of gas, or has neglected to pay the rent due to the company, and to disconnect the service pipe.

Electric Railway for New York.—A telegram from New York, dated 20th inst., says: "A company has been formed here, with 3,000,000dols. capital, to carry out a scheme for connecting New York City, Brooklyn, Jersey City, and Harlem by a tunnel and a service of electric trains. Mr. Austin Corbin and other very wealthy financiers are promoting the scheme. It is intended to be a practical solution of the rapid transit problem, and will extend both sides of New York City by connecting Brooklyn and Jersey City near Castle Garden.'

Prof. Tyndall.—After the disquieting paragraphs with reference to Prof. Tyndall's health that have been appearing in the daily press, we are very glad to see a letter from his own pen, dated the 20th inst., in which he says: "Since my return from Switzerland, in October, I have been much knocked about by sleeplessness, added to which, later on, I have had to endure the tortures associated with severe inflammation of the veins of one leg. But the worst is now past. I am under the care of a sagacious London physician, who on visiting me yesterday reported most favourably on my progress."

School of Electrical Engineering.—We are informed that Mr. Leon Drugman, M.Inst.E.E., manager of this school, has obtained the consent of Sir Samuel Canning, M.I.C.E., M.I.E.E., Messrs. P. Herbert Carpenter, D.Sc.F.R.S., Gisbert Kapp, M.I.C.E., M.I.E.E., and Prof. Alex. B. W. Kennedy, F.R.S., vice-president Inst.M.E., to form a permanent "consulting committee," who will have the control of the teaching of the school. After having had to record a month ago the untimely death of Mr. W. Lant Carpenter, we can now congratulate the school upon having secured the valuable co-operation of professional men of such high standing.

Dorking.—At the last meeting of the Local Board Mr. Clift, chairman of the Electric Lighting Committee, stated that the committee had not yet prepared a report to present to the Board. They had visited several towns, and there were others they contemplated visiting, and they would reserve their report until they had been to these places. Some members of the committee had been to Woking, and met with a courteous reception from the manager of the works. The surveyor had been to Godalming, and the committee to Chelmsford, where they met with a pleasant reception. They saw the whole of the works, and received such information as it was possible to get.

The London Eiffel Tower.—The report of the Metropolitan Railway contains the following paragraph relating to the proposed tower at Wembley Park: "The Tower Company, Limited, having secured the Wembley Park Estate, situate between Neasden and Harrow, and about six miles from Baker-street, entered into an obligation with this company to offer £60,000 of their share capital to Metropolitan proprietors, and to set aside an additional £40,000 of their capital to meet any further applications. The whole of the £60,000 has been taken up, and applications for additional shares have been received. The station stipulated to be erected at Wembley Park is in course of construction, and will be completed very shortly."

Increase in Telegraph Business.—The enormous increase in the telegraph business within the bounds of the metropolis has necessitated a large increase in the staff outside the Central Telegraph Office. Various offices are finding it impossible to cope with the amount of work now falling to their share, and appointments have been offered to many candidates who were unsuccessful in the last examination for male telegraph learnerships. An intimation has been given that in all future examinations only the highest successful candidates will be trained for the central office, the remainder being drafted to offices within the London postal district, in which the pay is the same, although the prospects of promotion are more remote.

Exhibition at Palermo.—It is proposed to hold a national exhibition in Palermo from November, 1891, to May, 1892. There will be an international section for engines and machinery relating to small industries such as are carried on in small workshops or dwellings. The demand for engines and machines that can be introduced into such places with safety is very great and increasing in Italy, and it is reasonably expected that manufacturers of this class of goods will receive material advantage by taking part in the exhibition. The executive committee has already succeeded in obtaining a considerable reduction in the freights for exhibits, and further negotiations are still going on in this direction. Information can be obtained at the Italian Chamber of Commerce, 4, St. Mary Axe, E.C.

Bradford (Yorks.).—At the last meeting of the Corporation it appeared from the minutes of the Gas and Electricity Supply Committee that the gas works are to be enlarged. As regards electric light work, Mr. Cowgill said he had heard that all street work in connection with electric lighting was done by the Corporation's workmen, and was superintended by a Corporation foreman. He therefore desired to know whether Mr. Shoolbred obtained a commission upon the cost of the works that were executed in this way. Alderman Priestman said Mr. Shoolbred had been paid ever since the electric lighting works commenced a sum of 3 per cent. upon the outlay. Whether this percentage was allowed upon expenditure in the streets he could not at the moment say.

Destroying Microbes.—Several attempts have been made to destroy microbes by the electric current, but not with much success, says the *Globe*. Schiel tried it in 1875, and finding that the bacteria ceased to move under the action of the current, too hastily concluded that they were dead. Cohn and Bonno-Mendelsohnn showed that they were not dead, but only sterile. They succeeded, however, in killing the microbe by long-continued currents in the nutritive solution. Three Marie-Davey cells applied for 24 hours were found to destroy the bacteria, but a doubt remained as to whether they were killed by the electricity or poisoned by the electrolytic changes produced in the solution by the current. Recent experiments of Apostoli and Laguerriere, and also by Prochownick and Spoeth have not resolved this doubt.

The Barking Traction Station.—On Monday, the 19th inst., the St. Luke's Vestry, accompanied by Mr. M. C. Meaby, the surveyor to the Vestry, and Mr. J. W. Ransom, the engineer of the North Metropolitan Tramways Company, visited the General Electric Power and Traction Company's electric cars and installation on the Barking-road section of the North Metropolitan Tramways Company's system. Having made a minute inspection of the many points of interest in the working of the cars, the Vestry expressed themselves as greatly pleased at all they had seen. The tramway company having signified their intention to run electric cars from Stamford-hill to Moorgate-street, and as this Vestry controls that portion of the route which includes Moorgate-street, their inspection was on that account most exhaustive.

The Woodward Storage Battery.—As we believe we were the first technical journal in this country who called attention to the Woodward storage system, we have naturally watched its progress with interest in the States. Dr. Woodward has recently secured patents in this country for a new form of cell which opens up an entirely new departure from the grid form of plate hitherto used. The new type is in the shape of a perforated cylinder, and batteries are being specially manufactured with a capacity up to 2,000 ampere-hours output. We learn that Dr. Woodward has arrived in this country with the intention of establishing works in England to fully develop the Woodward system in Europe. We are promised a full description of the method of manufacture of this the new type cell, which we shall describe in an early issue.

London Chamber of Commerce.—A meeting of the Electrical and Allied Trades' Section Committee will be held on Monday next at 4 p.m. The following is the agenda: 1. Board of Trade provisional orders in regard to telephones, suggested modifications in. 2. Board of Trade rules and regulations *re* overhead wires, report of sub-committee. 3. Board of Trade forms of accounts, report of sub-committee on. 4. Board of Trade Electrical Standards Committee, correspondence in connection with. 5. Proposed exhibition in London of electrical appliances, letter from Mr. Seymour Wade. 6. St. Pancras Electrical Exhibition, letter from Messrs. W. T. Goolden and Co. 7. Automatic electric railway signalling, letter from Mr. Martin Perls proposing address on "Is railway travelling safe as managed at present?" 8. Other matters.

Our Warships' Compasses.—A writer signing himself "R.N., Retired," says, in a recent issue of the *Western Morning News*: "I have just been reading an account of the narrow escape of the 'Serapis' off Ushant. Surely there must be something to account for her getting so much out of her course besides current. My belief is that the fault is to be found in the compasses supplied to our men-of-war. They are far too small to steer by. Going on board a man-of-war from a merchant steamer, they always look to me ridiculous. How is it that all our large ocean liners and most merchant steamers have adopted large steering compasses? Why, because they have found them absolutely necessary if they want to make their course. Nearly all of them now steer to degrees, and not quarter-points, which is found not to be correct enough in a long day's run. Steering to a degree is impossible with the small compasses used in our men-of-war. I know that small compasses are supposed to be the best in theory, but then theory and practice in all cases don't fit in, and this seems to me to be one of them."

Royal Meteorological Society.—The annual meeting of this society was held on Wednesday, the 21st inst., at the Institution of Civil Engineers, 25, Great George-street, Westminster, Mr. W. H. Dines, B.A., vice-president, in the chair. The report of the council stated that the progress of the society during the past year had been of a satisfactory character. Among the investigations carried on by the society are the following: The organisation of a large number of meteorological stations, the observations from which are examined and reduced by the staff, and printed in the *Meteorological Record*; the regular inspection of these stations by the assistant secretary; the collection and discussion of phenological observations; and an enquiry into the thunderstorms of 1888 and 1889. An exhibition of instruments is held annually in March. During the year a complete catalogue of the library, extending to 222 pages, has been compiled and published. The library has so much overgrown the present limited accommodation, that the council have been obliged to consider the question of obtaining more commodious rooms, and have consequently inaugurated a "New Premises Fund," which is being well supported by the Fellows.

Electro-Harmonic Society.—A smoking concert will be held on Friday next at the St. James's Hall Restaurant (Banquet-room), Regent-street, W., at 8 o'clock. The following is the programme:—Part 1: Glee, Messrs. J. Brown, A. Thompson, W. G. Forington and R. Hilton; new song, "Thoughts and Tears" (Hope Temple), Mr. W. G. Forington; pianoforte solo, "Prelude and Fugue in G minor" (Bach-Liszt), Mr. Alfred Izard; song, "The Banks of the Bann" (E. German), Mr. Arthur Thompson; glee, Messrs. J Brown, A. Thompson, W. G. Forington, and R. Hilton; violoncello solo, "Second Morceau de Salon" (Albert), Monsieur B. Albert; song, "Hybrias, the Cretan" (J. W. Elliott), Mr. Robert Hilton; humorous sketch, Mr. James Kift. Part II.: Glee, Messrs. J. Brown, A. Thompson, W. G. Forington, and R. Hilton; song, "Weep no more, thou sorry boy" (Hatton), Mr. W. G. Forington; serenade, "Neapolitan song" (Tosti), Mr. Arthur Thompson; violoncello solos (a) "Marche Villageoise" (Albert), (b) "Etude Caprice" (Goltermann), Monsieur B. Albert; glee, Messrs. J. Brown, A. Thompson, W. G. Forington, and R. Hilton; old song, "Now Phœbus" (Dr. Arne), Mr. Robert Hilton; humorous sketch, Mr. J. Kift.

Music by Telephone.—At the Midland Institute *conversazione* last week, the National Telephone Company fitted up four rooms in the institute building, connected with London (125 miles), Liverpool (140 miles), Manchester (93 miles), and Bradford (125 miles). The rooms were each fitted to accommodate 32 listeners, so that 128 people at one time could enjoy musical performances going on in four far distant towns. Over the London wire came first, between seven o'clock and half-past eight, the strains of a concert. Then the wire was turned on to the Savoy Theatre to hear "The Gondoliers," with such success that everyone was very loth to withdraw from the telephone until the curtain fell in London. In an adjoining room could be heard from Manchester, now "Aladdin" from the Theatre Royal, now "Bo Peep" from the Prince's. From Bradford came the sounds of a concert, while in the next room the telephones recorded the performance at the Court and Prince of Wales's Theatres, Liverpool. The amusement was not confined to the listeners, for by-standers derived considerable fun from the wagging of heads, beating of time, and other (practically) unconscious demonstrations of approval of the various performances by those in possession of the telephones.

Stafford.—The Electric Lighting Committee of the Town Council have sent out circulars to likely consumers within their area, requesting them to state, before the 31st inst., if they wish to have a supply of electricity for lighting purposes, the kind of premises to be served, the number of lights, and whether the supply is to be under contract or by measurement. The committee have fixed the price at 7d. per Board of Trade unit if the supply is by meter, or 40s. per annum for each 16-c.p. incandescent lamp if by contract, which the committee now recommend, except in special cases where a large number of lights are required. The committee put the equivalent price of gas at 5s. 10d. per 1,000 cubic feet. It is estimated that the cost of supplying and fixing the necessary inside wiring, internal fittings, and lamps will be about £1. 5s. per light; but the figure will vary according to the number and decorative nature of the fittings adopted. This expense the consumer will be required to bear. The service supply on public ground will, as in the case of gas, be put in free; but where consumers prefer to pay by measurement, they will be required to provide their own meter. The electric lighting service is under the direction of Mr. J. Ferguson Bell, the gas engineer of the Corporation.

German Telegraph Tariffs.—On the advice of Herr von Stephan, the Imperial Government has again reduced the tariff for telegrams within Germany, this time from six to five pfennigs a word, with a minimum charge of 50 pfennigs, or 6d., for any message, however brief. Herr von Stephan declares, however, that he sees no good and sufficient reason to yield to the demand of 234 newspapers which have petitioned for a reduced tariff for Press telegrams. These newspapers, he says, have already enjoyed advantages enough in the lowness of the rates for their postal transmission, as well as in the comparative cheapness of the wires of which they might have the special use overnight. Of over 14 million telegrams that were last year sent and delivered within the Empire only 1·29 per cent. were Press messages, representing a revenue to the State of about 153,000 marks, or £7,600. If the Press are granted a special price for telegrams, charitable societies, universities, etc., will be sure to follow suit with similar requests for exceptional treatment which can never be accorded. The present tariff, the German Postmaster-General thinks, is not too high, as witness the many unnecessary telegrams which the newspapers print. This is very unkind of Herr von Stephan, but it is also very true.

Institution of Electrical Engineers.—On Thursday week the hall of the Institution of Civil Engineers was crammed with electrical men—and women—anxious to hear what Mr. Wm. Crookes had to say on "Electricity in Transitu: from Plenum to Vacuum," which was the subject of his presidential address. Prior to the address a hearty vote of thanks was accorded to Dr. John Hopkinson, last year's president, on the motion of Mr. Alexander Siemens, seconded by Mr. Kapp, after which Mr. Crookes took possession of the vacant chair amid enthusiastic manifestations of approval. The address, which we gave in full last week, was listened to with the deepest attention from first to last, though to do so necessitated a very considerable exercise of mental power over some two hours of time. The experiments demonstrating the theories expounded were very beautiful, and with but one or two exceptions (unavoidable in each case) very successful. Mr. Gardner thoroughly deserved the ecomiums bestowed on him by Prof. Crookes for the care with which he had prepared them. At the conclusion of the address, Sir Wm. Thomson, with characteristic enthusiasm, proposed a vote of thanks to the President, which was seconded by Mr. W. H. Preece, and carried by acclamation. We may confidently say that this address marks an era in the history of the Institution of Electrical Engineers.

James Watt Anniversary.—A dinner to commemorate the memory of James Watt was held in Glasgow on Monday night, under the auspices of the Philosophical Society and the Institute of Engineers and Shipbuilders, Prof. McKendrick in the chair. In the course of proposing "The memory of James Watt," the chairman said: "Were James Watt suddenly to appear in one of our engineering lecture-rooms, he would probably be much mystified by references to the principles of thermo-dynamics and the theory of steam, but he would find the fundamental experiments much the same as when he left the earth nearly 72 years ago." Later on he prophesied that "the time might come when tidal-power, river-power, waterfall-power, wind-power, and even the power of the sun's rays, would be utilised, and mechanical contrivances of all kinds—railways, ships, machinery—would be driven by electrical energy stored by contrivances already invented but yet far from perfect. After comparing the amount of energy got out of man as compared with the steam engine, and showing how economical nature was in the production of energy, as illustrated in the electric fish, fire-flies, and glow-worms, he remarked that it was not too much to hope that we might find how nature produced these effects on a small scale, and then we might be able to imitate them on a large scale, and with an economy to which we would be driven when obliged to stop our present rate of extravagant expenditure."

Labour Exhibition.—We have received the prospectus of "The World's Labour Exhibition" which it is proposed to hold in London this year. Elsewhere in this issue Mr. S. F. Walker is railing against exhibitions, and we are sure that in a great measure he echoes the sentiments of exhibitors. We may not agree with all he says, but of the main fact that exhibitions have been overdone there will be no denial. Nine-tenths of the exhibitions at the present time are organised because the promoters hope thereby to earn easily a good sum of money. To us this prospectus of a labour exhibition is so much clap-trap. It will be interesting to find someone looking behind the scenes and telling us how far the promoters can be termed "labourers." England seems to be a happy hunting ground with people who have un-English names, but is it not almost time that this exploitation should cease? Not to know men shows oneself to be unknown, yet, notwithstanding this drawback, who is Mr. A. Louis D. de Lavigerie, the secretary, and his co-promoters? So far as we can see, the sole object of this, as of most schemes, is to make money. Co-operators and trade unionists are to be appealed to, and, no doubt, will have to provide guarantee funds, if the affair is carried out, and it is almost as certain that such funds will have to be paid, for except the Cours d'Armour, Jeux Floraux, Kermesses et Pardons, etc., there seems to be little that is attractive in this latest proposal. Since writing the above a meeting has been held in connection with this exhibition, with the result that the promoters have been supplanted by a committee of trades unionists with whom we have no more sympathy than with their un-English *confrères*, or would-be *confrères*.

A New Sounding Machine.—Mr. S. H. James, C.E., has brought out a new sounding machine which consists of a sinker so shaped and slung that it descends to a certain position for much the same reason that a kite ascends; and having descended to its proper depth it remains there, following the ship without deviation. Attached to a slip-hook fastening to the sling of the sinker is a vertical iron lever, having a cup at its lower end for the arming or grease. A reel of wire, which is secured to the vessel's taffrail, is slung so as to be capable of swinging like a ship's bell. The vibration of the wire, owing to the great strain of towing the sinker, is very marked, and the very best wire is used. Use is made of this vibration, and the aid of a sounding-box, to indicate that the sinker is towing correctly. The action is as follows: The kite or sinker is first slung according to instructions; some arming is put in the cup, and the sinker then lowered to the surface of the water. Then, easing out the wire tow-line rapidly by means of a brake, the heavy end of the sinker dips; the strain of the passing water acts on the whole, and it goes down to its position, the sounding-box immediately setting up a rattle. On running into the depth set for, the cup-lever strikes the bottom, releases the sling of the kite, which then floats at once on the surface. The rattle of the sounding-box ceases: the wire reel, which is heavy for its size, having been pulled out of the perpendicular by the strain on the wire, now flies back and strikes a gong. The look-out man attending the machine reports that the rattle has ceased, or that the gong has struck. The ship's speed is slowed, and the sounding, perhaps, verified by a cast of the lead taken either with the same machine or with a hand-line. Mr. James's machine, which, by the way, is called the "sentry," has been tried by a coasting steamer in a run from Glasgow to London, and, we understand, gave satisfactory results. Is is also being tested on board H.M.S. "Rambler," surveying ship, in the Red Sea. Independent soundings with the ordinary lead line have been taken in cases where the "Sentry" has given an alarm, and its action has been verified as correct.

South Kensington and Paddington Railway Profs. Ayrton and Rücker have been making experiments to show the extent to which the proposed electric underground railway with this title is likely to affect the instruments at the Central Institution, and Prof. Ayrton has written to the *Times* on the subject. We make the following extract from his letter: "It may be mentioned that we did not employ any very delicate instruments, such as are necessary for physical research, but only the ordinary rough apparatus that is in daily use by students in a modern physical laboratory. Even such rough apparatus is seriously affected by mechanical vibration, and we have been led to the conclusion that the earth waves produced by the passage of large weights at high speeds affect measuring apparatus far more seriously than the noisy street traffic that rattles the windows of a house. It is impossible, therefore, to view without alarm the proposition to construct a subway for heavy tramcars within a few yards of the two important physical laboratories belonging to the Royal College of Science and the City Guilds Central Institution, both of which are used by considerable numbers of students; and our alarm is turned into dismay when we learn that the Bill which Parliament is to be asked to sanction proposes to grant powers to the new company to propel their trains electrically. For every elementary student knows that he must never walk about near even rough galvanometers, electrometers, and other apparatus used in connection with the study of those all-important practical subjects, electricity and magnetism, if either his keys, or his knife, or his watch be in his pocket. Even a tyro in the subject will not then be surprised at our observations showing that powerful electromoters on electrically-propelled tramcars constantly passing within a few yards of a physical laboratory would make even rough electrical measurements impossible. Now that the nation is devoting so much attention to the spread of technical education, now that Parliament has sanctioned the spending throughout Great Britain of considerable sums for technical instruction, is it possible that the people will allow the Central Institution of the City Guilds Institute, a building that has cost £100,000 to build and equip, and which is the centre of English technical education, to be practically ruined as regards one whole branch of instruction which is participated in by practically every single student of that college ?"

The Engineer and His Workmen.—On Wednesday evening, Mr. Robert Capper read a paper with this title before the Civil and Mechanical Engineers' Society, in the course of which he said: "The associations of workmen in trade unions at the present day were described as aggressive, defensive, and provident. Until quite lately he was under the impression that a vast majority of workmen were members of such bodies, but from the Blue-book returns, which were admittedly incomplete, this did not appear to be the fact. While the wage-earning part of the population was between five and six millions, the number of unionists did not exceed 600,000 at most. Though the total number of trade unions was over 300, a large majority of them had but a small membership, some being as low as 10. Many neither kept nor published complete records of their transactions; others objected entirely to supplying information as to their affairs, and well they might, inasmuch as one trade union of 56,000 members and an income of £28,000 had quite recently boasted that it had spent, and was spending, 22 per cent. more than it received. There was a generally prevailing idea that trade union funds were spent chiefly in fighting employers, and he had been astonished to find it officially stated that out of 39 of the principal trade union societies, with a total of 274,727 members, an aggregate of £33,729 had been expended in dispute-pay—a general average of 2s. 4½d. per member, which was a very small proportion indeed. The labour correspondent of the Board of Trade avowedly sympathised with the aims of trade unions. For this he could not be blamed from an employer's point of view, because the employers, as a class, had never given the workmen a choice of unions. Although trade unionism had made heavy drains upon the workman's pocket, it had advanced rapidly during the last year or two, and it was a question whether the time had not come for the engineer, as an employer, to brace himself up and offer the workman a choice between trade unions, a trade union with both engineers and workmen sitting at the same table or leave the workmen the prey of a paralysing influence. The majority of the strikes that had recently taken place were without any sort of justification, while agreements and stamps had been regarded as waste paper. There was, however, a large amount of common-sense among the better class of workmen, as could be seen from the resistance offered to the advanced aggressive school at congress. The remedies proposed in the matter were conciliation boards, profit-sharing schemes, and union of employers and workmen. Neither in London nor elsewhere was the first system in order, owing to the supineness of the employers."

Telephone in the West of England.—At a public meeting held last week at Exeter to consider the question of extending the trunk telephone line from Newton to Exeter, Mr. Lewis, manager of the Western Counties Company, attended, and described the growth of their system in the district. In 1883 they had 521 subscribers and 250 private wire renters, or 771 in all. In 1887 the number had increased to 2,034, and in 1890 it was 3,587. The number of calls passing through the exchanges in 1885 was 595,000, and as each call received a reply they had a total of 1,190,000 communications. In 1890 there were 3,013,000 calls, or 6,026,000 communications. This would show them what a great assistance in business the telephone was. He was sorry to see the slow growth of the system in Exeter, but he attributed this to the fact that the city was isolated and that the telephone was not of the same value there as in such towns as Bristol, Worcester, and Birmingham. In Exeter they had only 41 subscribers, 25 of whom only were paying subscribers. There were free communications with the police station, fire-engine station, and other places. Strange to say, the hospital had not accepted their offer to connect them with the exchange. He did not know the reason, but he hoped before long the governors would change their minds. Mr. Lewis then went on to explain the system of trunk lines, and said at present there was an important break in the system—namely, between Weston-super-Mare and Newton. If the line was only completed, it would place them in communication with 3,000 subscribers; if it was only constructed between Newton Abbot and Exeter, it would connect them with 500 traders—300 at Plymouth, 200 at Torquay, and others at the smaller towns. The cost of making the short line would be about £1,200, and the longer one about £3,700. If the company saw a prospect of receiving any reasonable support at Exeter, Bridgwater, Taunton, and Weston-super-Mare, they would be prepared to undertake this outlay; but their company was one trading for a profit, and of course they had to consider the shareholders' interests as well as those of the customers. If the work was only carried out Exeter would then be in communication with Worcester, Birmingham, Liverpool, and Manchester. It was said sometimes that the annual rental of £10 was heavy, but it was hoped if the royalties could only be abolished that the charge might be reduced. Mr Houlditch asked if the outcome of the meeting could not be practical. Let them secure 25 additional subscribers, and then Mr. Lewis could go to Taunton and secure another 25. In that way they would soon be placed in communication with towns in the North and with London. Mr. Lewis said if he could get 55 additional subscribers in Exeter, Taunton, and Bridgwater, he would recommend the directors to expend the £5,000 in constructing the longer trunk line. He thought they might in 18 months' time have connection with London. After further discussion and explanations, the proceedings were brought to a close, the Mayor and other gentlemen offering to become subscribers.

UNDERGROUND MAINS.—II.

THE CROMPTON SYSTEM.

(Concluded from page 74.)

The culverts when going under roadways have to be made of extra strength to carry the heaviest traffic without fear of the covers breaking or the side walls crushing in. Certain regulations have been issued by the London County Council, and the designs of culverts and covers given are constructed fully to comply with these requirements. The trenches in these cases are about 4ft. deep. The illustrations show cross sections and longitudinal sections of a 2ft. culvert under roadway. The smaller culverts are of similar construction, the only difference being in the width. The culverts have a solid cement bottom, and the walls are of 9in. brickwork set in cement and with an inside coating of cement to prevent any percolation of moisture.

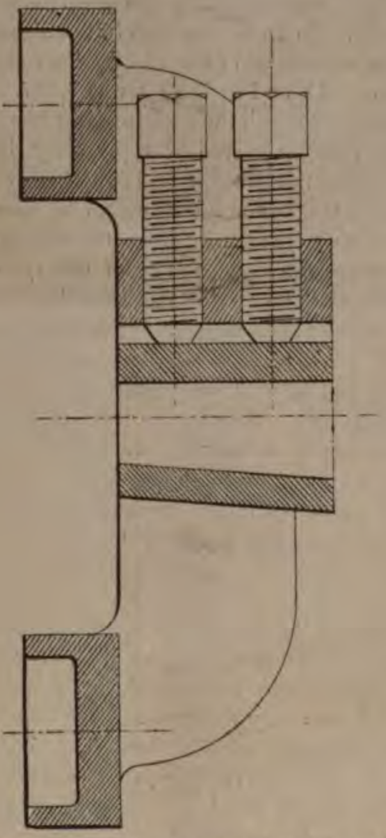

FIG. 13.—Straining Bridge.—Section, showing wedge-shaped opening for gripping copper strips.

They are also sometimes constructed entirely of cement 9in. thick. Two methods of covering the culverts are adopted according to judgment. They are either covered in with two thicknesses of 2¼in. York stones; or in some cases with cast-iron covers having ribs on the upper surface and filled in with concrete. Both these methods are shown in the illustrations, Fig. 7 being a longitudinal section of a culvert, half of which is covered with thick York stones, and the other half indicating the culvert as covered with ribbed iron plates and concrete. Fig. 16 is a reproduction from a photograph of the work of trenching.

The covers to the boxes under the roadway have, of course, to be adapted to the nature of the rest of the roadway surface. Both the insulating and straining boxes are dealt with in the same way. The covers are made of a cast-iron frame, hollow on the upper side, fitting into the boxes and easily removable for inspection. The hollows in the upper surface are filled in with concrete, cement, asphalte, or other material, to match both the colour and the rate of wear of the material of which the roadway itself is constructed. The joints of these covers are made water-tight, and at the same time noiseless, so as not to vibrate under the traffic, by inserting a serving of tarred rope in the framework of the box before the cover is put on. Where wood pavement is in use, the cover is made with ribbed openings of the necessary size to match the rest of the pavement, and hard wood blocks are cemented in, as shown in the illustration, Fig. 9. The arrangements for connecting a culvert under a roadway with that under the pavement are seen in Fig. 8.

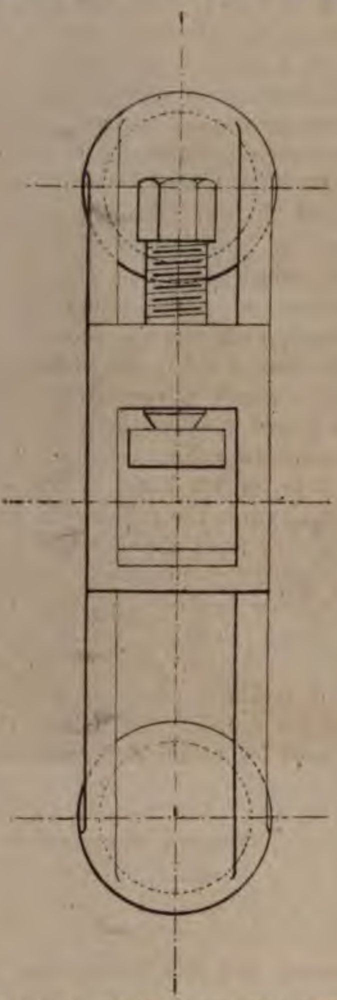

FIG. 14.—Straining Piece.—End view.

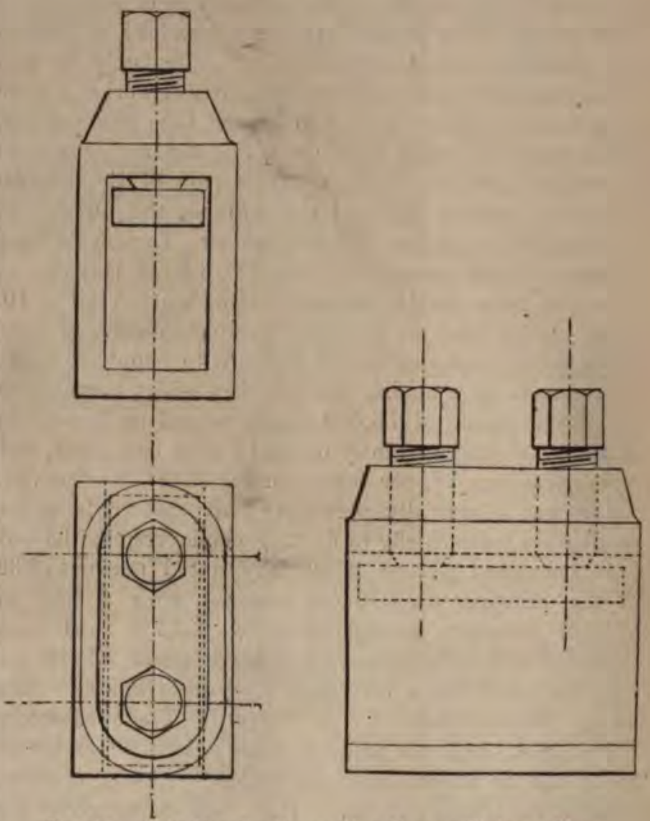

FIG. 15.—Grip Box for Connecting Copper Strips.—Plan, end, and side view.

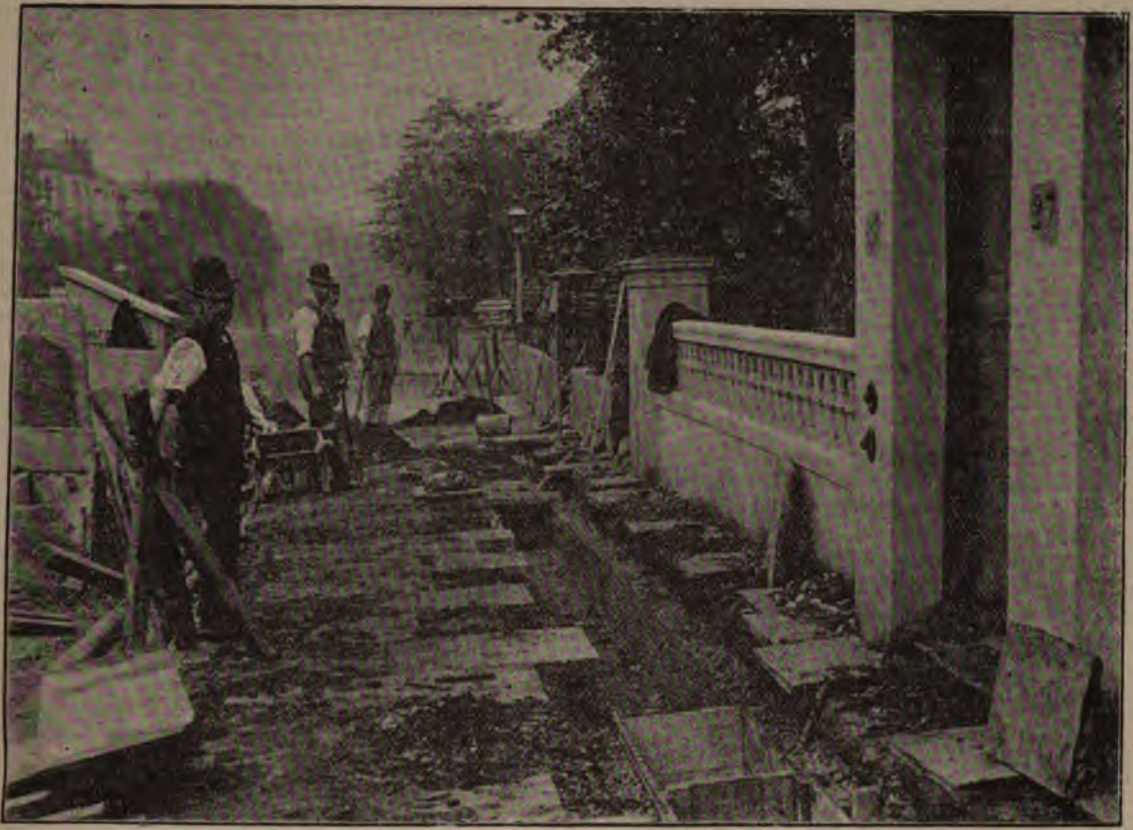

FIG. 16.—Trenching and Cementing.

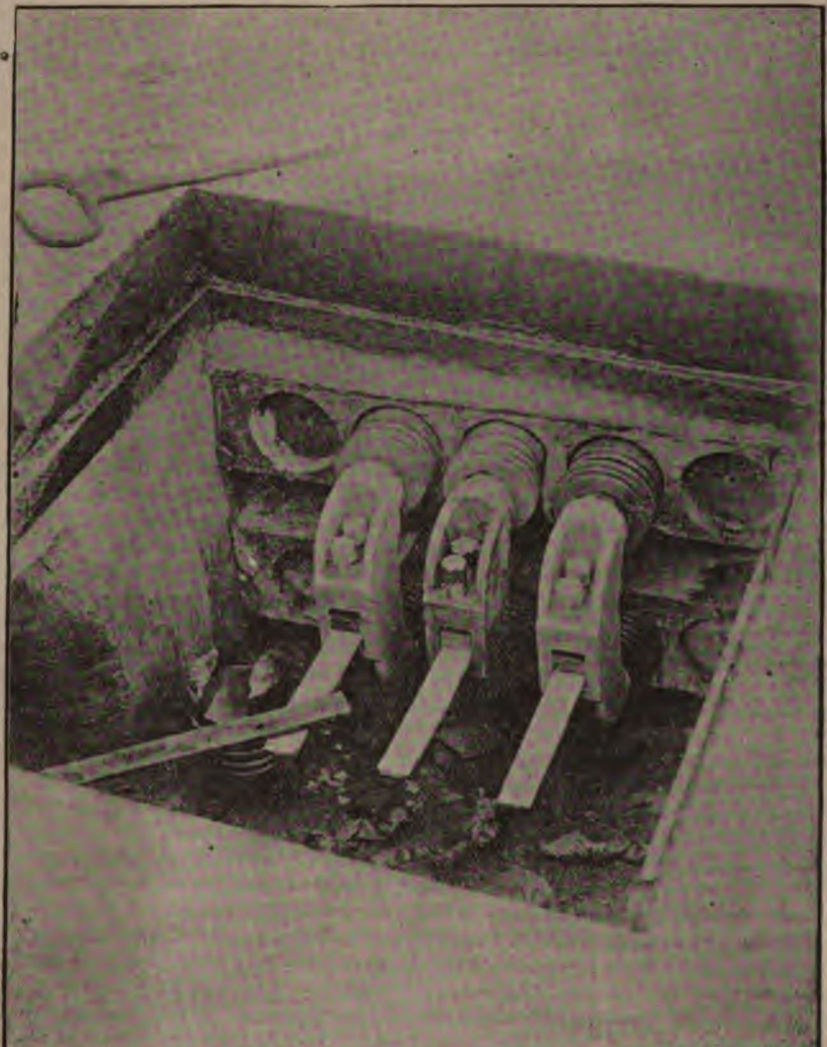

FIG. 17.—Straining the Cable.

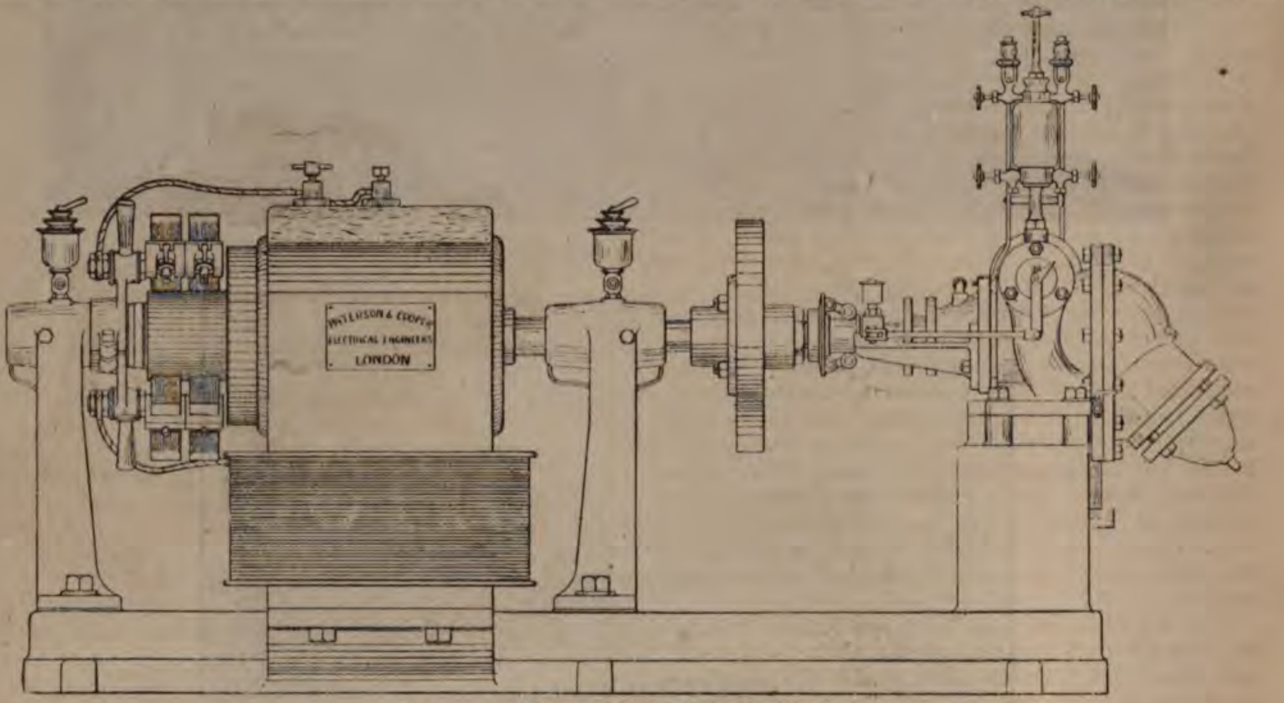
It sometimes happens that the space under the footway is so small that culverts cannot be built. In such cases heavily-insulated cables drawn into pipes are used for the distance required, each cable having its own separate pipe.

The ends of these pipes are brought into insulator or straining boxes (Fig. 17) of the same form as those used for the culverts, and the cable is screwed tightly to the copper strips in the manner shown. Similar arrangements are adopted for connecting the house mains to the three-wire mains. They are led to the nearest insulating box, and are connected respectively to the inner main and one of the outer mains. If it is ever necessary to alter the balance of the current in the two halves of the three-wire mains, it is a matter of a few minutes' work to lift the cover, unscrew one end of the house main, and screw it upon the opposite outer main strip.

PATERSON AND COOPER'S SHIP LIGHTING PLANT.

The accompanying illustration shows a Phœnix dynamo driven direct by a Tower engine. This combination has been designed by Messrs. Paterson and Cooper for ship lighting. The dynamo gives 92 amperes at a pressure of 100 volts, running at 550 revolutions per minute. Four combinations of this kind have recently been supplied to a firm of shipbuilders to be placed in duplicate on two large steamships, the specification limiting the rise of temperature in continuous running to 25deg. C. or 45deg. F. above the surrounding atmosphere. The machine in reality runs without heating to anything like this extent, and will usually give an output of 25 per cent. above the normal without any undue heating or sparking.



Paterson and Cooper's Ship Lighting Plant.

THE KEYS ELECTRIC COMPANY.

Hardly a week passes but we insist to our readers upon the importance of the speedy introduction of electric motors to the better notice of the general public in our large towns. We insist for two good reasons: that the enormous demand for electric power which inevitably must spring up, in houses and in smaller workshops, will itself be a boon to private householders and to small manufacturers when the advantages of the use of electric energy are fully known and appreciated; and we insist again from the point of view of the supply companies, who not only have a further large field for supply of current to be tapped, but that this supply tends constantly to fill up the idle hours of the day, to swell out the load diagram, and give that result dear to electrical engineers, an economical, because constant, generation of electricity.

The first necessity, we suppose, for this wide appreciation of the advantages of the electric motor is a permanent exhibition, where the household apparatus, such as knife-cleaners, sewing machines, and washing machines, and all the other minor mechanical aids to civilisation's progress, might be beholden by whoever will in actual operation at their very doors, not to speak of the really more important examples of turning lathes, churns, and other manufacturing appliances driven electrically.

Even at the public electrical exhibitions these utilities, though occasionally present in odd corners, have been presented by English manufacturers in no striking *ensemble*, no telling adaptation appealing at once to the alert manager and the good housewife. These things, we say, ought to be done, for public opinion must be trained to the advantages of the clean, easy, and silent electric motor.

Well, as no English company and firm are taking up the matter in the manner it should be done, the Germans are going to show us the way. We confess we should better have liked to see the initiative on such an important point taken by English companies for English manufactures, but better have it done by competitors than not done at all, and certainly the lead is being taken by a poweful firm, whose reputation on the Continent is almost second to none, and whose products we have in England had as yet no opportunity of seeing. We allude to the Allgemeine Elektricitäts Gesellschaft (General Electrical Company of Berlin), the outcome of the old German Edison Company.

A company has been formed in England under the name of the Keys Electric Company, Limited (having bought up a small private company of that name), who have taken spacious and imposing premises in the centre of London at 122-124, Charing-cross-road, and opened therein a permanent exhibition of electric light in action, electroliers, instruments, dynamos, and motors, the latter both for heavy transmission of power and also embodying many useful applications of small electric motors to ordinary household work.

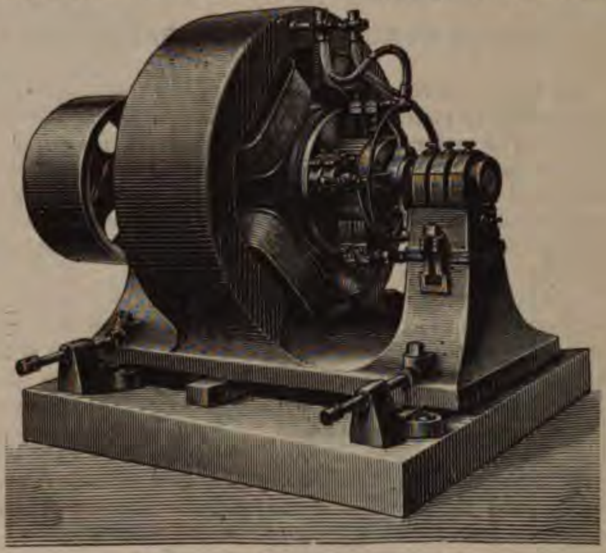
The company act as sole agents for the introduction and sale of the numerous specialities of the Allgemeine Elektricitäts Gesellschaft of Berlin, and is practically under the same direction. Mr. A. Reckenzaun is consulting engineer to the new company.

A few words as to the position and scope of the Allgemeine Elektricitäts Gesellschaft may not be out of place here, for, although their work and standing is well enough known to some of the electrical profession, to many others this powerful continental company is little more than a name. The company have now a capital of 20,000,000 marks, that is, of £1,000,000 sterling, of which their former capital of 16,000,000 marks has lately been increased by 4,000,000 marks, at 80 per cent. premium, the 1,000 mark shares offered selling for 1,800 marks, and the new issue of four million being thus sold for 6½ million marks. They have paid a dividend of 10 per cent. during the last two years, and in addition to this have written off more than five million marks (£250,000)—their patent account, on which they have spent over one million marks, now standing in their books at one shilling. This is a result which we suppose no other electrical company can show in its balance-sheet, and is in itself a marvellous commentary on the activity and enterprise of the Berlin company. They have a large machine factory in the Ackerstrasse employing 1,200 hands, a lamp factory in the Schlegelstrasse, of which the output is 4,000 to 5,000 glow lamps a day. The Central Station Company of Berlin (Berliner Elektricitäts Werke) is a branch of the same concern, under the same directors with separate capital, having now nearly 15 million marks (£750,000) invested in central station plant and buildings. There are four large central stations in active operation, having all their systems of underground mains connected together in a manner to be able to help each other in supply when necessary, the total capacity at present being equal to 150,000 16-c.p. lamps simultaneously, and additions to the central station capacity of 100,000 lamps are in course of construction. Besides this, the Allgemeine Elektricitäts Gesellschaft is interested in many separate electrical enterprises. Of these the Neuhausen Aluminium factory is perhaps the most important, having a capital of very nearly 10 million marks. The Tudor Accumulator Company is another, having four million marks invested. In the Madrid central station they are the principal shareholders, holding half the shares, and are the constructors to the station; and there are various other electrical enterprises in which they are equally interested. It is this company for whom the Keys Electric Company are acting as English branch for the supply and exhibition of electroliers, switches, switchboards, instruments, and dynamos; and with a working exhibition for pushing the use of motors for domestic and industrial purposes. It may be mentioned that the large engineering works of the Allgemeine Company in the Ackerstrasse are run entirely by electric motors, every machine—planing, boring machines, lathes, and other machine tools—being fitted each with their own separate motor, and the cost of power is found no higher than by steam, while the convenience is far greater. As an illustration of the extended and economical use of the electric motor these works afford in themselves a fine example.

The premises taken by the Keys Electric Company in the new Charing-cross-road, at the Oxford-street end, are very spacious and commanding, giving two long floors for showroom purposes, besides upper floors and offices. The electrolier showroom is upon the first floor, and is likely to be found one of the finest shows of fittings in London. It is filled with electroliers of very varied and ornate type, mostly made by the manufacturing company in Berlin, but showing also many specimens of ornamental fittings of the best makers in France and with others of English manufacture. In this showroom there are in all a total of 350 lamps, wired ready for lighting, on 100 different circuits, each of which can be separately switched on by means of four distributing switchboards. Very many handsome and striking pendants are to be found amongst this selection.

On the ground floor are a large number of dynamos and motors. The dynamos range from 2½ unit to 25 unit, of double-pole type with solid yoke. A special feature of the dynamos is the short-circuiting of the magnetic pole-pieces, an arrangement adopted to prevent sparking at the brushes. A ring of soft iron encircles the armature, being inserted between the bored-out pole-pieces, so as to connect them across by the thickness of its ring. At the top and bottom this ring is slotted out in oblong holes, or thinned down, and drilled out in a series of small circular holes so as to leave only a slight sectional area of soft iron, absolutely short-circuiting the poles. The electrical efficiency of the machines is given at 95 per cent. The motors are of a similar type, with an outside circular yoke, having several inside pole-pieces and magnet windings. Considerable attention has been given to the construction of these motors to render them effective and efficient, and it is this type of motor which is employed as mentioned to drive the works, and in many installations for the transmission of power carried out on the Continent.

On the same floor is the permanent exhibition of electric motors in working order, to which we have alluded. Small ⅛th h.p. motors of Crocker-Wheeler type are used in some cases, and motors of their own manufacture are being fitted up shortly for similar as well as for heavier work. We see one of Pfeil and Co.'s lathes steadily whizzing around on the turning of a small switch, the motor being arranged alongside on the floor, and driving by means of a tiny line of countershafting. In another corner is a Blackman fan, used to ventilate the accumulator-room below—a very useful application. Then is encountered a whole set of domestic mechanical contrivances, all merrily rotating by the aid of the little motors. There is one of Bradford's well-known knife polishers, with several other of the same maker's aids to quick work, a boot cleaner, with its various brushes—dirt brush, blacking brush, and polisher—sticking grimly out ready for the family's morning supply of boots. Further along is a washing machine, with its uncouth wooden box for dirty linen and its screwed down lid; and alongside, a wringing machine, with its wooden rollers, grievously suggestive of wet sheets and weary arms—henceforth mildly working by the turning of the electric button. There is a churn, there are sewing machines—but why go on? There is just exactly what the advanced housewife of the day—at whose house the electric light has been turned on—wants to complete her happiness and her belief in the successes of science. And all these machines are made to connect to the 100 or 110 volt circuit, and the motor takes ·6 of an ampere—that is, almost exactly the equivalent of one incandescent lamp. A considerable demand is springing up for sewing machines, and one of the Keys electric sewing machines was being packed for use on the station circuit in Madrid.



Allgemeine Company's G Dynamo.

From the ground floor we can descend by an electric lift—or, rather, will be able to descend, for the installation of the lift is hardly complete. In the basement is the engine-room, a very neat and comprehensive installation of considerable output. There are two gas engines driving two of the company's dynamos. A high-speed Crossley gas engine, giving 15 electrical h.p., drives one of the old type Edison machines, 100 amperes and 110 volts, of the type made by the late German Edison Company, and a Griffin gas engine, giving 8 h.p., drives one of the Allgemeine Company's newer type dynamos. In a side room is a set of E.P.S. 31L accumulators. The switchboard is of the Allgemeine Company's make, fitted with Dolivo ammeters (also made by them), which are already known in this country. The switchboard has two ammeters and a voltmeter, with main and regulating switches fitted with spring-snap action, and an automatic cut-out of their own type for use when charging the accumulators. An Aron meter is used to measure the current supplied. This is a meter much used by the company, although they will shortly, we understand, probably adopt the new and simple type of electric meter invented by Mr. Reckenzaun.

Going again to the ground floor, there are arc lamps and many instruments to be seen. The arc lighting is arranged on the indirect system, by which the lamp globe is covered in below by an opaque shade, and the light reflected upwards upon the ceiling, giving a well-dispersed illumination. A new type of arc lamp will shortly be on view here designed by H. Pieper, the Belgian electrician, being extremely simple in its action and without clockwork, dependent simply on the differential action of the two polarities of the current. Besides the Dolivo volt and ammeters already mentioned, the Keys Electric Company have numerous scientific measuring instruments made by Dr. Edelmann, of Munich (the German Elliott Bros.), resistances, galvanometers reflecting and tangent, testing batteries, calorimeters, etc. One water resistance is interesting, being for the heavy current of 1,000 amperes, with extremely heavy contacts and circulating water baths. There are also quick-break switchboards of the Allgemeine Company's type, shunt resistances for dynamos or for arc lamps, Edison and other fuses. An automatic potential regulator by Cuenod, Sautter, and Co., of Geneva, worked by means of magnetically governed coned double friction wheels is for automatically regulating the E.M.F. of dynamos for lighting. Numerous small motors are quite the feature of the place, together with a further display of handsome pendants in the showroom windows.

OULTON-EDMONDSON ELECTRIC METER.

We have received the description of the Oulton-Edmondson electricity meter, of which an illustration is herewith given. The meter is upon the principle of measurement by the retardation of two similar pendulums, one being influenced by the electric current. The meter is both for continuous and alternating currents, and embodies some novel arrangements for the simple and exact realisation of its objects.

In a few words, the meter consists of clockwork with twisting pendulums of the kind familiar to those who have seen the "400-day clock." The left-hand pendulum is connected with two swinging solenoids which affect the speed of this balance as compared with the other. In the figure the two heavy circular balances are seen hanging by long thin strips, the "torsion spring," with the clockwork and dials between them. Below are the two swinging coils, and around the lower one the main conductors of strip copper are seen. Below these are two mercury cups, and to the right the negative and positive main terminals. In the upper corner is a fixed resistance coil, and above this the terminal for the high-resistance circuit.

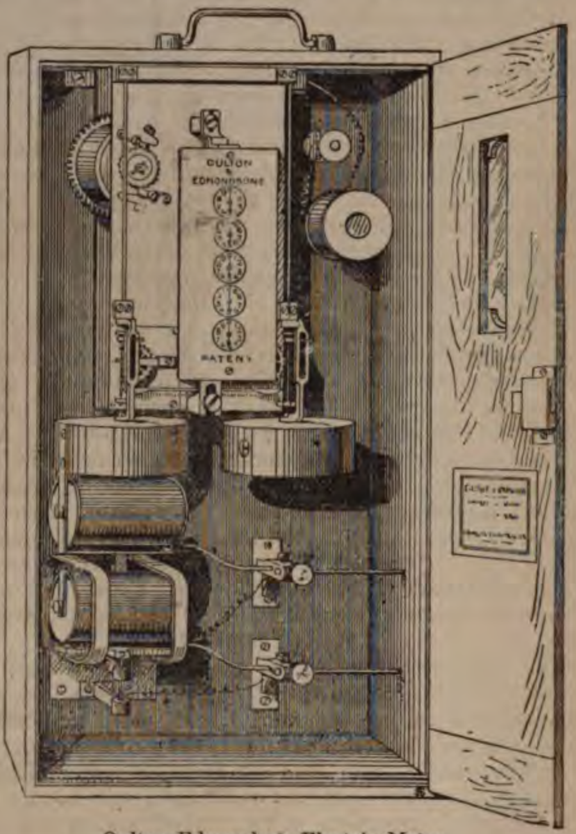
This wattmeter, therefore, consists of a set of clockwork with two torsion balances, which keep identical time except when current is being used. When a current passes through the main conductor it quickens the speed of one of the balances, and the difference in speed, registered on the dials in Board of Trade units, is a measure of the current consumed. A difference of 10 beats an hour equals one Board of Trade unit, and the measurement is proportional to the current throughout the whole range for which each instrument is constructed.

The clockwork is of first-class quality, with "high numbered" pinions. Both balances are driven by one main spring, the force of which is equally divided between them by a novel differential gear, and their synchronism is therefore practically perfect.

The electrical arrangements consist of two compound-wound solenoids, astatically attached to one of the balances, and swinging, the one above, the other within, the coils of the main conductor, and influenced by the current to be measured.

The principal winding of the swinging solenoids consists of fine wire, connected with a fixed resistance coil, by which the instrument is calibrated, and coupled across the supply terminals. In a 100 ampere-meter these high-resistance or volt coils consume about ·007 ampere on a circuit of 100 volts. By themselves, however, they would not give proportional readings, for the reason that in pendulums and chronometric balances, the force required to produce the vibrations is proportional to the square of the number of vibrations in a given time. If, therefore, a = the normal number of vibrations, and b = the number to be added by the current, the force required to produce a will be a^2 and to produce $a+b$ will be $a^2+2\,a\,b+b^2$; the difference $(2\,a\,b+b^2)$ being the force to be exerted by the current under measurement. With the volt coils alone, the force actually exerted would be in the ratio $2\,a\,b+b$ only. Upon each volt coil, therefore, there is wound a "correcting coil," carrying a very small proportion of the current passing into consumption. If correctly calibrated, this small current brings the ratio up to $2\,a\,b+b^2$. This correction is made mathematically perfect, and makes the readings absolutely proportional throughout any range.

In meters in which the influence of the current on a vibrating pendulum or chronometric balance is the basis of measurement, the element of friction is entirely dealt with by the force of the clock, which supplies power exactly in proportion to the speed of vibration. The current under measurement has, therefore, no friction to overcome. Hence such meters register the smallest as accurately as larger currents. The following are the details of the meter:



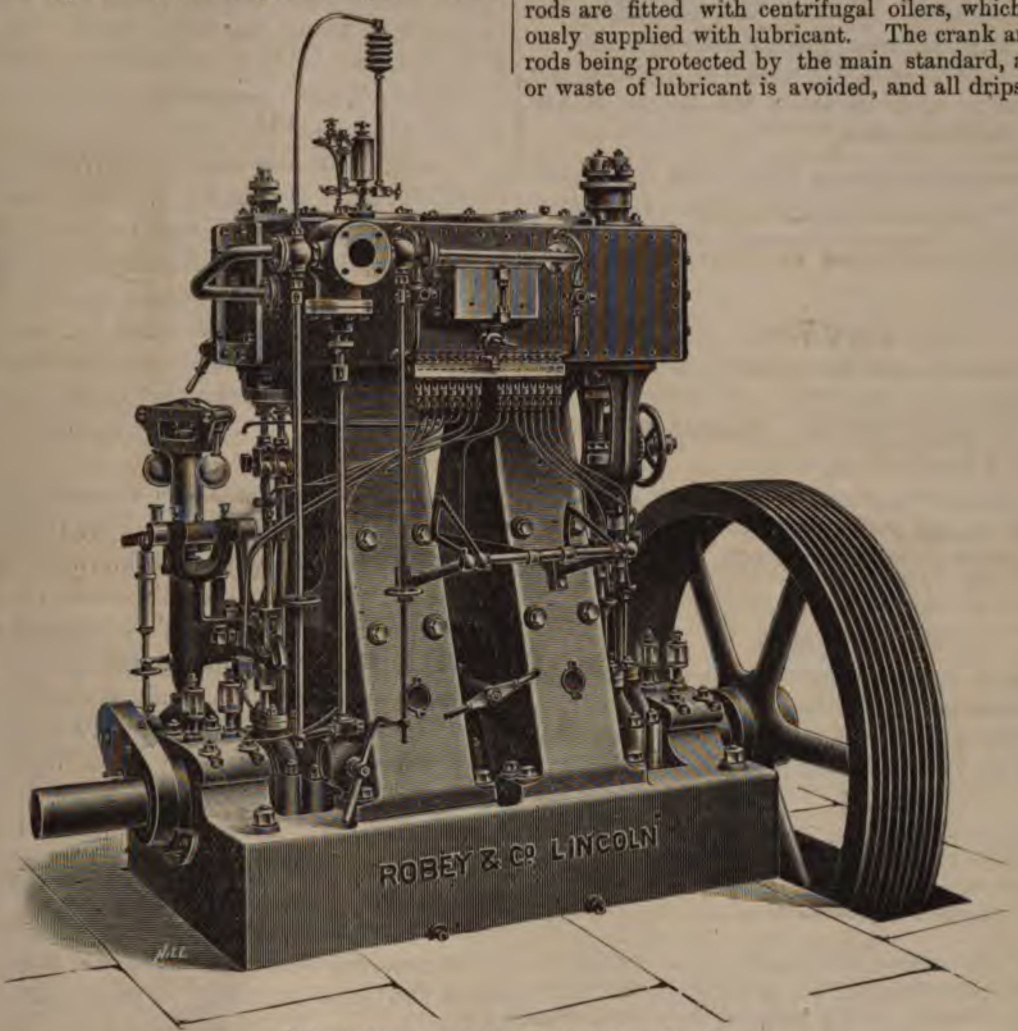
Oulton-Edmondson Electric Meter.

The external dimensions are 19½in. high, 12½in. wide, 6½in. deep. The right-hand balance weighs about 4lb. It contains two "timing screws," which are really small weights, which, when screwed inwards, will quicken and when screwed outwards will retard the speed of the vibrations. The number of vibrations is about 15 per minute. The balance-spring, instead of being coiled as in a watch, is quite straight, acting in torsion, and forms the means of suspending the balance, which thus vibrates practically without friction. The left-hand balance with its solenoids are made of the same weight as the above, so as to vibrate in the same period of time. Although driven by the same mainspring, the two balances are free to move independently.

The current for the volt and correcting coils is conveyed from the positive terminal to the mercury cup, placed concentrically with the left-hand balance, into which a wire upon, and concentric with, the balance projects. After traversing the volt coils it is conveyed up the "torsion spring," and through the fixed resistance coil to a terminal near the top of the case, and thence to the negative main. The current traversing the correcting coils returns through the upper mercury cups to the negative terminal of the instrument. This current is very small, as for one ampere on the 100-volt circuit it has to furnish a magnetic force equal to only $\frac{1}{1800}$ of that furnished by the volt coils. As, however, the turns in the correcting coils are much fewer than those in the volt coils, the actual current in the former may be (for one ampere) somewhat greater than in the latter, and it increases in proportion to the current consumed.

The denominator of the fraction $\frac{1}{1800}$ is the $2\,a\,b$ of the difference $2\,a\,b + b^2$ mentioned above, when the balances normally vibrate 900 per hour.

The advantages claimed for the Oulton-Edmondson meters, which are made by Mr. Joseph Edmondson, 36, Sunbridge-road, Bradford, are that their synchronism is much more accurate than has been attained in previous meters acting on the same principle; they will go for three months without rewinding, even when worked up to their full capacity; they will measure any current however small; they give proportional readings over a longer range than any other mechanical meter extant; the electrical energy consumed is less than in any other existing watt-meter; the dials register the consumption in plain Board of Trade units; and, finally, that there are no "make and break" contacts.



Robey's Compound Electric Lighting Engine.

ROBEY'S COMPOUND ELECTRIC LIGHTING ENGINE.

Messrs. Robey and Co., of Lincoln, have paid just attention to the construction of engines for electric lighting purposes, and have designed a series of engines especially for electric light installations. These engines vary in power from 40 to 200 i.h.p. The engine, as illustrated, has high-pressure cylinders 11in. diameter, low-pressure cylinders 18in. diameter by 12in. stroke, and makes 200 revolutions per minute, though it can be worked up to 250 revolutions. The crankshaft is 6in. diameter, and has three bearings, with a total length of 32in. All the working parts have very large wearing surfaces, and the engine throughout is of most massive build. Every part is carefully balanced, and the right provision made in the set of the valves, so that the engine can be run at the high speed of 250 revolutions per minute with ease and safety. There is a total absence of vibration or shock. All the working parts are well lubricated from a central oil-box, which is fitted with a gauge showing its contents, and each separate point to be oiled has an independent adjustment with a visible drop feed.

The engine is governed automatically by link expansion gear controlled by a powerful Richardson governor, and not more than 2 per cent. variation in the number of revolutions is made between all load on and the engine running light, while with ordinary changes of load the variation is imperceptible. The governor is driven direct from the shaft through machine-cut wheels which are enclosed in a casing. The weight of valve rods is compensated by means of steam plungers, so that the whole motion is in complete balance. The governor is also fitted with an extra adjustment, by means of which the speed can be varied while the engine is running, and set at any required number of revolutions. The large ends of the connecting rods are fitted with centrifugal oilers, which are continuously supplied with lubricant. The crank and connecting rods being protected by the main standard, any splashing or waste of lubricant is avoided, and all drips are collected in suitable wells in the base-plate, from which all the oil can be removed by passages and cocks arranged for the purpose. The lower part of the columns on the front side is arranged to be removed when it is required to examine the crank-pin, or to take out the crank, and this can be quickly and easily done without disturbing any other part of the engine. All the levers and handles are brought conveniently together in front of engine, so that the starting valve, intermediate receiver, drain cocks, and governor adjustment can all be attended to from one position. The engine may be used to drive a dynamo direct, or with belts or ropes. The engine the particulars of which have been given has been made for the Newcastle-on-Tyne Electric Supply Company, and drives a 37-unit Mordey Victoria alternator, which developes 70 to 75 h.p.

This company has in its Newcastle station three other coupled compound engines of Messrs. Robey and Co.'s make, like the one illustrated, each of 200 h.p., and which are used during the evening. The smaller one is used for day lighting, and to work during the day and night in conjunction with one or more of the larger engines.

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VI. inclusive, new series, of "The Electrical Engineer" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

We may occasionally follow the lead of our American Contemporaries, especially when they point out a serviceable way. They are not backward in asking their friends to do all they can for the welfare of the paper. We ask our friends to remember us. No Paper that we know ever refuses Subscribers or Advertisers. Nor do we; in fact, we invite them, believing that they will get full value for their money.

Specimen copies of the paper will be sent on request.

1891.

In telephony there is little of a definite character to relate. In London the system is unsatisfactory. A portion of the controlling patents has lapsed, and within another six months or so, another monoply badly managed in the metropolis of the world will have passed away. It must be conceded that the existing management has not had time to retrieve the fortunes of what might have been the most gigantic business concern of modern times outside the Government. We have usually selected the Western Counties and South Wales Telephone Company as an example of how energy and common sense will send business along, and the figures on page 93 will indicate that during the past year there has been no lack of enterprise. The opening of trunk lines, the giving of concessions to subscribers, are all steps which add to prestige and to income.

Passing from the work of private companies to that of the Government, we have the most important telephonic work now in hand that has ever been undertaken in this country. We refer to the telephonic connection between London and Paris, which it is hoped will be completed some time next month. It will be time enough to discuss the whole question when the work is complete, meanwhile the proceedings are being watched with great interest.

"Of the making of books there is no end," and the remainder of the verse is by this time of the world's history pretty well known. Most of the people one meets are not disposed to trouble themselves much about Solomon's wisdom, for, say they, the study of books means knowledge, and knowledge means money. We are inclined to think that however illnaturedly some books may be spoken of, no book ever issued from the press but it had good points. There is no doubt, however, but that in the majority of cases the good points are hidden, while the bad points are like thorns, making themselves felt. It has been said that a man's character is known by the company he keeps, and that is so, yet a great deal more than character can be told if we know the books he reads. Fortunately for the few, the major part of those engaged in industrial occupations are not readers, either of technical books or technical papers. The few who want to know get to know, and gradually rise above the ruck of their fellows. They must, however, be workers as well as readers, otherwise their ultimate position is far below what it might be. Again, the omnivorous reader is better than the man wedded to one book or one paper. Dean Cust put this very pithily and pointedly once to us. His conclusion was that the man who read and swore by one particular paper was not far removed from absolute ignorance, taking all that was told him by this one paper as gospel, never asking if there was another side to the question, and never thinking about it at all. What was said in his particular paper was said, and was right, and that ended all discussion. Most men find it exceedingly difficult to "think"; hence they choose a hero whom they

THE WESTERN COUNTIES AND SOUTH WALES TELEPHONE COMPANY, LIMITED.

The company was formed in December, 1884, for the purchase, working, and extension of existing telephonic exchanges, and establishing others, as well as for the supply of telephones to the general public. It has now in operation telephonic exchanges in the following places—viz. :

Bristol.
Clifton.
Bath.
Gloucester.
Cheltenham.

FREE USE FOR COMPANY'S SUBSCRIBERS OF CALL ROOMS IN ALL TOWNS IN THIS COMPANY'S DISTRICT.

In October last the directors arranged to issue three free call room passes to each subscriber applying for them in respect of each exchange connection, and they have now decided to extend the benefit so as to enable a subscriber or his representative to use the pass for local calls in any town in which he may happen to be, and they do not doubt this convenience will be appreciated by the subscribers. This new facility came into operation on January 1st, 1891.

---

worship. What he says they say; what he does they ape. Just so with technical books and papers. If Smith's hero says sea-water is green, Smith says it is green; so Jones says it is "blue" because his hero says it is blue. Neither Smith nor Jones trouble to decide for themselves. Authority—authority—authority is the cry, and he who resents authorities crammed down his throat is anathema. We are led to indulge in remarks of this kind by a thought of the success of Mr. F. C. Webb's little book issued in 1862, as compared with the success of books a million times inferior during the past year. Then it was more difficult to sell one copy than to sell a thousand now. Part of this difference is due to the conditions existing, but not all. No man living or dead had, previous to Mr. Webb's work, so ably discussed the true principles upon which certain electrical calculations must be based. Years after these principles had hardly permeated among the class whose ranks are supposed to stand in the forefront of science. It took long years before the labours of Cavendish and Green were recognised, and we desire a less lengthy period to elapse before giving Mr. Webb that credit to which he is justly entitled. "The earth a reservoir" was generally held till Webb demonstrated the utter rottenness of the doctrine and proved his point up to the hilt.

A number of books have been issued within the past year, which, for one reason or another, have not yet received the notice they merit in our columns. We shall, therefore, refer briefly to the most important of these books, some of which we believe ought to be in the hands of every member of the industry.

"ELECTRIC TRANSMISSION OF ENERGY," by G. Kapp, C.E. (Whittaker and Co.).—This book has now reached a third edition, and although the new edition does not differ materially from the previous one, care has been taken to revise and incorporate when necessary. Up to page 124, for example, the editions are verbally the same, then come transpositions, additions, and elisions; then again textual similarity, and so on. When the first edition of this book was published we expressed our opinion as to its value—time has not altered our opinion. Mr. Kapp knows that on certain electrical questions we differ; yet, while differing, it must be acknowledged that no other man has done more to enlighten his fellow-men upon what may be termed the technics of his profession. His papers before the Institution of Civil Engineers, before the Institution of Electrical Engineers, have been pre-eminently practical, while this book provided for a new field—one that must be of great magnitude, and one that was and is little understood. There is one suggestion we might venture to make.

A number of suggestions, emanating from others than the author, are given. Some of these are never likely to come into practical use. A number of dynamos are described and illustrated, and are evidently given a place because the author desires not even to seem to select one maker before another. Unless there is some really distinctive feature in each dynamo to require a description, there is no need to pile up the number described. In the near future we are likely to accumulate a mass of information which, when duly digested, will require all the space that Mr. Kapp can spare in future editions. The only way, so far as we can see, in which the space can be obtained without adding materially to the bulk of the book, is to leave out unworkable suggestions, and the repetition of descriptions. Mr. Kapp, no doubt—in fact, he must have done—noticed the somewhat hazy notions existing among engineers cropping up during the discussion at the Institution of Civil Engineers as to the efficiency of an electric system with and without a motor in the system, and these hazy notions will not be cleared up till further information is given to those who make the mistakes. Mr. Kapp's book goes a long way, and gives a large amount of very valuable information; but we should like to see incorporated in the book a full account of 12 months' working on the City and Southwark Railway. Of course we must wait for such statistics, but they will be forthcoming for future editions. Meanwhile, as we have said, this edition has been corrected up to date.

"ELECTRIC LIGHT INSTALLATIONS AND THE MANAGEMENT OF ACCUMULATORS," by Sir D. Salomons, Bart.,(Whittaker and Co.), is another new edition—the sixth. Fortunately it is not necessary to criticise the contents of new editions. Good technical books are revised, and editions, like the brook, say "Men may come and men may go, but we go on for ever." This work of Sir D. Salomons is, or should be, a standing warning to literary dry-as-dusts. It is not, it does not pretend to be, an ultra-scientific treatise—it is, and it pretends to be, a simple and graphic account of how to go about the work connected with installations. Commencing as a somewhat meagre pamphlet on accumulators, it has grown, edition after edition, to a bulky volume of over four hundred pages. Its great merit is that it can be "understanded of the multitude." We constantly recommend it as the best book from which to get a good working idea of installation work. The enormous value of Sir D. Salomons's remarks arises from the simple fact that they are mostly the result of experience. Most writers of books argue that so and so will take place if so and so be done. Sir D. Salomons uses the apparatus and gives the result. There is hardly a piece of electrical apparatus of repute but Sir D. Salomons has put it to the test. Various dynamos, motors, engines, measuring instruments, switches, etc., have all been tried, and the results given in this work. For years accumulators have been under constant examination; their excellencies and defects have been studied with great care, as the readers will find. Hardly a practical question, so far as isolated installations, and many connected with central installations, but receive notice and explanation. Once more, then, we commend this book to those who wish for general information.

"ELECTRIC LIGHT: ITS PRODUCTION AND USE," by J. W. Urquhart (Crosby Lockwood and Co.), is another book of a general character. It has reached a fourth edition, has been revised and extended. This compilation must have its uses, as is shown by the successive editions. The author has undoubtedly been energetic in collecting a mass of information, though whether he possesses any skill in arranging that information or in selecting the most useful and rejecting the useless is a matter for discussion. It is evident that a certain number of readers want this kind of stuff, which otherwise cannot be said to commend itself as possessing utility. At the present time the reader has to sift the chaff from the wheat, though were this properly done for him the book would be still more valuable.

"ELECTRICAL INFLUENCE MACHINES," by J. Gray, B.Sc. (Whittaker and Co.), is another book appealing to a different class of readers, yet equally deserving attention. In the rapid extension of the use of electromagnetic apparatus, we often lose sight of electrostatic apparatus. There are certain electrical phenomena, however, that can be best studied by the use of influence machines, and certain measuring instruments constructed upon the principles underlying the phenomena obtained. In Mr. Gray the use and description of these machines have an able exponent. We commend to all young readers a careful and even a prolonged study of Chapter II., upon "A Working Hypothesis of the Electric Field." We think the hypothesis exceedingly ingenious, and one that cannot fail to assist the reader to a better understanding of the phenomena involved. It is of the utmost importance that the student should have a concrete rather than an abstract view of the various phenomena, and Mr. Gray's hypothesis enables him to conceive how it is done. Subsequently the author deals with "electrometers," describing and illustrating the well-known instruments of Sir W. Thomson. This brings us to that part of the book which gives it its title, and here we find an historical *résumé* of the development of such machines, followed by a clear and accurate description of a considerable number of the best-known machines, concluding with instructions how to construct such machines as the Wimshurst, and the Holtz and Voss. The book as a whole is a valuable contribution to electrical literature, dealing as it does with a branch of the subject that, so far as we are aware, has never before received separate treatment.

"ELECTRO-MOTORS — HOW MADE AND HOW USED," by S. R. Bottone (Whittaker).—There are thousands of amateurs and students who possess dexterity in the use of tools, and who like to make all manner of apparatus. In after life this handiwork probably gets placed under a glass case, which is given a position and honoured in the house as the work of "father" when he was young. Mr. Bottone caters for these amateur craftsmen. We merely mention the book. It is not one we can deal with seriously. Whatever the economic values of the machine when constructed, we are certain that the knowledge gained in constructing machines such as described in this book, will be of great value to the worker.

"FIRST PRINCIPLES OF ELECTRICAL ENGINEERING," by C. H. W. Biggs (office of *The Electrical Engineer*), is a book, lengthy extracts from which have appeared in our columns. It is intended for beginners whose object is to join the ranks of the industry, and who have no great desire to know about Thales, or ancient Magnesia, or when the Chinese, or anybody else, discovered the compass, who do not believe that passing the South Kensington examinations to be the height of human felicity and the sure road to scientific renown. It would not become us to blame or praise such a work. The author admits it is imperfect, and promises to remedy some of the defects in future editions—if any are wanted.

We have now to refer to specimens of another class of books—books written for the purposes of the South Kensington Science Examinations. There is perhaps no institution that has had greater power for good or for evil in science teaching than South Kensington. In some directions its syllabus is admirable, in others it is bad beyond all conception. Unfortunately, in the particular branch of science in which we are most interested the syllabus is a delusion and a snare, and a student who follows it has far more trouble to unlearn what he is compelled to learn than he has trouble in learning it. The English language is utterly unable to supply words indicative of the harm the South Kensington examinations have done and are doing so far as matters electrical are concerned. They perpetuate a class of books that have nothing to recommend them except they are prepared according to the syllabus. Intelligent thought there is none, inane experiments there are many, and of questions utterly irrelevant to the tendency of modern thought there is an abundance. Many of the books are bald lists of experiments, fit only to be used as a teacher's or lecturer's notes. Viewed from the one standpoint of enabling students to pass a certain examination, many of these works must be commended; viewed as text-books upon scientific subjects, they are worse than useless—they are misleading.

The following two books are among the best of the South Kensington text-books:

"SOUND, LIGHT, AND HEAT" (Elementary Stage), by J. Spencer (Percival and Co.). "MAGNETISM AND ELECTRICITY" (Elementary Stage), by J. Spencer (Percival and Co.).—The author has evidently gauged the height and depth of the examiner's foibles, and no doubt those who go through these books will pass a good examination with credit to themselves and "payment for results" to the teacher. It has not dawned upon the sapient wiseacres at South Kensington that such questions as, What is Electrolysis? or, What are lightning conductors? are incapable of being answered by the most advanced students yet, the pupils in the elementary stages are supposed to know all about it. When shall we record a change for the better?

THE ENGINES FOR KIDDERPORE INSTALLATION.

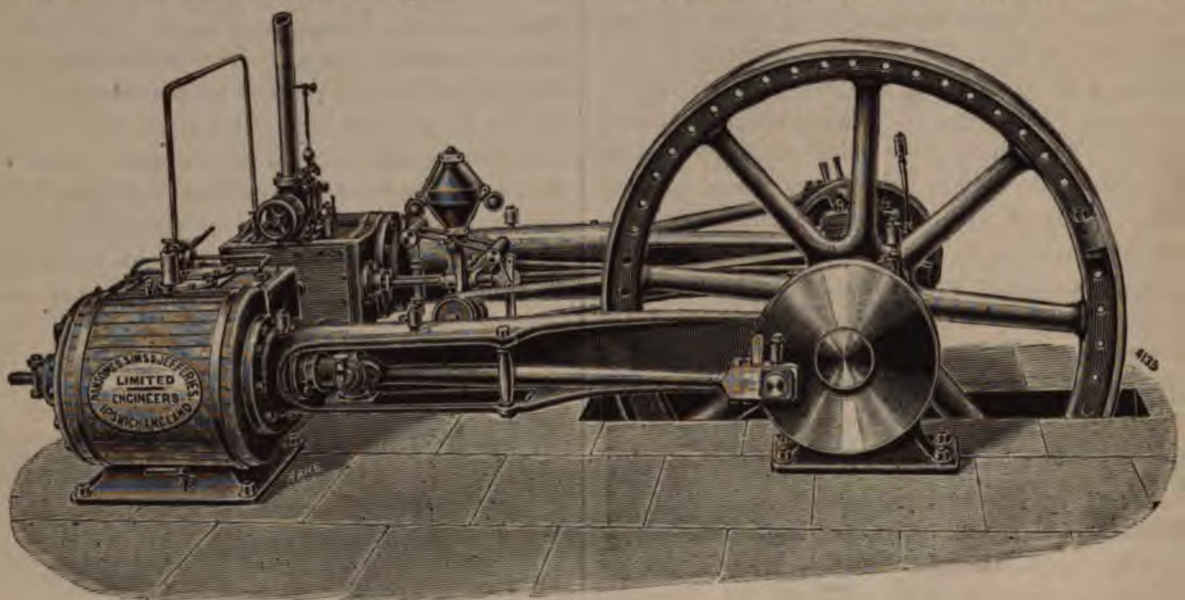
Referring to the general plan and notice of the electric light plant at the Kidderpore Docks, India, which appeared in our issue of the 9th January, we now give, in accordance with our promise, a more detailed description and illustration of Messrs. Ransomes' engines, which furnish the motive power for this installation.

These engines consist of two pairs of the high-pressure long-stroke stationary type, designed and manufactured by Messrs. Ransomes, Sims, and Jefferies.

The engine cylinders are steam jacketed, and also lagged and cased on the outside. The main framing, as will be seen by the drawing, is in one casting, of the hollow girder type, which, while lighter than the ordinary cast-iron foundation plate, is considerably stronger, being in a direct line with the throw or thrust of the engine. The guide-bars are formed by the main frame casting, the guide block being circular and so arranged that the wear may be easily taken up at either top or bottom as required.

A jet condenser of an efficient design is provided to each cylinder, the air pump, which is brass-lined, being worked by an extension of the piston rod through the back cylinder cover. The valves and other parts are well arranged and readily accessible. Special disconnecting valves are supplied so that the engine may be worked with or without a condenser at will.

One of the principal features of the engines is Messrs Ransomes' patent automatic governor expansion gear, which has been used so successfully in connection with electric lighting. In this apparatus an independent gridiron expansion valve, working upon the back of the main slide valve, is operated through a knuckle joint by a link, one end of which is actuated by the cut-off excentric, while the other end is held by a radius rod. The travel of the valve and the point at which it cuts off are governed by the position of the link in relation to the knuckle joint, and this position is varied in accordance with the load on the engine by a powerful and sensitive governor to which the link is connected. By this arrangement the cut-off can be varied between 0 and 70 per cent. of the stroke in proportion to the actual load for the time being on the engine.



Type of Engines at the Kidderpore Installation.

The engines are provided with the necessary feed pumps, and in addition each cylinder is fitted with an improved steam-trap for draining the jacket, and also with a special sight-feed lubricator, the lubrication of the engine being specially arranged for continuous running. The steam for working these engines is to be supplied by two special steel Lancashire boilers, also manufactured by Messrs. Ransomes, Sims, and Jefferies.

INSTITUTION OF CIVIL ENGINEERS.

At the seventh ordinary meeting of the session, on Tuesday, January 13, Sir John Coode, K.C.M.G, president, in the chair, the paper read was on "Auxiliary Engines in connection with the Modern Marine Engine," by Mr. William Henry Allen, A.M.I.C.E.

The paper dealt with the early introduction of auxiliary engines for marine engines, beginning with the year 1870, when the surface condenser was fairly established and the marine engine had assumed the form of the twin compound engine. The author referred to circulating pumps, separate air pumps, fans for forced draught, reversing engines, and electric lighting engines and dynamos.

The following is an abstract of his remarks on the last-mentioned machinery: These were among the latest additions to the engines placed under the care of the sea-going engineer, but they had come into use so rapidly that it was now the practice to fit up cargo steamers, as well as passenger steamers, with them. The difference in the comfort of a ship furnished with electric light, instead of oil lamps, could only be judged by those who had had experience of both. A paper on this subject was read before the institution by Mr. Jamieson, in 1884, since which time considerable advances had been made in perfecting the engine and dynamo for ship work. In the interval, nearly every variety of engine had been tried—turbine, three-cylinder, rotary, single and double acting, open and closed, high and slow speed; but the general opinion appeared to be that the double-acting engine, specially constructed for driving dynamos, was the form which would find the most favour for marine work. At the present time electric light machinery might be classed under two heads—viz., that specially suitable to Admiralty purposes, where the highest economy and efficiency were the principal qualities required; and that appropriate for ordinary merchant steamers, where a good practical engine and dynamo were looked for before economy, except in some of the best Atlantic liners, where combined engines of economical form might be found.

The question of driving dynamos direct from engines or by rope gearing had, the author thought, been settled by the general adoption of the direct-working machine.

The author was of opinion that progress had been largely accelerated by the close specifications issued by the Admiralty, without which latent ability would not have been developed and such great improvements effected in so short a time. The economy of engines and dynamos had been improved, both by increasing the efficiency of the dynamo and by reducing the quantity of water required by the engine itself. Naturally, with a high pressure of steam, combined with the use of the condenser, considerable reduction could be made by way of economy. It would also be seen that these engines had in themselves several advantages over closed engines—namely, accessibility, simplicity, and fair economy, combined with the all-important point of durability. It must not be forgotten that the twin engine with cranks at opposite angles, such as was exclusively used at the Admiralty, had the advantage of working with considerably less vibration than the single-cylinder engine. For the mercantile marine, however, an altogether different type seemed to be preferred. With the exception of some of the largest liners, nearly all vessels were at present being fitted with single-cylinder direct-acting engines and dynamos, the object of the owners being to secure a machine which should run constantly without repair or breakdown, and one which could be readily understood by ordinary marine engineers, and repaired by them when necessary.

The ship-lighting dynamo had been greatly improved during the last year or so, and the drum-wound armature machine was one which had been found to work satisfactorily. The armature consisted of a cast-iron hub mounted on a steel spindle, having laminated plates for the core, the whole being drum-wound on the outside. Every part at all likely to get out of order was visible, and could be readily repaired by those in charge of the machine. The voltage at which the author had found it most convenient to work in merchant ships was 60 volts, which was suitable for glow lamps as well as for projectors.

Bearing in mind that the electric light engine had generally to work harder and longer than any other in the ship, the light being required both when in port and at sea, the matter of economy was of some importance. The efficiency of ordinary ship-lighting dynamos, such as those which had been constructed by the author with double-acting engines, was in some cases as high as 83 per cent.

DUBLIN LIGHTING.

The question of Dublin lighting was not settled at the time of going to press. From the telegrams of our correspondent we gather that the question has been discussed in committee for two or three days, and was adjourned yesterday till to-day (Friday).

The tenders amount to 18, and, according to the advertisement inviting them, "the parties tendering shall be bound to build station, supply, erect, and fix all necessary plant, machinery, engines, boilers, dynamos, conductors, pillars, etc." In response, the following proposals were received, these being opened on 1st November last:

Westinghouse Electric Co.	£52,000	£55,350, reducible to £51,000
Hornsby and Sons	29,904	
Sharp and Kent	—	Partial only
Johnson and Phillips	30,639	
Edmundson and Co.	39,117	
Laing, Wharton, and Down	27,090	
Electrical Engineering Co. of Ireland	29,338	Alternative, £29,825
Irish House-to-House Electrical Co.	37,000	
Woodhouse and Rawson	38,103	
Crompton and Co.	31,354	Alternative, £28,971
Electric Construction Co.	—	Partial only
Ryan and Purcell	23,448	With extras would be £24,472, exclusive of buildings
J. E. H. Gordon and Co.	38,500	
Babcock and Wilcox	5,003	Boilers only
W. T. Goolden and Co.	—	Partial only
Siemens Bros. and Co.	—	Partial only
Latimer Clark, Muirhead, and Co.	21,283	Exclusive of buildings
Drake and Gorham	—	Partial only

These tenders were referred by the Special Committee having the electric lighting in charge to the borough surveyor (Mr. Spencer Harty), and to Mr. Manville, electrical engineer, for analysis and report, and in due course these gentlemen presented their report, in which, among other things, they state—

"The lowest complete tender, without buildings, for plant by a responsible maker is that of Messrs. Hornsby and Sons, for Johnson and Phillips's electrical machinery, and their own engines, with Babcock and Wilcox boilers. Their price, amounting to £25,178, is apparently arrived at by the low cost of the meters, of which no particulars are given; of the main laying, which is on a system not seen in operation by you when inspecting various systems; and by dynamos which have revolving armatures instead of stationary armatures.

"On the whole, we are inclined to think that the work proposed by this firm would not be of as perfect a nature as that proposed by some of the other contractors. The complete tender of the Electrical Engineering Company of Ireland, inclusive of the dearest engines of the three types named by them, and amounting to £28,907, without building, is, perhaps, the most complete total tender, at a moderate price; but in the event of your deciding to accept this tender for all sections, you will notice that we have previously recommended that they be asked to reconsider their system of main laying. The tender of the Irish House-to-House Company is equally satisfactory and complete as the last mentioned, with the exception of their price for the engines and sundries, which are tendered for at an abnormally high price, and if their price under this specification were reduced to the same level as that of the other contractors, their total cost would be nearly exactly the same as that of the Electrical Engineering Company of Ireland—still, of course, excluding buildings.

"A good arrangement with two contractors might be made by selecting the Electrical Engineering Company of Ireland for the engines, boilers, and the public lighting plant, amounting to £16,033, and the Irish House-to-House Company for the alternators, regulating apparatus, transformers, meters, and cables, amounting to £15,244, and making together a total of £31,277, without buildings; and in this case the responsibilities of the two contractors will not in any way intermingle, and the Corporation will have the benefit of the system of main laying proposed by the Irish House-to-House Company, and which meets with our entire approval; or, perhaps, a still better arrangement would be made by dividing the work between three contractors—the Electrical Engineering Company of Ireland, as before, for the engines, boilers, and public lighting plant, amounting to £16,033, and the Irish House-to-House Company for the mains, amounting to £4,578, and Messrs. J. E. H. Gordon and Co., for the alternators, regulating apparatus, transformers and meters, amounting to £8,096, or a total of £28,707. Messrs. Gordon and Co. quote for identically the same dynamos, transformers, and meters as the Irish House-to-House Company, and more than probably by the same makers, and, therefore, you will be getting, by this combination, the same plant for £28,707, as included in the total of £31,277, in combination of the Electrical Engineering Company of Ireland and the Irish House-to-House Company. Assuming that you were to accept the tenders last mentioned, there would still be an amount of £4,000 to be added for the buildings, and a sum of £3,000 for sub-transformer stations, as recommended by some of the contractors, and endorsed by us, making a grand total of £35,707 to put the system in complete working order, and leaving the sum of £1,293 for sundry expenses and contingencies to bring the sum up to £37,000, originally estimated by us. If the Electrical Engineering Company of Ireland's tender were accepted, the grand total would amount to £35,907, without contingencies; and if the second proposition, as above, were carried out, the grand total would be £38,277, without contingencies."

Mr. Manville in his appendix to the city engineer's report says: "The specifications are for two schemes—one on the assumption that a central station is put down with sufficient plant to provide current for 80 arc lamps of about 1,000 c.p. each, and 3,000 incandescent lamps of 16 c.p. each; the other on the assumption that power is provided for the same number of arc lamps for the public lighting, but with sufficient power and enlarged mains for the supply of current to 5,000 lamps of 16 c.p. each for the private lighting. The number of lamps and their arrangement allowed for the public lighting is, in my opinion, amply sufficient for the perfect illumination of those streets, and sufficient amount of spare plant is allowed to effectually guard against chances of a breakdown. The circuits are so arranged that each alternate lamp is on a different circuit, and the temporary extinction of one circuit would not interfere with the public convenience. Allowing that on an average 10 per cent. of the 3,000 lamps are burning day and night, 129,600 Board of Trade units will be sold on this account; and that the balance of the 3,000 lamps are burning on an average 1,000 hours per annum, 162,000 Board of Trade units will be sold on this account; or, together, 291,000 Board of Trade units; that at 7d. per unit will yield a gross revenue of £8,487. 10s., from which the annual maintenance charges of £6,262 have to be deducted, leaving a net revenue of £2,221. Allowing that on an average 10 per cent. of the 5,000 lamps are burning day and night, 180,000 Board of Trade units will be sold on private account; and that the whole of the 5,000 lamps are burning on an average 1,000 hours per annum, 300,000 Board of Trade units will be sold on this account; or together, 480,000 Board of Trade units; that at 7d. per unit will yield a gross revenue of £14,000, from which the annual maintenance charge of £7,915 has to be deducted, leaving a net revenue of £7,085. The cost of the arc lighting—viz., £1,600—must be added to this, making the real net revenue £8,685. The approximation of the revenue depends upon the actual amount of light that will be consumed."

EXHIBITIONS.

BY SYDNEY F. WALKER.

It is devoutly to be hoped that the result of the recent exhibition at Edinburgh, with its heavy call upon the guarantors, and the incident of the gross indignity stated to have been offered to its manager, will have the effect of damping the ardour of would-be exhibition-mongers. To the man of business, with few exceptions, exhibitions are an expense and an unmitigated nuisance. He has to pay for space in which to place his exhibit, for constructing his stall, usually for steam power if he requires it, for an attendant to be always on hand to explain his exhibit to a chance passer-by, possibly an employé of a rival firm. He has to lock up a large quantity of stock, whatever it may be, for months together; and often, in the case of electrical exhibits, at the time of the year when he has the best chance of selling them. To crown all, if he is not in constant attendance, say if the exhibition is held in a different part of the country from where his works are situate, he has to pay to go into the exhibition to see his own exhibit. At the Newcastle Exhibition, for instance, the writer, whose firm had a stall there, when spending a few days in the town, wrote to the exhibition committee asking for a pass, and was refused. The executive secretary replied that the writer might have a ticket for 15s., the usual daily entrance fee being 1s. But the exhibitor's troubles are not ended even yet. He is hampered at every step. His stall must not be above a certain height; must not contain this or that. He must not do this or that without the consent of the committee, and as a climax he takes all the risk, so far as his stall is concerned, of fire, water, or any damage to his goods of any kind; though, by the arrangements made, he is absolutely in the hands of the officials as to his security from damage from any of the above causes. He is afforded no protection from theft, for instance.

Then as to his stall. He must be thankful to get this wherever an omnipotent committee may place him. He may have arranged for a stall of a certain size, and have got all his fittings ready, and suddenly be informed that he can only have half the space he has applied for. If his stall is poked away in some corner where no one is likely to pass, unless it be a straggler who has lost his way in the labyrinth usually presented by these exhibitions, so that all the expense he has incurred will be practically thrown away, even under the most favourable circumstances, there is no redress. The omnipotent committee has got his money, and will keep it. He may grin and bear it as best he can. And even the above do not represent all the troubles of the exhibitor. His apparatus is open to the inspection of all his rivals. Unless his particular specialities are either very carefully protected by a patent, and the £10,000 necessary in these days to support a patent, or are of so little use to anyone as not to be worth the trouble, he will assuredly have them copied. Further, if he exhibits any apparatus in work every chance slip or breakdown is noted to his disadvantage, even by the very men whom his exhibit is intended to benefit. But the cream of the whole thing is that in nearly all the exhibitions that have been held of late years the vast majority of the public do not go to see the exhibits at all. There may be an odd thing or two of startling novelty, such as the phonograph, that they will crowd to see and hear; but as a rule they go to hear the band, see their friends, the beautiful display of lights, of the illuminated fountains, and so on. It was delightful, for instance, during the Manchester and Glasgow Exhibitions after the day's work was done to take the train out to the exhibition, enjoy an *al fresco* tea under the trees, listening the while to the strains of the really excellent bands that were provided, see the fountains play later on, and then go back to one's hotel to bed. It was much better than sitting in the hotel all the evening, or going to a stuffy theatre, or even walking about the streets. And all this was provided for the modest charge of one shilling, a really good tea being provided for another shilling. From the point of view of the general public this sort of thing is charming. From that of the exhibitor, who pays for it all and usually gets very little in return, it is the reverse of charming.

It is hardly pleasant to an exhibitor who has gone to great expense to find the public who he is entertaining, in the hope that they will pay him in kind, deserting his stall for the greater attractions in the grounds. But the general public, after all, is not so very much to blame. Looking at exhibits which one does understand is very tiring if carried on for long. Looking at those one does not know the A B C of is positive hard work if it is done conscientiously; and an awful bore if it is not. The music, the grounds, the Turkish cafés, and all the lighter attractions are thrown in to disguise the solid matter inside the building, just as the spoonful of jam was used to disguise the nauseous but wholesome powder we used some of us to be forced to take in our young days. That great overgrown child, the British public, would not come twice if it was all solid meat. He must have a few lighter things thrown in, which he takes very kindly to—at the expense of that willing horse, the exhibitor.

The writer has met men, too, rare birds, who have told him that exhibitions paid them. He is strongly inclined to believe, though, that they were dazzled by a few orders and had not counted all the cost; further, there are cases where it is quite possible to make an exhibition pay even an exhibitor. If you can have a handsome showcase made, taking very small floor space, but able to contain samples of all the apparatus you make, and requiring no attendance, not even dusting, then you may possibly get a return for your outlay. The additional cost for each exhibition after the first outlay being very trifling, almost any orders you get will repay you, provided the value of the apparatus locked up in the case is not too great, and that you sustain no damage from fire, water, mischief, etc. But you can get all this at any railway station without going to the trouble of building an exhibition for it; and you will be far more certain of an appreciative public. To a traveller waiting for a train at a railway station everything is an attraction that will pass away the time, while there are no sweet strains of delightful bands in the vicinity to distract the attention.

There is also another case where exhibitions may pay the exhibitor. If a firm or company be newly started, with a new thing which it is important should be placed before the public, large numbers of them, quickly, then the exhibition stands unrivalled. In fact, with companies having the capital, the plan would be to have an exhibition, gardens, illuminated fountains, and all the paraphernalia, all to themselves. There would be a far greater chance of a remunerative return than in taking a stall in someone else's exhibition. When a visitor could not move, or look, or speak without being reminded of the presence of John Jones and Co., he could not help being impressed with the fact that John Jones and Co. were very much in existence, and that enterprising firm would have accomplished the great object of all advertising—viz., bringing their living presence home to the buyer.

The writer has heard men of business who had no particular novelty to bring forward say that exhibitions have paid them. He believes that they are mistaken; that if they had expended the amount which their exhibit cost them in other methods of advertising they would have secured a far greater return. It is possible that in many cases an unexpected source of business has been tapped through an exhibition that would not have occurred to the exhibitor to seek after, but the cases where this occur are few, and probably a more careful and diligent use of the ordinary resources of advertising would have done it equally as well, if possibly a little later.

Another point that should not be overlooked in connection with this matter, and which forms a large part of the difficulty of securing a profitable return for the outlay, is the almost invariably expensive management of the whole affair. Business men have rarely anything to do with exhibitions beyond their own exhibits. It is nearly always left entirely to men who have no business experience, and though the result is more often satisfactory from the engineer's point of view—all goes off well—than one would expect, it is nearly always attained at a much higher cost than would be necessary under ordinary commercial conditions, and that notwithstanding that apparently every possible source of income is utilised to the very utmost. The poor exhibitor is bled as long as he will stand it, under every conceivable disguise. But what ought to be a handsome surplus is dribbled away in petty expenses, and in other ways that the ordinary man of business is always on the look-out for Even when there is a surplus, with no declared object in view no thought of the exhibitor is taken. No one thinks of helping him with his expenses. The surplus is left somewhere in a bank for lawyers to fight over.

Further, the temporary nature of the structure and all connected with the exhibition, necessarily renders it a very expensive method of placing almost anything before the public. Exhibition buildings must be substantially put up—usually to be pulled down in six months at latest, and the old materials sold. Grounds must be made temporarily decorative in some parts, while in others considerable damage is done which has to be made good. And all this—all the salaries, all the waste, all the amusement, everything, in fact—comes out of the exhibitor's pocket, while he is very lucky indeed if he gets a return—in profit on orders taken directly or indirectly—of small percentage of his outlay.

THE ELECTROMAGNET.*

. BY PROF. SILVANUS P. THOMPSON, D.SC., B.A., M.I.E.E

(*Concluded from page 77.*)

Such little motors are often now used for spinning Geissler's vacuum tubes. In these motors the iron rim is fixed, and the electromagnet rotates. The pole of the electromagnet finds itself a certain distance away from the iron ring, it tries to get nearer. The only way it can get nearer is by swinging round, and so it gradually approaches, and as it approaches the place where it is nearest to the internal projection of the rim the current is cut off, and it swings further. This mode may be likened to a cam in a mechanical movement. It is, in fact, nothing else than an electromagnetic cam. There are other devices too, which are more like electromagnetic linkages. If you curve the poles or shape them out you may obtain actions which are like that of a wedge on an inclined plane. There is an electromagnet in one of Paterson and Cooper's arc lamps wherein the pole-piece, coming out below the magnet, has a very peculiar shape, and the armature is so pivoted with respect to the magnet, that as the armature approaches the core as a whole its surface recedes from that of the pole-piece, the effect being that the pull is equalised over a considerable range of motion. There is a somewhat similar device in De Puydt's pattern of arc lamp.

---

* Cantor lectures, delivered before the Society of Arts.

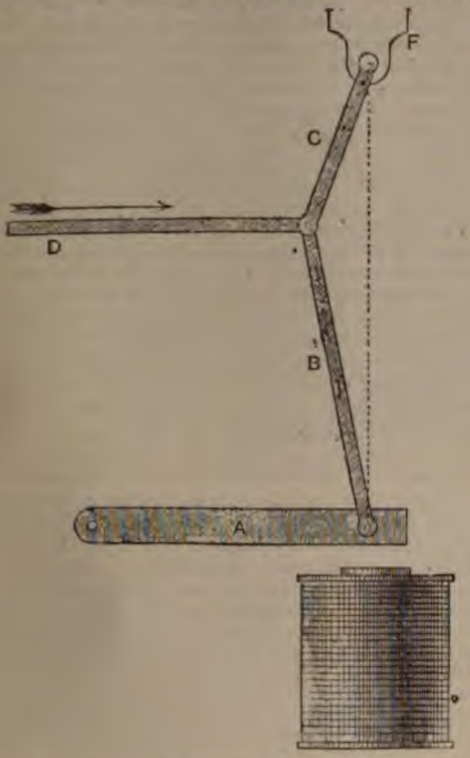


Fig. 68.—Froment's Equaliser with Stanhope Lever.

Here is another device for oblique approach, made by Froment. In the gap in the circuit of the magnet a sort of iron wedge is put in, which is not attracted squarely to either face, but comes in laterally between guides. Another of Froment's equalisers, or distributors, consists of a parallel motion attachment for the armature, so that oblique approach may take place without actual contact. Here, Fig. 68, is another mechanical method of equalising devised by Froment, and used by Le Roux. You know the Stanhope lever, the object of which is to transform a weak force along a considerable range into a powerful force of short range. Here we use it backwards. The armature itself, which is attracted with a powerful force of short range, is attached to the lower end of the Stanhope lever, and the arm attached to the knee of the lever will deliver a distributed force over quite a different range. One way, not of equalising the actual motion over the range but of counterbalancing the variable attractive force, is to employ a spring instead of gravity to control the armature. So far back as 1838, Edward Davy, in one of his telegraphic patents, described the use of a spring, Fig. 69, to hold back the armature. Davy preceded Morse in the use of a spring to pull back the armature. There is a way of making a spring act against an armature more stiffly as the pull gets greater. In this method there is a spring with various set screws set up against it, and which come into action at different ranges, so as to alter the stiffness of the spring, making it virtually stiffer as the armature approaches the poles. Yet another method is to employ, as the famous conjuror Robert Houdin did, a rocking lever. Fig. 70 depicts one of Robert Houdin's equalisers. The pull of the electromagnet on the armature acts on a curved lever which works against a second one; the point of application of force between the one and the other altering with their position. When the armature is far away from the pole, the leverage of the first lever on the second lever is great. When the armature gets near, the leverage of the first lever on the second is comparatively small. This employment of the rocking lever was adopted from Houdin by Duboscq, and put into the Duboscq arc lamp, where the regulating mechanism at the bottom of the lamp contains a rocking lever. Here, upon the lecture table, is a Duboscq's arc lamp. In this pattern, Fig. 71, one lever, B, which is curved, plays against another, A, which is straight. A similar mechanism is used for equalising the action in the Serrin arc lamp, where one of the springs that holds up the jointed parallelogram frame is applied at the end of a rocking lever to equalise the pull of the regulating electromagnet. In this lamp there is also introduced the principle of oblique approach; for the armature of the electromagnet is not allowed to travel straight towards the poles of the magnet, but is pulled up obliquely past it.

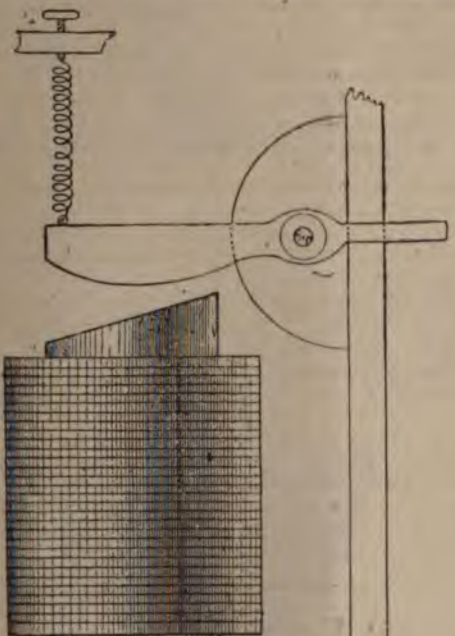

Fig. 69.—Davy's Mode of Controlling Armature by Spring.

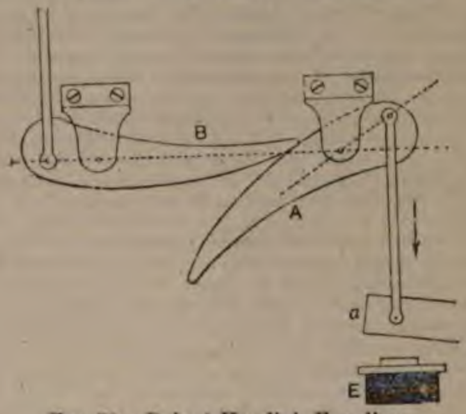

Fig. 70.—Robert Houdin's Equaliser.

Another device for equalising the pull was used by Wheatstone in his step-by-step telegraph in 1840. A hole is pierced in the armature, and the end of the core is formed into a projecting cone, which passes through the aperture of the armature, thereby securing a more equable force and a longer range. The same device has reappeared in recent years in the form of electromagnet used in the Thomson-Houston arc lamp, and in the automatic regulator of the same firm.

POLARISED MECHANISM: USES OF PERMANENT MAGNETS.

We must now turn our attention to one class of electromagnetic mechanism which ought to be carefully distinguished from the rest. It is that class in which, in addition to the ordinary electromagnet, a permanent magnet is employed. Such an arrangement is generally referred to as a polarised mechanism. The objects for which the permanent magnet is introduced into the mechanism appear to be in different cases quite different. I am not sure whether this is clearly recognised, or whether a clear distinction has even been drawn between three entirely separate purposes in the use of a permanent magnet in combination with an electromagnet. The first purpose is to secure unidirectionality of motion, the second is to increase the rapidity of action and of sensitiveness to small

690007

LA LUMIÈRE ÉLECTRIQUE OCT. 91 Boulevard des Italiens, PARIS

currents, the third to augment the mechanical action of the current.

(*a*.) *Unidirectionality of Motion.*—In an ordinary electromagnet it does not matter which way the current circulates. No matter whether the pole is north or south, the armature is pulled, and on reversing the current the armature is also pulled. There is a rather curious old experiment which Sturgeon and Henry showed, that if you have an electromagnet with a big weight hanging on it, and you suddenly reverse the current, you reverse the magnetism, but it still holds the weight up ; it does not drop. It has not time to drop before the magnet is charged up again with magnetic lines the other way on. Whichever way the magnetism traverses the ordinary soft iron electromagnet the armature is pulled. But if the armature is itself a permanent magnet of steel, it will be pulled when the poles are of one sort, and pushed when the poles are reversed—that is to say, by employing a polarised armature you can secure unidirectionality of motion in correspondence with the current. One immediate application of this fact for telegraphic purposes is that of duplex telegraphy. You can send two messages at the same time and in the same direction to two different sets of instruments, one set having ordinary electromagnets, with a spring behind the armature of soft iron, which will act simply independently of the direction of the current, depending only on its strength and duration ; and another set having electromagnets with polarised armatures, which will be affected not by the strength of the current, but by the direction of it. Accordingly, two completely different sets of messages may be sent through that line in the same direction at the same time.

Another mode of constructing a polarised device is to attach the cores of the electromagnet to a steel magnet, which imparts to them an initial magnetisation. Such initially-magnetised electromagnets were used by Brett in 1848, and by Hjörth in 1850. A patent for a similar device was applied for in 1870 by Sir William Thomson, and refused by the Patent Office. In 1871, S. A. Varley patented an electromagnet having a core of steel wires united at their ends.

Wheatstone used a polarised apparatus consisting of an electromagnet acting on a magnetised needle. He patented, in fact, in 1845, the use of a needle permanently magnetised to be attracted one way or the other between the poles of an electromagnet. Sturgeon had described the very same device in the *Annals of Electricity* in 1840. Gloesner claims to have invented the substitution of permanent magnets for mere armatures in 1842. In using polarised apparatus it is necessary to work, not with a simple current that is turned off and on, but with reversed currents. Sending a current one way will make the moving part move in one direction, reversing the current makes it go over to the other side. The mechanism of that particular kind of electric bell that is used with magneto-electric calling apparatus furnishes an excellent example of a polarised construction. With these bells no battery is used, but there is a little alternate-current dynamo, worked by a crank. The alternate currents cause the pivoted armature in the bell to oscillate to right and left alternately, and so throw the little hammer to and fro between the two bells.

(*b*.) *Rapidity and Sensitiveness of Action.*—For relay work polarised relays are often employed, and have been for many years. Here on the table is one of the Post Office pattern of standard relay, having a steel magnet to give magnetism permanently to a little tongue or armature which moves between the poles of an electromagnet that does the work of receiving the signals. In this particular case the tongue of polarised relay works between two stops, and the range of motion is made very small in order that the apparatus may respond to very small currents. At first sight it is not very apparent why putting a permanent magnet into a thing should make it any more sensitive. Why should permanent magnetism secure rapidity of working? Without knowing anything more, inventors will tell you that the presence of a permanent magnet increases the rapidity with which it will work. You might suppose that permanent magnetism is something to be avoided in the cores of your working electromagnets, otherwise the armatures would remain stuck to the poles when once they had been attracted up. Residual magnetism would, indeed, hinder the working unless you have so arranged matters that it shall be actually helpful to you. Now for many years it was supposed that permanent magnetism in the electromagnet was anything but a source of help. It was supposed to be an unmitigated nuisance, to be got rid of by all available means, until, in 1855, Hughes showed us how very advantageous it was to have permanent magnetism in the cores of the electromagnet. Here, Fig. 51, is the drawing of Hughes's magnet to which I referred in Lecture III. A compound permanent magnet of horseshoe shape is provided with coils on its pole-pieces, and there is a short armature on the top attached to a pivoted lever and a counteracting spring. The function of this arrangement is as follows. That spring is so set as to tend to detach the armature, but the permanent magnet has just enough magnetism to hold the armature on. You can, by screwing up a little screw behind the spring, adjust these two contending forces, so that they are in the nicest possible balance ; the armature held on by the magnetism, and the spring just not able to pull it off. If, now, when these two actions are so nearly balanced you send an electric current round the coils, if the electric current goes one way round it just weakens the magnetism enough for the spring to gain the victory, and up goes the armature. This apparatus then acts by letting the armature off when the balance is upset by the electric current ; and it is capable of responding to extremely small currents. Of course, the armature has to be put on again mechanically, and in Hughes's type-writing telegraph instruments it is put on mechanically between each signal and the next following one. The arrangement constitutes a distinctive piece of electromagnetic mechanism.

(*c*.) *Augmenting Mechanical Action of Current.*—The third purpose of a permanent magnet to secure a greater mechanical action of the varying current is closely bound up with the preceding purpose of securing sensitiveness of action. It is for this purpose that it is used in telephone receivers ; it increases the mechanical action of the current, and therefore makes the receiver more sensitive. For a long time this was not at all clear to me ; indeed, I made experiments to see how far it was due to any variation in the magnetic permeability of iron at different stages of magnetisation, for I found that this had something to do with it, but I was quite sure it was not all. Prof. George Forbes gave me the clue to the true explanation ; it lies in the law of traction with which you are now familiar, that the pull between a magnet and its armature is proportional to the square of the number of magnetic lines that come into action. If we take N, the number of magnetic lines that are acting through a given area, then to the square of that the pull will be proportional. If we have a certain number of lines, N, coming permanently to the armature, the pull is proportional to N^2. Suppose the magnetism now to be altered—say, made a little more, and the increment be called $d\,\mathsf{N}$; so that the whole number is now $\mathsf{N}+d\,\mathsf{N}$. The pull will now be proportional to the square of that quantity. It is evident that the motion will be proportional to the difference between the former pull and the latter pull. So we will write out the square of $\mathsf{N}+d\,\mathsf{N}$, and the square of N, and take the difference.

$$\begin{array}{ll} \text{Increased pull, proportional to......} & \mathsf{N}^2+2\,\mathsf{N}\cdot d\,\mathsf{N}+d\,\mathsf{N}^2\;; \\ \text{Initial pull, proportional to .. ..} & \mathsf{N}^2 \qquad\qquad\qquad\;\; ; \\ \cline{2-2} \text{Subtracting ; difference is ......} & 2\,\mathsf{N}\cdot d\,\mathsf{N}+d\,\mathsf{N}^2. \end{array}$$

We may neglect the last term, as it is small compared with the other. So we have, finally, that the change of pull is proportional to $2\,\mathsf{N}\cdot d\,\mathsf{N}$. The alteration of pull between the initial magnetism and the initial magnetism with the additional magnetism we have given to it, turns out to be proportional, not simply to the change of magnetism, but also to the initial number N that goes through it to begin with. The more powerful the pull to begin with, the greater is the change of pull when you produce a small change in the number of magnetic lines. That is why you have this greater sensitiveness of action when using Hughes's electromagnets, and greater mechanical effect as the result of applying permanent magnetism to the electromagnets of to telephone receivers.

ELECTROMAGNETIC MECHANISM.

There are some other kinds of electromagnetic mechanism to which I must briefly invite your attention, as forming an important part of this great subject. Of one of these the mention of permanent magnets reminds me.

MOVING COIL IN PERMANENT MAGNETIC FIELD.

A coil traversed by an electric current experiences mechanical forces if it lies in a magnetic field ; the force being proportional to the intensity of the field. Of this principle the mechanism of Sir W. Thomson's syphon recorder is a well-known example. Also those galvanometers which have for their essential part a movable coil suspended between the poles of a permanent magnet, of which the earliest example is that of Robertson (see *Encyclopædia Britannica*, ed. viii., 1855), and of which Maxwell's suggestion, afterwards realised by D'Arsonval, is the most modern. Siemens has constructed a relay on a similar plan.

MAGNETIC ADHERENCE.

There are a few curious pieces of apparatus devised for increasing adherence electromagnetically between two things. Here is an old device of Nicklès, who thought he would make a new kind of rolling gear. Whether it was a railway wheel on a line, or whether it was going to be an ordinary wheel gearing, communication of motion was to be made from one wheel to another, not by cogs or by the mere adherence of ordinary friction, but by magnetic adherence. In Fig. 72 there are shown two iron wheels

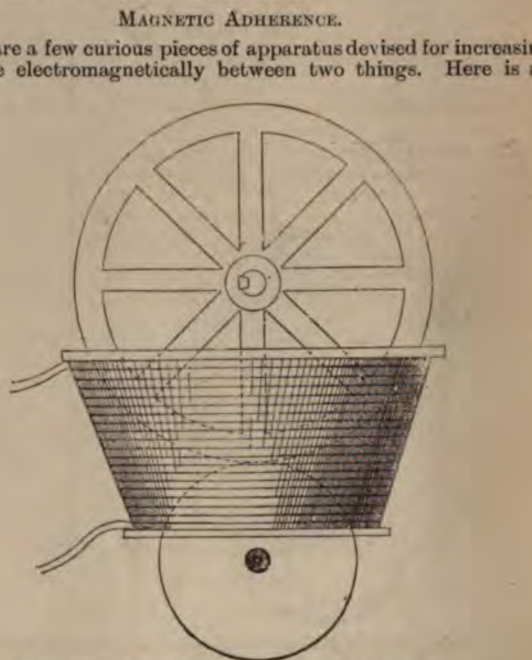

FIG. 72.—Nicklès's Magnetic Friction Gear.

rolling on one another, with a sort of electromagnetic jacket around them, consisting of an electric current circulating in a coil, and causing them to attract one another and stick together with magnetic adherence. In Nicklès's little book on the subject there are a great number of devices of this kind described, including a magnetic brake for braking railway waggons, engines, and carriages, applying electromagnets either to the wheels or else to the line, to stop the motion whenever desired. The notion of using an electromagnetic brake has been revived quite recently in a much better form by Prof. G. Forbes and Mr. Timmis, whose particular form of electromagnet, shown in Fig. 73, is peculiarly interesting, being a better design than any I have ever seen for securing powerful magnetic traction for a given weight of iron and copper. The magnet is a peculiar one ; it is represented here as cut away to show the internal construction. There is a sort of horseshoe made of one grooved rim, the whole circle of coil being laid embedded in the groove. The armature is a ring which is attracted down all round, so that you have an extremely compact magnetic circuit around the copper wire at every point. The magnet part is attached to the frame of the waggon or carriage, and the ring armature is attached to the wheel or to its axis. On switching on the electric current the rim is powerfully pulled, and braked against the polar surface of the electromagnet.

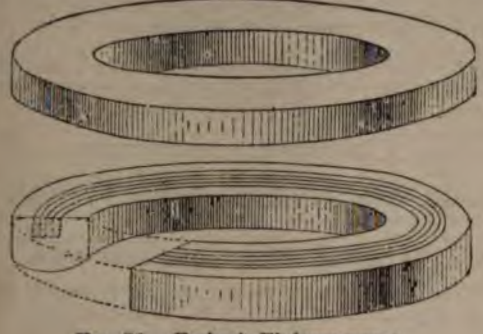

FIG. 73.—Forbes's Electromagnet.

Forbes's arrangement appears to be certainly the best yet thought of for applying a magnetic brake to the wheels of a railway train.

Another, but quite distinct, piece of mechanism depending on electromagnetic adherence is the magnetic clutch employed in Gülcher's arc lamp.

Repulsion Mechanism.

Then there are a few pieces of mechanism which depend on repulsion. In 1850 a little device was patented by Brown and Williams, consisting, as shown in Fig. 74 of an electromagnet which repelled part of itself. The coil is simply wound on a hollow tube, and inside the coil is a piece, B, of iron, bent as the segment of a cylinder to fit in, going from one end to the other. Another little iron piece, A, also shaped as the segment of a tube, is pivoted in the axis of the coil. When these are magnetised one tends to move away from the other, they being both of the same polarity. Of late there have been many ampere-meters and voltmeters made on this plan of producing repulsion between the parallel cores.

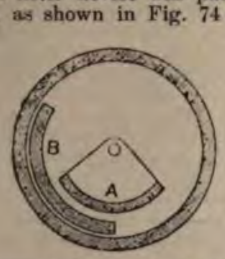

FIG. 74.—Electromagnetic Mechanism Working by Repulsion.

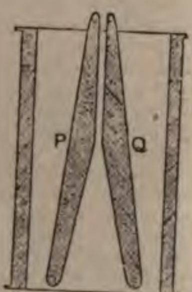

FIG. 75.—Repulsion between Two Parallel Cores.

Here, Fig. 75, is another device of recent date, due to Maikoff and De Kabath. Two cores of iron, not quite parallel, pivoted at the bottom, pass up through a tubular coil. When both are magnetised, instead of attracting one another they open out ; they tend to set themselves along the magnetic lines through that tube. The cores being wide open at the bottom tend to open also at the top.

Electromagnetic Vibrators.

Then there is a large class of mechanisms about which a whole chapter might be written—namely, those in which vibration is maintained electromagnetically. The armature of an electromagnet is caused to approach and recede alternately with a vibrating motion, the current being automatically cut off and turned on again by a self-acting brake. The electromagnetic vibrator is one of the cleverest things ever devised. The first vibrating electromagnetic mechanism ever made was exhibited here in this room in 1824 by its inventor, an Englishman named James Marsh. It consisted of a pendulum vibrating automatically between the poles of a permanent magnet. Later, a number of other vibrating devices were produced by Wagner, Neef, Froment, and others. Most important of all is the mechanism of the common electric trembling bell, invented by a man whose very name appears to be quite forgotten—John Mirand. How many of the millions of people who use electric bells know the name of the man who invented it? John Mirand, in the year 1850, put the electric bell practically into the same form in which it has been employed from that day to this. The vibrating hammer, the familiar push-button, the indicator, or annunciator, are all of his devising, and may be seen depicted in the specification of his British patent just as they came from his hand.

Time alone precludes me from dealing minutely with these vibrators, and particularly with the recent work of Mercadier and that of Langdon-Davies, whose researches have put a new aspect on the possibilities of harmonic telegraphy. Langdon-Davies's rate-governor is the most recent and perfect form of electromagnetic vibrator.

Indicator Movements.

Upon the table here are a number of patterns of electric bells, and a number also of the electro-mechanical movements or devices employed in electric bell work, some of which form admirable illustrations of the various principles that I have been laying down. Here is an iron-clad electromagnet ; here a tripolar magnet ; here a series of pendulum motions of various kinds ; here is an example of oblique pull ; here is Jensen's indicator, with lateral pull ; here is Moseley's indicator, with a coil and plunger, iron-clad ; here is a clever device in which a disc is drawn up to better the magnetic circuit. Here, again, is Thorpe's semaphore indicator, one of the neatest little pieces of apparatus, with a single central core surrounded by a coil, while a little strip of iron coming round from behind serves to complete the circuit all save a little gap. Over the gap stands that which is to be attracted, a flat disc of iron, which, when it is attracted, unlatches another disc of brass which forthwith falls down. It is an extremely effective, very sensitive, and very inexpensive form of annunciator. The next two are pieces of polarised mechanism having a motion directed to one side or the other, according to the direction of the current. From the back-board projects a small straight electromagnet. Over it is pivoted a small arched steel magnet, permanently magnetised, to which is attached a small signal lever bearing a red disc. If there is a current flowing one way then the magnet that straddles over the pole of the electromagnet will be drawn over in one direction. If I now reverse the current, the electromagnet attracts the other pole of the curved magnet. Hence this mechanism allows of an electrical replacement, without compelling the attendant to walk up to the indicator board. The polarised apparatus for indicators has this advantage, that you can have electrical as distinguished from mechanical replacement.

The Study of Electromagnetic Mechanism.

The rapid survey of electromagnetic mechanisms in general has necessarily been very hurried and imperfect. The study of it is just as important to the electrical engineer as is the study of mechanical mechanism to the mechanical engineer. Incomplete as is the present treatment of the subject, it may sufficiently indicate to other workers useful lines of progress, and so fitly be appended to these lectures on the electromagnet. In a very few years we may expect the introduction into all large engineering shops of electromagnetic tools. On a small scale, for driving dental appliances, electromagnetic engines have long been used. Large machine tools, electromagnetically worked, have already begun to make their appearance. Some such were shown at the Crystal Palace in 1881, by Mr. Latimer Clark, and more recently, Mr. Rowan, of Glasgow, has devised a number of more developed forms of electromagnetic tools.

Suppression of Sparking.

It now remains for me to speak briefly of the suppression of sparks. There are some half-dozen different ways of trying to get rid of the sparking that occurs in the breaking of an electric circuit whenever there are electromagnets in that circuit. Many attempts have been made to try and get rid of this evil. For instance, one inventor employs an air blast to blow out the spark just at the moment it occurs. Another causes the spark to occur under a liquid. Another wipes it out with a brush of asbestos cloth that comes immediately behind the wire and rubs out the spark. Another puts on a condenser to try and store up the energy. Another tries to put on a long thin wire or a high resistance of liquid, or something of that kind, to provide an alternate path for the spark, instead of jumping across the air and burning the contacts. There exist some half-score, at any rate, of that kind of device. But there are devices that I have thought it worth while to examine and experiment upon, because they depend merely upon the mode of construction adopted in the building of the electromagnet, and they have each their own qualities. I have here five straight electromagnets, all wound on bobbins the same size, for which we shall use the same iron core and the same current for all. They are all made, not only with bobbins of the same size, but their coils consist as nearly as possible of the same weight of wire. The first one is wound in the ordinary way; the second one has a sheath of copper wound round the interior of the bobbin before any wire is put on. This was a device, I believe, of the late Mr. C. F. Varley, and is also used in the field magnets of Brush dynamos. The function of the copper sheath is to allow induced currents to occur, which will retard the fall of magnetism, and damp down the tendency to spark. The third one is an attempt to carry out that principle still further. This is due to an American of the name of Paine, and has been revived of late years by Dr. Aron, of Berlin. After winding each layer of the coil a sheath of metal foil is interposed so as to kill the induction from layer to layer. The fourth one is the best device hitherto used—namely, that of differential winding, having two coils connected so that the current goes opposite ways. When equal currents flow in both circuits there is no magnetism. If you break the circuit of either of the two wires the core at once becomes magnetised. You get magnetism on breaking, you destroy magnetism on making the circuit. It is just the inverse case to that of the ordinary electromagnet. There the spark occurs when magnetism disappears, but here, since the magnetism disappears when you make the circuit, you do not get any spark at make, because the circuit is already made. You do not get any at break, because at break there is no magnetism. The fifth and last of these electromagnets is wound according to a plan devised by Mr. Langdon-Davies, to which I alluded in the middle of this lecture, the bobbin being wound with a number of separate coils in parallel with one another, each layer being a separate wire, the separate ends of all the layers being finally joined up. In this case there are 15 separate circuits; the time-constants of them are different, because, owing to the fact that these coils are of different diameters, the coefficient of self-induction of the outer layers is rather less, and their resistance, because of the larger size, rather greater than those of the inner layers. The result is that instead of the extra currents running out all at the same time, it runs out at different times for these 15 coils. The total E.M.F. of self-induction never rises so high, and it is unable to jump a large air gap, or give the same bright spark as the ordinary electromagnet would give. We will now experiment with these coils. The differential winding gives absolutely no spark at all, and second in merit comes No. 5, with the multiple-wire winding. Third in merit comes the coil with intervening layers of foil. The fourth is that with copper sheath. Last of all, the electromagnet with ordinary winding.

CONCLUSION.

Now let me conclude by returning to my starting point—the invention of the electromagnet by William Sturgeon. Naturally you would be glad to see the counterfeit presentment of the features of so remarkable a man, of one so worthy to be remembered amongst distinguished electricians and great inventors. Your disappointment cannot be greater than mine when I tell you that all my efforts to procure a portrait of the deceased inventor have been unavailing. Only this I have been able to learn as the result of numerous enquiries; that an oil painting of him existed a few years ago in the possession of his only daughter, then resident in Manchester, whose address is now unfortunately unknown. But if his face must remain unknown to us, we shall none the less proudly concur in honouring the memory of one whose presence once honoured this hall wherein we are met, and whose work has won for him an imperishable name.

LEGAL INTELLIGENCE.

SAMUEL v. THE LONDON ELECTRIC SUPPLY COMPANY.

A Case of Trespass by Electric Light Men.

In the Queen's Bench Division of the High Court of Justice, on Monday last, this case came before Mr. Justice Grantham and a common jury.

Mr. Winch, Q.C., and Mr. Henry Kisch were counsel for the plaintiff; Mr. Lockwood, Q.C., and Mr. A. M. Bremner appeared for the defendants.

It was an action to recover damages for trespass to the plaintiff's stable, situate in Brad-street, close to the bridge of the South-Eastern Railway Company at Waterloo Bridge. The defendants, while disputing part of the plaintiff's claim as regards a horse paid £15 into court to satisfy any loss the plaintiff might have sustained in respect of any hay damaged. According to the plaintiff's case, the servants of the company trespassed on to his roof at the stable and adjoining loose box while cutting the cable which runs to Deptford to test it. He said that on December 5, 6, and 7, 1889, quantities of hay amounting to four loads, worth £12, were damaged by rain-water penetrating through the roof. As to the loose box next door, he said that a valuable cart horse, which he had purchased two years ago as a four-year-old for £40, and which was worth at least £60, as being capable of drawing 2½ tons, had through the wet and damp caught cold and contracted a kidney disease, of which it subsequently died. Before this happened the horse was sold and fetched £9. 1s. 6d., and this was deducted from the amount sued for. The case for the defence was that, as to the loss on the hay, it was very much exaggerated; that not more than a dozen or 15 trusses were injured, as one of the gentlemen connected with the company deposed to seeing, on December 17, the day after the plaintiff gave them notice that the hay and roof were damaged. They said that there had been nobody walking on the roof at all after October, but they admitted having replaced, after application, 156 slates on the stable (No. 1) after their attention had been called to the matter. As to the loose box (No. 2), they said that their workmen had never been on the roof at all, and that if the horse caught cold it must have been in the other stable.

Mr. Justice Grantham, in summing up, said the strange thing was that, if the mischief was done to the roof in October, no injury was apparent in the stable before December 5, 1889. But that perhaps might be accounted for if the season had been dry during the intervening time. The defendants contended that the price of the horse was exaggerated; but it did not seem unreasonable to ask £60 for a strong cart horse of such draught power, which cost £40 as a four-year-old two years ago. If the jury found a verdict for the plaintiff, they would say how much he was entitled to recover on the item of the hay, and how much as regards the horse, if its injuries were due to the negligence of the defendants' servants.

The jury retired to consider their verdict, and, after an absence of 45 minutes, returned into court with a verdict for the plaintiff for £65, inclusive of the £15 paid into court.

COMPANIES' MEETINGS.

NATIONAL TELEPHONE COMPANY.

A meeting of this Company was held on Thursday morning at the Cannon-street Hotel, Mr. F. R. Leyland, president of the Company, in the chair. The meeting was very largely attended, many shareholders being unable to obtain seats.

The **Chairman** said that this was not one of their usual meetings, it was more in the nature of a conference between Directors and shareholders for the purpose of explaining the present position of the Company now that the first of their master patents had expired. Referring to the accounts (which had not been audited) as made up to 31st October last, that was for the first six months of the Company's current year, he said the Company had earned a net profit of £108,170. 19s. 11d. This sum, together with £11,113. 9s. 7d. brought forward from last account, left an amount of £119,284. 9s. 6d. standing to the credit of profit and loss account. Out of that sum they had paid an interim dividend amounting to £62,973, and they had in hand £56,311, which, together with the profits that would be made in the second six months of the year, they would have to dispose of at their next annual general meeting. These figures were very satisfactory. The revenue account to April, 1890, showed a net profit of £185,754; the same profit on that account for the six months of this year was £104,765. If they divided £185,754 by one-half they would get £92,700, about, but instead of that they had for the six months £104,765. Last year they called up £260,000 for an issue of 52,000 new ordinary shares, and they (the Board) assured the shareholders that that new capital would give them just as good a profit as the old capital. That view had been realised. The revenue on April 30, 1890, showed a percentage on capital at that time of 8¾ per cent. Out of that they paid 6 per cent. dividend, and carried the other 2¾ per cent. to reserve fund principally, and a part forward. They then issued £260,000 new capital. What was the increased profit on revenue account for the six months? It was £11,891, and that gave them as nearly as possible 8¾ per cent., which was just the same thing, but they had the dividend on a larger capital, and that was a desirable thing, because the bigger the Company was the stronger and more impregnable they were against competition. Between October 31 and December 31, 1890, their rates remained the same, and there was the ordinary normal increase of the business, so that the ratio in the profits would be maintained, and, he thought, slightly exceeded. After that date, on 1st January, when the first master patent expired, they thought it wise, although the second master patent did not expire until July, 1891, to make a reduction in rates. The first result of that was, of course, that the revenue was reduced; but, on the other hand, they believed the reduction would bring in a great number of additional subscribers who would not otherwise have come on to their system, and in that way they would recoup the whole of that loss, and, he thought, more quickly than they would imagine. The net increase in the number of subscribers over the six months from April to October last, was 1,940. Dividing that by the number of weeks, it would give them an average per week of about 75. The increase in subscribers for the first three weeks of this month, January, had been 651. If that increase was kept up, and he saw no reason why it should not be, it would be a comparatively short time before the whole of the loss of revenue caused by the reduction in rates would be recouped, and they would have an infinitely stronger business. He did not think the possession of a monopoly such as they had enjoyed was an unmixed blessing. He would now deal with the capital expenditure of the Company. Every increase of business necessarily involved, in that Company, an increased expenditure on capital account. They could not link up a fresh town or put up an additional subscriber without this expenditure being increased. It was unavoidable so long as they pursued their present policy of extending business and covering the ground, which was their sheet anchor. They had expended in the first six months of this year (Company's year) on the construction of exchange, trunk and branch lines, the large sum of £96,970. A considerable portion of that, £40,000 or £45,000, went in linking up different towns in the provinces. The total number of towns linked was 244, and they were now in communication with each other. That was what he thought would prove to be the salvation of the Company, because any competitor could only give a local service unless he was prepared to spend the enormous amount of money they had spent in linking up the different towns in the kingdom. The greater portion of that £96,000 was now yielding a very satisfactory and growing revenue. They were gradually bringing every town that offered a fair chance of revenue into communication with the main centres in the provinces. If they had not pursued this policy of covering the ground, they would have had plenty of people glad to take the business. At the last meeting, speaking on this point, he said that increased capital must be obtained, and he told them that the Directors had not made up their minds as to whether the best mode of raising it would be by preference shares or by debentures. They had considered the matter thoroughly since, and had come to the conclusion that the best thing for the Company was to raise that money in debentures. He thought it was the cheapest way, and it avoided many of the complications arising from preference shares, of which there were two classes, and it would not do to have a third class. Having come to that conclusion, the Directors accordingly intended to issue perpetual debenture stock from time to time for the necessary purposes of the Company. They must make the issue a part of a very large sum, so that any subsequent debentures that they might issue would all rank alike. They must not have first, second, or third debentures. He would propose, and the Board had thoroughly considered the matter and also proposed, that they should create at once as large an amount of that debenture stock as their articles of association authorised. In their first issue they proposed only to raise enough money to pay off the existing debentures as they were entitled to. That was, a sum of £80,000. They would give gentlemen holding debentures the option—and many of them, he knew, would be only too glad to avail themselves of it—of taking their debentures, not in cash, but in exchange for other debentures of the Company. It would be better for them to be the holders of debentures in a large stock (which would be certainly quoted on the Stock Exchange, and greatly dealt in) than to be holders, as they now were, of a small issue of £75,000, for which there was neither sale nor power of purchase. Now they had to repay to capital account that £97,000 that they had spent up to the 31st October last, out of revenue, and he thought they ought to hold in hand a sufficient amount to carry them on to the end of their year, so that they should not be continually coming to them suggesting fresh capital. Fresh capital would have to be raised if their business went on, unless they made up their minds to relinquish it. They (the Board) thought the first issue ought to be something between £300,000 and £350,000.

He had now given them pretty nearly all the facts of their position, and the Board's view of that position was that it was a very favourable one, and that it gave, and ought to give, every shareholder great confidence in the future of that Company. At the same time the Board would be glad to listen to suggestions, and invited remarks from shareholders, so that any doubts might be removed and explanations made. There was no resolution to be proposed, and he would now sit down and hear what shareholders had to say.

Mr. Chipperfield asked that the list of towns linked together might be furnished to shareholders, and as to the present debentures.

The **Chairman** said the list should be circulated. The present debentures were perpetual stock, and amounted to £73,000; but the Company had the right of repaying these debentures at any time on payment of 10 per cent. premium; that was why he said it would take about £85,000 to clear them off. They paid 4½ per cent. interest on the present debentures. He could not say what they would pay on the new issue except that they would get them at as cheap a rate as possible.

Mr. Watson asked what injury was likely to occur to the Company from the expiry of the companies' patents.

The **Chairman** said the first result would be that all the world could use them. Up to the present they had had a practical monopoly. When the two patents were up everybody could interfere with them. But their policy had been to cover the ground—to be the man in possession. The bigger their business was, the less in proportion were the working expenses. What the result would be neither he nor anyone else could foresee. He had shown them that there were strong indications that the loss they suffered in the first instance by the reduction of rates, would be recouped by the accession of additional business. He could not prophesy more.

Mr. Watson asked if there was anything to oppose the Company now.

The **Chairman** said nothing except the company in Manchester, and they had had difficulty enough to get their money, and that was only £43,000.

Mr. Salter wanted to know if the through speaking lines to Manchester, etc., were likely turn out satisfactorily from a monetary point of view.

The **Chairman** said that in the main towns—Manchester, Liverpool, Glasgow and Bradford—and all towns of that kind, the reduction in rates had been from £15 to £10. In London they had made no reduction. In the provinces people paid for a radius of one mile from the exchange; some of them were not so far away. The radius in London was very much greater, and, in addition, the expenses were enormous. The wages there were double what they were in other places. That was a sufficient reason for the difference in rates between London and the provinces. Independently of that, he thought the main point in regard to London was not so much reduction of rates as increased efficiency. They had done a great deal in this way, but a good deal had yet to be done. Efficiency was the main thing in London, not reduction of rates. The amount of revenue they had derived from through lines up to the present was very small, but he was disposed to think that they would have to consider other ways of making these lines profitable. They had had enquiries from people having business connections in Liverpool and Manchester who wished to have a line to themselves, or the use of a line at certain hours. Others wanted to combine—two or three firms together—to have a line. Then, again, at night-time the papers wanted the lines. He was convinced that the working of these lines would grow. These remarks did not apply to the lines linking provincial towns together, from which they had a very large revenue.

Dr. Ellis asked if the existing poles carrying wires to Birmingham and Manchester were capable of carrying additional wires.

The **Chairman**: Certainly.

In answer to other questions the **Chairman** said their reserve fund was invested in their own business. He was not under the impression that a reduction of rates in London would bring a large accession of business, as Mr. Falke thought. The working expenses for the six months up to October came to exactly the same as last year—viz., 40 per cent. on the gross revenue. Last year the total crude income was £364,704. In the half-year ending April 30th, the income was £205,578. They had agreements with subscribers for periods of three, five, or seven years, as Mr. Biden suggested. They were on good terms with the Post Office. They were considering the question of obtaining a Bill giving them statutory powers to run their wires.

A hearty vote of thanks to the Chairman and Board was carried by acclamation on the motion of **Mr. Chipperfield.**

DIRECT UNITED STATES CABLE COMPANY.

The twenty-seventh ordinary general meeting of this Company was held on Friday, 16th inst., at Winchester House, Old Broad-street, Sir J. Pender, K.C.M.G., in the chair.

The **Chairman** said that the past year had been rather an eventful one, in some respects, commercially, both here and in America; at the same time he thought England had come out of it in a marvellously satisfactory manner. He hoped that the new departure which was being made in commerce would be largely beneficial to the telegraphic system. He would like to go back to the 5 per cent. dividends, but the only way to obtain them was by doing their work better, and by encouraging the development of the telegraphy between the old and the new world. The money that the Company was at present earning from the Atlantic traffic was about the same in amount as when the tariff was higher. Other companies now competed with them, and shared that traffic. The Company was doing its work wonderfully well, and was earning a fair amount of the traffic. There was a familiar saying that "a new broom sweeps clean." The Directors had to contend against these "new brooms," but he declared that experience could often bring about better results. The revenue for the past half-year, after deducting outpayments, was £43,347, and the working and other expenses amounted to £17,556, leaving a balance of £25,791. An interim dividend at the rate of 3s. 6d. per share for the quarter ending September 30 has been paid, and the Board recommended a similar distribution for the past three months, leaving £5,511 to be carried forward. The revenue for the half-year showed an increase of £990, equal to 2¼ per cent. over that of the corresponding period of 1889. He believed that telegraphy would never sleep, but would go on progressing. At the stations the expenditure had been £1,586 more, chiefly owing to their having now to bear the whole of the expenses of the New York office (instead of one-third only, as in 1889), and, secondly, to the prosecution of an active canvass for business on the Continent of Europe, as well as in the United Kingdom and New York and Boston. Their reserve fund, after being debited with £1,629 for the cost of repairs, and credited with £4,307 for interest on their investments, now stood at £252,678. The investments continued to be worth much more than their cost price, at which they appeared in the balance-sheet. The shareholders had receive the same dividend as had been paid to them for the last two or three years, and he would be very much disappointed if this rate were reduced. He moved the adoption of the report.

Mr. William Ford seconded the motion.

A brief discussion followed; and, in reply to Mr. Jackson, the **Chairman** reminded the shareholders that the litigation with the Compagnie Française du Télégraphe de Paris in New York was being conducted entirely by the Anglo-American company. The fact that this matter was not yet settled was not, however, the cause of their paying a dividend of 3½ per cent. instead of 5 per cent. The fact was that if they were paid according to the first prospectus which the Anglo-American company issued, the shareholders would now, he supposed, be receiving 200 or 300 per cent. They had, however, now to contend against science, codes, and competition between the different companies.

The motion was carried unanimously.

COMPANIES' REPORTS.

ANGLO-AMERICAN TELEGRAPH COMPANY.

The Directors of this Company recommend a balance dividend of 15s. per cent. upon the ordinary consolidated stock, and of £1. 10s. per cent. upon the preferred stock for the year ending December 31, 1890, both payable on January 31 next, less income tax, to the stockholders registered on the books of the Company on the 13th inst., leaving a balance of £44 to be carried forward. The above dividends, together with those already paid, will amount to £2. 17s. 6d. per cent. on the ordinary, and £5. 15s. per cent. on the preferred stock for the year 1890.

CITY NOTES.

Brazilian Telegraph Company.—The receipts for last week amounted to £6,099.

City and South London Railway.—The receipts for last week were £758, an increase of £10 over the preceding week.

The Commercial Cable Company announce that they have established offices at 8, Foster-square, Bradford, and 37, Albert-square, Dundee.

Notice of Removal.—The Fowler-Waring Cables Company, Limited, have transferred their London office to 4, Victoria-mansions, 32, Victoria-street, Westminster, S.W.

West India and Panama Telegraph Company.—The receipts for the half-month ended January 15 were £2,596 against £3,001; the September receipts, estimated at £4,789, realised £4,884.

Eastern and South African Telegraph Company.—This Company announce the payment by warrants on Feb. 2 of interest for the half-year ending Jan. 31 on their 4 per cent. mortgage debentures.

Western and Brazilian Telegraph Company.—The receipts for last week, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £4,935.

Eastern Telegraph Company.—This Company notify that the coupons on their 5 per cent. debentures, due Feb. 2, will be paid by Messrs. Glyn, Mills, Currie, and Co., 67, Lombard-street, E.C. Coupons should be left at the bank three clear days for examination.

NEW COMPANIES REGISTERED.

North-Eastern Telephone Company, Limited.—Registered by Waterlow Brothers and Layton, 24 and 25, Birchin-lane, E.C., with a capital of £4,600 in £1 shares. Object: to carry on the business of a telephone, telegraph, and electric light, heat and power supply company. There shall not be less than three nor more than five Directors. Qualification, £100. Remuneration to be determined in general meeting.

PROVISIONAL PATENTS, 1891.

JANUARY 12.

573. **Improvements in devices for hanging pictures, especially applicable to the casing of electrical conductors.** William James Rundle, Frank Benjamin Lea, and Anthony George New, 11, Furnival-street, London.

580. **Improvements in and relating to phonographs.** Frank Mitchell, 70, Chancery-lane, London.

584. **An improved construction of alternate-current dynamo electric motors.** Maurice Hautin and Maurice Leblanc, 28, Southampton-buildings, London.

587. **Improvements in or connected with incandescent electric lamps.** Frederic Harman Peter Berlyn, 23, Southampton-buildings, London.

593. **Improvements in electric primary batteries.** Theophilus Coad, 1, Quality-court, London.

JANUARY 13.

608. **Improvements in construction of channels for the use of electric conductors in streets.** Thomas Parker, Wolverhampton.

616. **An improved carbon stick or pencil for arc lamps.** Herbert John Allison, 52, Chancery-lane, London. (Barton Brewer Ward, United States.) (Complete specification.)

617. **Improvements in the construction of electric arc lamps, and appliances used therefor.** Herbert John Allison, 52, Chancery-lane, London. (Barton Brewer Ward, United States.) (Complete specification.)

624. **Improvements in electrical elevator apparatus.** American Elevator Company, 55, Chancery-lane, London. (Otis Brothers and Co., United States.) (Complete specification.)

641. **Improvements in electric clocks.** Emil Gustavus Hammer, 55, Chancery-lane, London. (Complete specification.)

647. **Improvements in electrical measuring instruments.** Henry Harris Lake, 45, Southampton-buildings, London. (Edward Weston, United States.) (Complete specification.)

649. **Improvements in and relating to electric elevators or lifts.** Henry Harris Lake, 45, Southampton-buildings, London. (Rudolf Eickemeyer, United States.) (Complete specification.)

650. **Improvements in electrical apparatus for indicating the progress and result of races, games, and the like.** Henry Harris Lake, 45, Southampton-buildings, London. (Samuel Dimmick Mott, United States.) (Complete specification.)

657. **Improvements in conduits for electric conductors.** Henry Harris Lake, 45, Southampton-buildings, London. (Arthur Lord, United States.) (Complete specification.)

667. **Improvements in electrodes for voltaic accumulators.** William Phillips Thompson, 6, Lord-street, Liverpool. The Hess Electric Storage Battery Company, United States.) (Complete specification.)

668. **Improvements in or appertaining to voltaic accumulators.** William Phillips Thompson, 6, Lord-street, Liverpool. (The Hess Electric Storage Battery Company, United States.) (Complete specification.)

669. **Improvements in electrical cut-outs or safety fuses.** Johann Puluj, 323, High Holborn, London. (Complete specification.)

675. **A new or improved electric regulator.** Royal Edward Ball, Norfolk House, Norfolk-street, London. (Complete specification.)

JANUARY 15.

743. **Improvements in the application of electricity for mining purposes.** Walter Osmond Rooper, 23, Greengate-street, Stafford.

JANUARY 16.

846. **Improvements in electrical cables.** Walter Victor Morten, 2, Lithos-road, South Hampstead, London.

JANUARY 17.

860. **An electric bell repeater. An electric bell and receiver for electric signals.** Arthur Henry Bagnold, Borstal Cottage, Rochester.

861. **Improvements in the insulation of metals for electrical purposes.** George Lee Anders and Charles Herbert Elliot, 10, Bush-lane, London.

871. **Improvements in telephone transmitters.** James Frederick Bennett and Ernest Parker Hides, Howard Villas, Rupert-road, Nether Edge, Sheffield.

884. **Improved apparatus for the production of electricity.** Charles Wells, 22, Southampton-buildings, London.

889. **Apparatus for manufacturing corrugated lead boxes for electric accumulators.** Woodhouse and Rawson United, Limited, 28, Southampton-buildings, London. (Thomas Knight Steanes, Australia.)

899. **Improvement in electric cells or batteries.** Henry Thomas Eager and Richard Philip Milburn, 433, Strand, London.

908. **Improvements in insulators for electric wires.** Frank Atherton Ross, 53, Chancery-lane, London. (Complete specification.)

910. **Electromagnetic mechanism for controlling the transmission of power.** Alexander Melville Clark, 53, Chancery-lane, London. (Washington H. Kilbourn, United States.)

SPECIFICATIONS PUBLISHED.

1884.

10990. **Telephony.** Langdon-Davies. 8d. (Second edition.)

1886.

16616. **Telegraphy.** Langdon-Davies. 11d. (Second edition.)

1889.

20974. **Electric supply.** Van Rysselberghe. 8d.

1890.

135. **Alternate-current motors.** Atkinson. 8d.

1246. **Electrolytic generation of chlorine, etc.** FitzGerald and Falconer. 4d.

NOTES.

Dorking.—The authorities are expected to take practical steps for the immediate introduction of the electric light.

Cambridge.—Dr. Fleming is busy deciding upon the details of the scheme of electric lighting for Cambridge. The system so successfully employed at the Berlin central stations is in favour.

Chili Cables.—Owing to the revolt in Chili, telegraphic communication by the Mexican West Coast cable is interrupted south of La Serena. The Valparaiso cable stopped operations on Jan. 22.

Stephen Gray.—In the *New York Herald* appears an interesting article on the veteran electrician, Stephen Gray, who even before Franklin determined that electricity and *lightning* are identical.

The Edinburgh Exhibition.—It has been arranged that a first dividend of 12s. 6d. in the pound shall be paid by the liquidator to the creditors of the recent Edinburgh International Exhibition.

Death.—A Reuter telegram from Rio de Janeiro announces the death of M. Benjamin Constant, Minister of Public Instruction, Posts and Telegraphs, and ex-Minister of War in Brazil.

Mr. Drake's Accident.—Mr. Drake has sufficiently recovered from his severe accident to enable him to be conveyed home from the Westminster Hospital, and it is hoped that he will in time thoroughly recover from the effects of his fall.

Odessa Telegraphs.—Long sections of the telegraph lines in South Russia ending at Odessa have broken by the unusual prevalence of dense fogs which have frozen on the lines and weighed them down. Several cases of freezing to death of the linesmen are reported.

Lane Fox Patents.—An agreement has been entered into between the Lane Fox Electrical Co., Ltd., and the St. James and Pall Mall Electric Light Company, whereby the St. James Co. take a license to work under the Lane Fox distribution patents and pay a royalty to the Lane Fox Co.

Electrical Pocket-Book.—Prof. S. P. Thompson is bringing out an electrical engineers' pocket-book—a tiny little *vade mecum* actually capable of going into a waistcoat pocket, and filled with just that sort of practical information, figures, and references that are wanted on the spur of the moment in actual work.

Maxim-Weston Plant.—Messrs. W. R. Pryke and Co., hardware merchants, of 48, Upper Thames-street, E.C., have completed arrangements for the purchase of the valuable plant, machinery, and stock, formerly the property of the Maxim-Weston Electric Co., Ltd., at their extensive works, Kingsland-green, London, N.E.

Exhibition at St. Pancras.—The clerk of the Vestry of St. Pancras has presented a report to the Electric Light Committee with reference to the subject of holding an exhibition of electrical appliances at the Vestry Hall for the ratepayers' information. The committee has approved of this idea and the exhibition is to be held shortly.

The Electric Motor Business.—The Edison Company of Boston, U.S., is at present furnishing current for 504 electric motors having a total capacity of 1,450 h.p. These are run on a 220-volt circuit. During the past month contracts for 72 h.p. have been closed, and the average for the past 18 months has been 50 h.p.

Christmas Tree at the Foundling Hospital.—Mr. Pitkin, of Red Lion-street, is lighting up the annual Christmas tree at the Foundling Hospital yesterday and this evening. There are 100 8-volt lamps, run a set of portable accumulators. These are slightly over-incandesced, and the effect is thus obtained of a number of stars, a very surprising and pleasing effect for the amusement and pleasure of the children.

Insulated Wire Works.—We have received samples of lead-covered cables for electric light, and also for telephone purposes, from the British Insulated Wire Company, made under the patents of the Norwich Insulated Wire Company, of New York. Works are being constructed on 10 acres of land communicating with the London and North-Western Railway at Prescot Station, Lancashire. These works are to be finished by the end of the year.

King's College.—An appeal is being made for the sum of £50,000 to enable the council of this college to meet the increasing demands of education, particularly in regard to modern science and experimental research. The council have received several liberal gifts and promises, amongst them one from Lady Siemens of £6,000 for the establishment of an electrical laboratory. Donations to the King's College extension fund may be made to Messrs. Coutts and Co., or to the secretary.

New Cable.—A Reuter's telegram, dated Washington, Jan. 28, says: Mr. Mitchell introduced a Bill in the Senate yesterday sanctioning the incorporation of a Pacific Railway Cable Company, with a capital of 5,000,000dols., which would work a cable between San Francisco, Hawaii, Samoa, and Japan. The Bill provides that the majority of the directors shall be citizens of the United States, and authorises the Treasury to pay the company an annual subsidy of 200,000dols. for 15 years.

Transmission of Power in Spain.—An installation for transmission of force, the first on a practical scale in Spain, was inaugurated a few days ago at San Juân las Fonts, in the province of Gerona. A paper mill receives 50 h.p. transmitted a distance of nearly a mile. The dynamos are driven by turbines, and the current is conducted along bare copper wires of 8 mm. diameter, suspended on porcelain insulators mounted on ordinary telegraph posts. All the material are made by Messrs. Planas, Flaguer, et Cie., of Gerona.

French and German Government Cables.—The following rather important item of news is given in the *Electrical World*: "The Standard Underground Cable Company, of Pittsburgh, has secured a contract from the French Government for the erection of a plant with which to manufacture the underground cables for that republic. A. J. Waring will sail for Paris to begin at once the work. The French Government has determined to bury all the wires under its control. The plant which the Pittsburgh concern is to build will turn out about a million and a half dollars worth of cable wire yearly. The same corporation is negotiating for the erection of similar works in Berlin."

O.S.A. Conversazione.—On Saturday, January 24, a most enjoyable evening was spent at Prof. Perry's house, 31, Brunswick-square, Mrs. Perry having kindly invited the members of the Old Students' Association of the City and Guilds of London Institute to an "At Home." A very excellent programme of music was provided—violins, Mr. Gatehouse and Miss Doughty; 'cello, Mr. Roger Bucknall; vocalists, Miss Cherry and Mr. Howden Tingey; accompanyists, Mr. C. G. Lamb and Miss Doughty. In all there were about 200 persons present, most of whom were students and their friends, but in addition to these there were several distinguished electrical and scientific men, amongst whom we may mention Profs. Ayrton and Meldola, and W. H. Preece, Esq.

A Permanent Electrical Museum.—Two years ago in Prof. Flowers's presidential address before the British Association, great stress was laid upon the advantages and upon the need of organisation of museums. We took the opportunity, in our issue of September 13, 1889, to advocate the necessity for the establishment of a permanent museum for the electrical profession in conjunction with the present Institution of Electrical Engineers. We are given to understand that now the Institution has had to remove its quarters from its old *habitat* to Victoria-mansions, the possibility of some action in this direction is contemplated, and that the matter will be brought before the Institute, and we are pleased to see our contemporary, *Electric Plant*, in a forward proof kindly sent to us for remark, is actively advocating the same proposal.

Bath.—We are glad to learn that considerable and gratifying improvements have taken place at the Bath central station. The festoons of wire and other temporary arrangements that made this station look somewhat like a Yankee station have given place to the neatness and solidity that should distinguish English engineering work. The high-potential terminals also—previously a source of our complaints—are now covered in with glass and out of harm's way, and matters have smoothed over considerably since the new chief engineer took up his work there. The supply of current has been remarkably steady and regular. The Bath authorities charge a fine of some shillings for every extinction of lamps, yet in last quarter's account only 8s. was deducted on this account, while during this period some 60 of the gas lamps yet in use were out.

Electric Light in Irish Railway Carriages.—The Great Northern Railway Company of Ireland have lighted up one of the trains by electric light, and the results of the trial of the morning mail from Dublin to Drogheda are very satisfactory and justify extension. The arrangements were carried out by the Electrical Engineering Company, of 61, Dawson-street, Dublin. There are 18 accumulators, and four 5-c.p. lamps in the first-class carriages, with very handsome fittings. All lamps except one can be turned off at will. There are two lamps in the second classes. The cells supply current for 10 hours at 35 volts. A Brush engine and Stockport gas engine are being erected to charge the cells for further experiments with the mail trains, and arrangements will be made for charging by means of the dynamo on the train if the scheme is carried through.

Brighton.—The work upon the central station at Brighton is being pushed forward rapidly. Already the roof is on the building. The Goolden dynamos were tested last week at Messrs. Willans and Robinson's, and gave extremely good results. The conditions stipulated a rise in temperature of not more than 60deg. F. after a run of 12 hours. The tests showed an efficiency from engine to dynamo of 85 to 86 per cent. on a 75-h.p. engine. The temperature was only 20 per cent. on the fields and 60deg. on the armature after seven hours' run, and steady at this temperature. The laying of the mains at Brighton is in the hands of the Callender Company, and work is actively commenced. Special means of connecting and disconnecting the feeders and branch mains anywhere in the network are here adopted, as will be described in our articles on these mains, commencing this week.

Vaughan-Sherrin at the Cycle Show.—Mr. Vaughan-Sherrin has got his foot into the cycling world, and may be expected to astonish both users and manufacturers. One of his electric Bath chairs are on view at the Stanley Cycle Show at the Crystal Palace, and is creating a good deal of interest. It may be remembered we described a test journey with an old Bath chair, fitted up with one of Mr. Vaughan-Sherrin's motors and batteries, which went well and easily. A well got up specimen of this electric Bath chair is shown amongst the other novelties of the cycling season. The smallness and lightness of the battery required to supply power is the principal feature, the weight of the two troughs of cells required to drive the chair and its occupant five miles an hour for eight or nine hours being only 100lb. The application to an actual tricycle is also shown.

Glasgow Telephones.—Complaint is being made at Glasgow that whereas subscribers engage to pay £10 a year for five years to the National Telephone Company, and have to continue payment even if disconnected before that time, yet the company are exempt from responsibility if the service is not kept up. At a meeting at the Corn Exchange it was explained that a great number of members of the trade had subscribed to the Mutual Telephone Company, whose system is expected to be completed and in working order in the course of two or three months, and which is represented to give a more efficient service at £5 per annum within the one mile radius, or half the reduced rate of the National Telephone Company. Those whose contracts were expiring with the old company were warned not to commit themselves for more than one year. It was resolved that the meeting support the new company.

The London and Paris Telephone. — As telephonic communication is to be opened between London and Paris early in March, M. Jules Roche, Minister of Commerce, it is stated, is at present engaged in drawing up the conditions for the working of the service. The Minister is also occupied with the draft of a convention with the British authorities, of which the following would be the essential points. The charge for the use of the telephone would be 10 francs for a three minutes' conversation. This charge would at first be only experimental, and might be reduced should experience render such a step advisable. The telephone might be used at any time, day or night. The correspondents of the two nations would be granted alternately the privilege of availing themselves of the new means of communication. The British authorities, on their part, will adopt such measures as they may deem fit.

Electrical Examinations.—The manager of the School of Electrical Engineering, Mr. L. Drugman, informs us that as the result of recent examinations the following students have now obtained the vellum certificate of the school. (*a*) In electric lighting and power transmission: Messrs. A. C. D. Crommelin, B.A., J. Finlay, J. F. Irgens, H. Macfarlane, L. Marchetti, F. J. Moffett, B.A., R. J. F. Mostyn, J. W. Parr, P. F. W. Simon, P. J. S. Tiddeman, H. Treherne, L. W. Wild, C. B. Wigg. All these students belonged to the advanced class (instructor, Mr. Charles Capito, M.I.M.E., M.I.E.E.). This examination was conducted by Mr. Gisbert Kapp, M.I.C.E., M.I.E.E., and consisted of a paper in mechanical engineering, a paper in electrical engineering, a *viva voce* and practical examination, and drawing. (*b*) In telegraphy and telephony, Mr. H. Treherne, above named. This examination was conducted by Mr. H. R. Kempe, A.M.I.C.E., M.I.E.E., of the Engineer-in-Chief's office, General Post Office.

The City Commission of Sewers.—At a meeting of the City Commission of Sewers held on Tuesday at Guildhall, the Commission resolved that a petition be presented to provide, in regard to the London Overhead Wires Bill, against any alterations being made therein prejudicial to the jurisdiction of the local authority. On the question of presenting petitions against the Central London Railway and the City and South London Railway (Islington Extension) Bills, to enable the Commission to offer such opposition as might be deemed expedient, Mr. A. A. Wood said the two underground lines would cross beneath the roadway in front of the Mansion House, and there was this radical defect, that the tubes of the two companies were of different sizes, so that if the exigencies of the traffic should eventually require it, there would be no possibility of linking the two lines together. The Court resolved to petition against the Bills, with a view to obtain *locus standi* to insert amendments should the necessities of the case thereafter require it.

Showroom Fittings.—Some little difficulty and trouble is generally experienced in arranging the connection of electroliers and pendants in showrooms. Often a large number are shown, and are desired to be so arranged as to give the possibility of lighting any pendant to show to visitors. This necessitates, when fittings are taken down or changed, much screwing and fitting of connections. Now, the best and simplest way for fittings in showrooms is evidently that employed for transportable fittings generally—namely, with wall sockets. Accordingly, in one of the best-known electrical showrooms the system is employed of running many circuits on the ceiling, each circuit fitted with several wall sockets, and alongside each wall socket an ordinary brass hook. This hook takes the weight of the electrolier, and any electrolier or pendant can be hung up, taken down, altered in position, and nevertheless be lighted at once by this use of abundant wall sockets on the ceiling instead of ceiling roses. The saving of trouble and gain in ease make this simple system worthy of being employed in electrical fitting showrooms.

The Reform of Science Teaching.—The reform in the methods of science teaching in schools and colleges, in aid of which we have attempted to throw what influence we have in the department of electrical engineering science, seems to be also a matter of considerable discussion at this instant in France, between two members of the Academie des Sciences (and also of the Academie Française), M. de Freycinet, Minister of War, and M. Joseph Bertrand, classical mathematician. The point of discussion is the reform in the system of examinations, especially of the matriculation of the Ecole Polytechnique. The examinations, it is maintained, are a quarter of a century behind the times, surcharged with a mass of antiquated accessories, tending to stifle the minds of the students to real learning and develop simply a false vivacity in cramming useless and merely gymnastic exercises—memory being substituted for reflection and true grasp of the subjects taught. We wish the reformers every success in their crusade, which is doubtless as much needed the other as it certainly is this side of the Channel.

Proposed Extension of the Electric Subway.—A movement is on foot among some influential residents of Peckham and East Dulwich with the object of obtaining an extension to those districts of the electric railway recently opened between King William-street, City, and Stockwell. A largely-signed memorial of the inhabitants has been drawn up, praying the local authorities to increase the railway accommodation of the district, which, it is complained, is at present far from satisfactory; and the Camberwell Vestry officials will shortly approach the directors of the new electric company with regard to the matter. Should the company entertain the proposed scheme, it is suggested that their system should be extended from the Elephant and Castle, through the Walworth-road, on to Camberwell-green, and thence down the Peckham-road to East Dulwich and Nunhead. At present the trains of the London and Brighton Company from East Dulwich to the City go only to the south side of London Bridge, an arrangement by which much inconvenience is said to be caused in bad weather to travellers to the metropolis.

Visiting Deputation from Manchester.—The Manchester City Council are still undetermined whether to undertake the electric lighting itself or to advertise for tenders. In order better to arrive at a decision, a sub-committee has been appointed to visit a number of towns where central electric light stations are to be seen. This practice of recommending visits of deputations to towns already lighted is becoming quite common amongst corporations, and commends itself from the point of view of the dsirability of committee men obtaining practical knowledge at first hand. It is to be wished, however, that the committee before actually setting out upon their visit will take such steps as will enable their report to be a really useful, important, and enlightening one. The advice or co-operation of a competent technical engineer, combined with the business capacities of the committee, ought to bring forth much most useful information upon the status and prospects of various systems as applied to various towns, which would then more than justify the Corporation in their expenditure of time, money, and energy in visits to the electrically-lighted towns of England.

University College.—An appeal is being made for a sum of £50,000 for University College. The further funds are needed to provide for the teaching of new subjects, for the extension of buildings, for new teaching appliances which are rendered necessary by the advance of knowledge and improvement of educational methods, and for the better payment of teachers. The chief purposes for which money is now required are: 1. A new laboratory for the teaching of experimental physics. 2. Increased accommodation, apparatus, and machinery for teaching electrical engineering. 3. Increased accommodation and appliances for teaching mechanical engineering. 4. A collection of architectural models and accommodation for a school of architectural drawing. 5. Additional laboratory accommodation and apparatus for the work of supplementing the lectures of the Society for the Extension of University Teaching. 6. Further endowment of teaching, especially in the department of modern and Oriental languages. A committee has been formed, with power to add to its number, to appeal for funds for the above purposes, and the names of members of the committee, with a first list of subscriptions, will shortly be published.

Electric Fire Alarms.—A most suggestive piece of information is given in the annual report of the Glasgow Fire Brigade, which states that the damage done by fires attended by the brigade during the year just closed amounted to £43,500, as compared with £150,000 in 1889 and £206,000. Whence this sudden diminution, it may well be asked. The firemaster states: "Although several important buildings have been jeopardised during the year through the occurrence of fire in them, he is pleased to state that serious loss has in no instance resulted, this being in a large measure due to the early discovery of the outbreaks, and the speedy means of communicating with the brigade offered by the electric street fire alarms, which were used to intimate 200 fires last year," out of a total of 425 attended by the brigade. A result so striking is well worthy of being used as a lever to corporations by electrical firms capable of carrying out contracts for electric street fire alarms. The Edinburgh authorities are already being urged to adopt the system so successfully introduced by the sister town.

The objection of "malicious calls" is the one most urged, in answer to which it may be stated that out of a total of 500 calls in Glasgow, 29 only were "malicious," while the probable saving to the town was some £200,000.

Church's Slide Valve.—Two great industries are struggling for the method of making the production of power by steam engines more and more economical. These are the marine and the electrical industries. No other industries require constantly and usually such aggregations of engines of immense power. At present, except in one case not yet started, the marine engines are the larger, and have led the way in progress of economy of production. We are able to announce the very practical result just achieved by the adoption of a new type of slide valve, known as the Church's slide valve. Usually the slide valves of an engine act as a veritable break upon the engine, being pressed against the metal slides with the force of very nearly the whole steam pressure, 100lb., 120lb., or 160lb. per square inch. In Mr. Church's valve this pressure, by an ingenious application of simple principles, is almost entirely taken off. The result is best stated by the fact that one of the steamship companies have had these valves applied to one of their steamers, and while doing the voyage in less time, 390 tons of coal less were consumed on the voyage, representing a saving of some thousands of pounds a year, due entirely to the introduction of this valve. The principle upon which the new slide works is briefly this: that as at present used the steam presses the valve to the slide with full force of steam pressure; by making the slide in two parts, fitted together telescopically and admitting steam to the inner part of the slide valve, the steam is ingeniously made to press equally on all sides, and all strain is consequently taken off the slide valve itself, so much so that it is necessary to put in a spring to press the valve against the portholes. We understand that so satisfied are the company with the result that other ships are being fitted, and that Blairs, the well-known shipbuilders, have taken out a license, and will fit the Church slide valves to all ships now built. The invention should be equally useful for large electric central station engines.

Automatic Insulation Tester.—A new instrument has been invented, for which we prophesy immediate and extended usefulness as soon as it is put on the market. Before describing it let us just recall the conditions on an ordinary large private or other installation. The wiring is done by the best firm, we will suppose, by good men under good superintendents, with the best wire on the best Phœnix principles. The insulation is tested, and the tests show the best results—insulation so many megohms. The installation is passed, lamps are lighted, and all goes well—for a time. This time may be long or may be short, but accidents will happen, and deteriorations will occur, and sooner or latter a leakage may—we do not say must, but may—occur. There is usually no test, no warning of this. You do your best and then—trust to Providence. Now, in a central station, and more so still in an important installation, where technical men are not always about, it should be possible to have an immediate warning at the slightest giving way of the insulation. That is, at the first occurrence of a partial short circuit an indication should be given. Mr. Reginald J. Jones has invented a very simple little piece of automatic apparatus for this purpose, an adaptation of an easy test. Taking two lamps run in series (50-volt lamps for a 100-volt circuit) across the mains, the current through them, and therefore the brightness, will be the same in each. Connect the wire between the lamps to earth, and on the slightest leakage on either positive or negative wire one of the lamps will receive more current, and will therefore glow brighter. This will indicate to the eye of the attendant the commencement of danger. A polarised relay, starting an electric bell, will indicate the incipient danger to his ear. An American clock, moving contact hands, causes the instrument to be connected twice or several times in the hour, so that the state of the installation mains are constantly kept under test. Where thousands of pounds are in hazard the addition in large installations of this ingenious little time tester will be a welcome safeguard indeed.

Development of Bradford Central Station.—Extensions of considerable magnitude have been made at the Corporation electric works at Bradford, chief among which are a large set of Crompton-Howell accumulators. This addition was inaugurated last Tuesday by Alderman Priestman. When he arrived at the works one of the engines had been started, and was supplying the town. Alderman Priestman turned on the main battery switch, and gave instructions for the engine to be stopped. This was done, and the batteries solely supplied the current needful for the lamps then on, which, according to the indicators, were equivalent to 250 of 16 c.p. each. The whole battery contains 65 cells, of which 58 were then necessary to send the requisite pressure to the terminals of the lamps in the town. Later in the day as the output increased, more cells were switched on, thus maintaining a constant potential at the feeding centres. The accumulators will be able to supply 2,000 lamps of 16 c.p. each for an hour. The cells are each 5ft. 6in. long, 12in. broad, and 12in. deep. Each cell contains 67 lead plates 8½in. square and ⅜in. thick. The batteries will not be fully developed for some little time, as it is necessary to allow the plates to form. The charging is only by a Willans engine of 150 h.p., the charging current being 170 amperes. The trial of the accumulators was thoroughly successful. In transferring the lighting from the engine to the batteries no fluctuation whatever was discernible. There has been added to the plant at the works a Willans engine of 300 i.h.p., and working at a pressure of 140lb. to the square inch. This engine drives a dynamo capable of supplying 250 lamps of 16 c.p., by Messrs. Siemens Bros. It is the largest of its class turned out by this firm, and is one of the finest machines they have made. The total horse-power represented now at the station is about 800, there being, in addition to the engine in question, three of about 150 i.h.p. each. Since the beginning of November three new feeding mains have been put down in the town, but perhaps the best way of indicating the growth of the installation will be to say that when the works were opened in September, 1889, there were connected with them lamps of a total power equal to 800 candles only, whilst there are now lamps supplied representing 120,000 c.p.

Frankfort Exhibition.—The utmost efforts are being made by the executive committee of the Frankfort Exhibition to cause the eyes of all Europe, and especially all scientific Europe, to turn towards them as they did two years ago to Paris. The greatest possible employment will be made of the newest advances of electrical science. In the railway section there will be four model systems of electric railways. The three distinct systems will be represented—overhead conductors, underground conductors, and accumulator traction. The telephone section will include the original instruments designed by Reiss, the unfortunate professor who first realised this world-famous invention. The telephonic section will be put into communication with the concert-halls of Frankfort, Wiesbaden, and Munich. There will be printing and typewriting machines in communication with the central station, and automatic telephones will also be shown. A large section is devoted to electro-chemistry. Amongst electrical laboratory apparatus will be the "resonators" of Prof. Hertz. In the machinery hall there will appear 20 systems of dynamos and 40 kinds of engines, the total force being 3,900 h.p. Amongst the practical experiments in electrical transmission of power, which are to form such a noticeable feature of this exhibition, will be the transmission of 100 h.p. from the Frankfort Jardin des Plantes, where the generating station will be seen, and 100 h.p. from Offenbach, and, most striking of all—a standing demonstration to the world—the transmission of 300 h.p. from Lauffen-sur-Necker, a distance of 300 miles. This last will only be carried out if the Telegraph Department gives the consent which has been officially asked. There will be six batteries of accumulators, capable of supplying a current of 400 e.h.p. for several hours. Messrs. Siemens Bros. have constructed a cable destined to carry a current at 20,000 volts. In various workshops motors will be employed up to 75 h.p., and the most varied work will be accomplished by this means. Various experiments will be made on different kinds of transformers, and upon the transmission of force by discontinuous currents. What more particularly will render the exhibition of extreme interest to electrical engineers and the world in general, will be that all the machinery shown will be subjected to carefully made tests, and the results of these tests will be fully published.

Architectural and Enriched Casings.—We have been waiting a long time for the book we have now before us, not knowing when or by whom it would be written. Designs useful, and to a certain extent ornamental, of electric wire casings we have seen from several well-known makers. But a really high-class set of designs of ornamental mouldings specially adapted for interior use in artistically decorated houses we are only just able to acknowledge in the shape of "Architectural and Enriched Casings for Electric Wires," by F. A. Fawkes, of Chelmsford, author of "Architect's Joinery and Its Ornament," published by B. T. Batsford, 52, High Holborn, London; price 2s. 6d. The author, who has evidently made a careful, even a loving study of the art of designing mouldings, mentions he has been applied to at various times for the designs of electric wire casings. He has embodied the best of these designs in the book now published, which is believed to be the first attempt made to systematically introduce architectural skirtings, dado rails, picture rails, and cornices, with grooves and portable covers for carrying electric wires. The designs are of a high order of artistic merit, embodying both severe and decorative treatment of mouldings. Full-sized sections of some 40 specimens of plain casings, with sections of plain and enriched picture and dado rails and cornices are given, while for the more decorative mouldings to assist engineers and architects in the selection, photographs taken from actual specimens are added. We have nothing but praise for this book, which deserves to be in constant use by electrical engineers who have to fit good houses. Some special points in these mouldings are to be noticed—the enrichments are glued upon the wood covers and are made from specially tough composition, not liable to chip or crack like plaster, and when set will take a clean saw cut. The grooves on these casings are made parabolic, a shape taken as offering special advantages for retaining the conductors in place when pressed into the grooves, while also allowing a certain amount of play for inequalities in the insulation. For this suggestion, which certainly seems a useful one, the author is indebted to W. A. Chamen, Esq. A further point is that the covers to the mouldings are all made of sufficient thickness to prevent curling, a too common fault with casing covers hitherto employed. It must be noticed that all these electric casing designs of Mr. Fawkes are protected against infringement.

Great Snowstorm in America.—The fearful snowstorm which prevailed along the Atlantic coast last Saturday night and Sunday morning rendered New York almost helpless. The fall of snow was very heavy, while a high wind prevailed, driving it into high drifts and impeding the traffic in the streets, which, in fact, was for hours completely suspended. All the electric light and telephone wires are down, and the night after the storm not an electric light dependent upon supply companies was burning in the city. The police warned citizens to exercise extra vigilance, as the police and fire telegraphic wires were down, and no alarm could be given in case of fire. The damage in New York alone will cost several millions of dollars to repair, and the injury done in the vicinity must be very great. The city and surrounding country, according to the telegrams, present a scene of desolation in consequence of the storm that is difficult to describe. In the lower part of New York, where the old-fashioned telegraph poles were still standing, the streets are blocked with a number of prostrate poles and miles of entangled wires. Business has been practically at a standstill all day, for all the merchants and brokers have been almost entirely cut off from communication with the outside world. The telegraph companies are the heaviest losers by the storm, as it is estimated that the damage done to the various lines will reach at least half a million dollars. Fifteen hundred wires are rendered completely useless, and it will require at least two weeks to put them in working order again. At the present moment only two telegraph wires are working out of New York, one to Chicago and the other to Albany. All the newspaper and commercial and private wires are down, and the local newspapers appeared this afternoon again with nothing but European news in the matter of telegraphic information, and very little of that. Telephonic communication is almost cut off, as nearly every telephone wire in the city is down or injured. It is estimated that 2,500 of these wires are destroyed, and that the damage to the telephone company will amount to at least 150,000dols. It will take a week or 10 days to put the telephones in working order again. Traffic is almost at a standstill, the snow and subsequent rain, followed by a sharp frost, having made the streets impassable. Telegraphic communication was subsequently restored between Boston and New York, *viâ* Hartford, and the Atlantic cables are working slowly, but improvingly. Further intelligence received of the damage caused, tells that the Western Union Telegraph Company at 10 o'clock that night had 15 wires working to the westward, but possessed no direct communication with the south. They expected to be able to clear off all the business on hand before daylight. The telegraph service in New Jersey and Long Island remain paralysed, but all the submarine cables are working satisfactorily. The snow at Wilkesbarre and in the surrounding districts has been very heavy, causing much damage to the telegraph wires. At Lancaster, in the same State, many of the wires blown down crossed each other and flashes of fire ran along the streets following the broken wires, great alarm being thus caused. A telephone despatch from Harrisburg states that, with a single exception, all the wires connected with that town are down. According to mail advices from Philadelphia, the telegraph service there is entirely crippled. The storm was especially severe between Philadelphia and Harrisburg, great numbers of poles being brought down. Much time will be required to repair the damage done.

DYNAMOS: THE CONSIDERATION OF THE CHIEF FEATURES WHICH REGULATE THEIR APPLICATION.*

BY MR. A. B. BLACKBURN, A.M.I.C.E.,

Assist. Manager, Messrs. Mather & Platt's Electrical Department.

The continuous-current dynamo, which can alone engage attention to-night, consists in its most usual form of a fixed magnet and a rotating armature, separated by a narrow air space. Under the influence of the magnet, the air space between the polar surfaces and the armature core experiences a change of condition, which constitutes what is known as a magnetic field, and the whole activity of the machine is centred in the armature conductors as they revolve in this field. A difference of electrical pressure is constantly maintained along their length, and when their ends are connected through the brushes to the external circuit, so as to form a closed system, a current of electricity is established. The pressure is proportional to the strength of field and to the rate at which the conductors cut it.

If iron filings be sprinkled on a surface placed in front of a magnet, they arrange themselves in lines, having definite directions and more or less densely distributed, in different parts of the field, Fig. 1, whence Faraday derived the conception of defining its strength as proportional to the lines contained in a given area. In a dynamo the field is produced by means of an electromagnet, the construction of which will be familiar to all. The current round the magnet is said to induce the lines of force, or to give rise to an induction, and these lines in turn induce a current in the moving conductors.

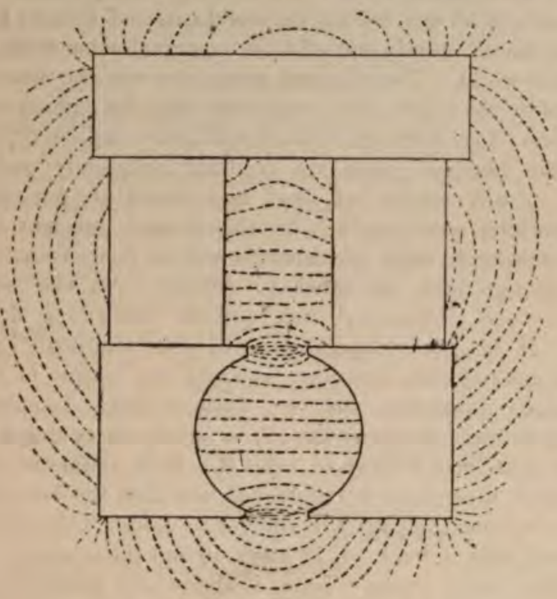

Fig. 1.

The effect which a magnet has on a compass needle, and the powerful way in which it attracts iron from a distance, are well marked evidences that the induction can be transmitted across space, and it is impossible to resist the conclusion, that this can only occur through the agency of a strain of some sort, produced in the intervening medium or dielectric, following the course of a closed circuit running through the iron and crossing from pole to pole, as delineated by the lines of force. Now, a field identical in its properties with this magnetic field, surrounds every conductor along which an electric current is flowing, the lines of force being circular, with the conductor threaded through them. Such a field is essential for the propagation of current, and whatever affects the strength of one also affects the other, consequently, by interlinking a magnetic with a conducting circuit, as is done in a dynamo, and giving them a relative movement so as to vary the number of lines enclosed, a displacement takes place which is in the nature of a flux. The field owes its properties to the dielectric being able to withstand the application of the stress, but in the conductor, as its name implies, the field breaks down, and the power, which has to be continually supplied to build it up again as the conductor moves into a fresh position through the field, is conducted away, to reappear as current energy in the circuit, where it can be either reconverted into mechanical energy by acting on another magnetic field, stored up as latent chemical energy, or dissipated in light and heat.

The effect may be popularly likened to that of a pump employed to circulate water in a closed system of pipes, and it is no more necessary to suppose that the dynamo creates electricity than that the pump creates water. The electricity may be regarded as lying dormant in the system until set in motion by the pressure generated in the revolving armature, when it makes its presence felt by giving rise to what we call an electric current. In the pump, work is done in lifting the water against an opposing head and in overcoming friction, and the measure of the work done in a given time, is the product of the head of water into the quantity. In the dynamo, work has to be done in order to drive current through the circuit against the opposing pressure or resistance, and the rate at which it is done is measured by the product of the pressure into the current. The unit employed for reckoning the pressure is called the volt, and for the current the ampere, and for their product the watt, of which 746 are equal to 1 h.p. The other quantity with which we are concerned is the resistance, which is the name employed to express the opposition to the passage of the current, offered in greater or less degree by all substances; its unit is called the ohm. The product of resistance into current is equal to the pressure, so that loss of pressure, due to resistance between any two points in the circuit, is proportional to the current flowing:

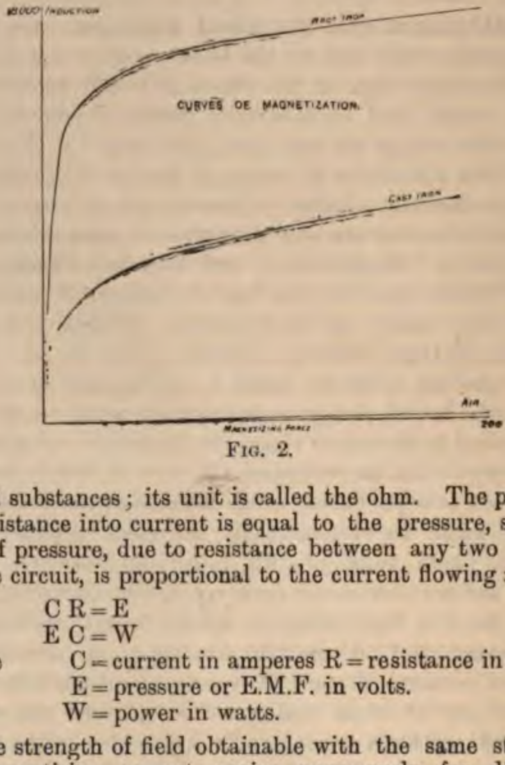

Fig. 2.

$C R = E$
$E C = W$
where C = current in amperes R = resistance in ohms.
E = pressure or E.M.F. in volts.
W = power in watts.

The strength of field obtainable with the same strength of magnetising current varies enormously for different substances. This is expressed by saying that their permeability to the lines of force is different. The permeability of air may be taken as unity, and is independent of the intensity of the magnetising force. In soft iron, with very high magnetising force, the induction may be pushed to over 30,000 lines per square centimetre, but, as shown in the curve, Fig. 2, where the relation between magnetising force and induction is plotted, there is a falling off in the permeability as the magnetisation increases. In iron it is probable that every molecule is already a magnet, but as far as external action is concerned, the resultant force is nil, which Prof. Ewing has recently shown there is reason to believe, is because the molecules under their mutual attractions form groups, in each of which the magnetic circuit is closed on itself. When, however, the iron is subjected to a magnetising force, such as is produced by passing an electric current round it, these groups are broken up, and the molecules tend to set with their axes parallel, so as to form a continuous magnetic circuit through the whole length, with poles at the bounding surfaces of the extremities. The rotation of the molecules is not, however, proportionate to the strength of the current, and to make them assume their ultimate positions, with poles at right angles to its direction, would require an enormously strong current, hence the falling off in permeability.

---

* Paper read before the Manchester Association of Engineers

If the path traversed by the lines of force for the whole of their length was through air, as would be the case with coils enclosing no iron, their number would be enormously reduced, and they would be scattered. The coils necessarily take up a good deal of room, so the length of the magnetic circuit has to be considerable, but with iron present, the force is handed on with nearly as full intensity as if all the coils were packed into a thin belt close to the armature, and the length of the circuit proportionately reduced; so that in the dynamo the part performed by the iron is one of concentration.

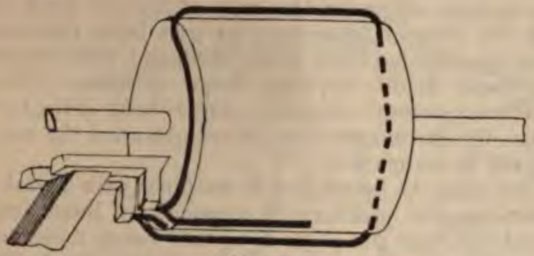

FIG. 3.

All armatures are built on one or other of two fundamental types, the drum, Fig. 3, in which the conductors are all wound externally, and the ring, Fig. 4, in which they envelop both inside and outside of the iron core. As the connections for each are analogous, it will suffice in tracing the action to select the ring winding as an example. A core is built up of thin iron rings, electrically separated from each other by means of such material as paper; this is done to prevent heating due to currents which, if it were composed of a solid mass, would circulate through the length. By means of a non-magnetic spider frame, this core is secured to the rotating shaft. On it are wound the insulated conductors, in the form of a closed spiral, the external part of every turn of which cuts the magnetic circuit twice in a revolution, the impulses of each turn being added. The ends of each section of the spiral are connected to a pair of commutator bars, on which the brushes rest, and by which communication with the external circuit is established.

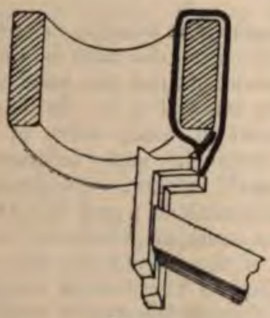

FIG 4.

The commutator is built of bars of copper insulated from each other, and the brushes are set to bear on diametrically opposite sides; each bar in turn is brought into action twice in a revolution, and conveys the current alternately in a positive and then in a negative direction, as it passes under the brushes.

The direction of the current in the conductors is shown on Fig. 5 by means of arrows, and the commutator bars, which for sake of clearness are reduced in number, are shown with their connections, the sections being defined by the portions contained between contiguous bars. It will be seen that the currents in each half converge at the brushes, and as each section belongs first to the right and then to the left, two impulses are given to it in each complete revolution. As the armature revolves, the sections now belonging to the side marked south pass to the side marked north, and below in the reverse order. The lines of force, which cross between the poles and the armature, are cut by the conductors on the right from below, and on the left from above; hence on either side the currents will flow in opposite directions round the spiral, the two streams entering the brush in the same direction.

These currents surrounding the iron core necessarily magnetise it, and the polarity which they impart differs in direction to that of the field magnets. The two sets of lines of force are superimposed, with the result that a fresh distribution of field is produced, Fig. 6, and the line dividing the core into two halves, across the diameter at which the lines of force enter from one side and emerge from the other, which is called the neutral line, is now oblique to the plane of symmetry. Changes in the strength of the current cause the position of the neutral line to change. The brushes, to work without sparking, have to be set a little in advance of it, and when its position changes the brushes have to follow suit. This occasions the chief need for attention in working the machine, as there is always excessive wear of the commutator when the brushes are improperly set, and an accurate comprehension of what takes place is of material assistance in the management. In Fig. 5 the section shown is just on the boundary between the lines of force entering the core on one side and emerging on the other, where the field is nil, so that comparatively little difference of pressure exists between contiguous bars, and the section has just been closed on itself by the two commutator bars being bridged by the brush. Up to this point the section has been carrying the same amount of current as all the other sections on the same side which are in series with it, but now being momentarily short-circuited, the strength and direction of current will depend on the field through which it is passing. To prevent sparking, the brush has to be set in advance of the neutral line, at the point where the density of the field is just sufficient to stop the current, and raise it in the opposite direction to the same strength as that flowing in the coils on the side to which it is just passing. Now, in virtue of the property of self-induction possessed by an electric current, which is greatly augmented by the presence of iron in the core, and which is analogous to the inertia of a ponderable body,

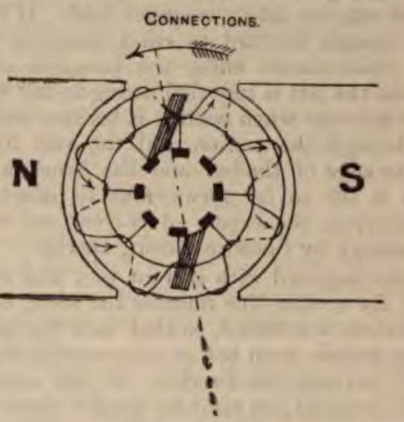

FIG. 5.

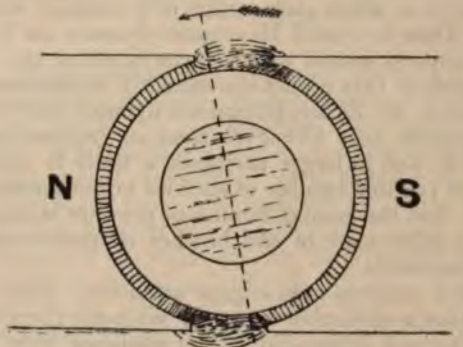

FIG. 6.

the current contains a small store of energy, and this has to be given up before the current can be stopped, and in raising it again in the opposite direction, energy is absorbed, both in consequence of the self-induction and the resistance of the section. The amount involved varies as the square of the current strength, therefore, with heavy load, a stronger reversing field is required It, however, unfortunately happens that the obliquity of the field due to the armature reaction increases with current in a direction which leaves the brush in a weaker field, whereas a stronger one is wanted, hence, when load is added, it is always necessary to advance the brushes in the direction of rotation into a stronger field. If they are not placed far enough forward to effect complete reversal by the time commutation ends, the progress of the main current from the left is impeded owing to self-induction, so that at the moment when contact is broken part only finds its way through the section, and the rest forms an arc between the edge of the bar and the brush, and again, if the brush is set so far forward as to effect more than complete reversal, the excess of current set up can only spend its energy by likewise causing sparks.

In a motor supplied with current in a like direction, the position of the neutral line remains the same, but the direction of rotation is reversed, so that now the action of the field on the section, even before commutation commences, is tending to reverse the direction of the current. The sequence of assisted and retarded motion remains the same as in the generator, and the brush has still to be set on the same side of the neutral point, the lead, as the displacement of the brush is technically called, now becoming negative, and will have to be increased with load in the direction opposed to the rotation.

No machine has hitherto been constructed with an absolutely fixed position for non-sparking point, but to a great extent it is under control by proper shaping of the pole-pieces and by increasing the strength of the field, when as fewer turns of the conductor on the armature are required to produce the pressure, the obliquity of field and self-induction are reduced. The energy of the spark can also be diminished by multiplying the number of sections; in small machines this can be pushed to the point at which the commutator bars become so thin that a brush of proper thickness to collect the current without heating would bridge more than two bars at a time, and in large machines to the point at which each section only contains one convolution. Thus in a small Manchester dynamo for 100 volts and 24 amperes wound with 480 convolutions, the number of commutator bars cannot conveniently be increased above 40, whilst in an Edison-Hopkinson dynamo for 105 volts, 1,100 amperes, only 43 convolutions are required to obtain the E.M.F., and in larger machines a limit is reached at which the possible number of sections in the commutator is so small, that the great difference of pressure between them makes an adjustment of the brushes to prevent sparking almost impossible.

The field magnets next engage attention. They may be made either with double or single magnetic circuit, as the Manchester and Edison-Hopkinson machines, Figs. 7 and 8. The single circuit is the most simple, and will best serve for illustration. The best results are obtained with wrought iron, because, as may be seen from Fig. 2, more intense magnetisation can be obtained with less expenditure of force. This, however, chiefly resolves itself into a question of cost and expediency. In some machines cast iron is exclusively used, and in some, as the Manchester, there is a composite circuit. In the Edison-Hopkinson only the softest annealed wrought iron is used throughout.

The lines of force in passing from pole to pole choose the path of least resistance, only those penetrating the armature core being effective. Owing to the small distance between the core and the polar surfaces the major portion pursue this course, but inevitably some, emanating chiefly from the outside of the pole-pieces, pass external to the armature and are wasted, and if other masses of iron, such as the bed-plate, are in too close proximity, an undue number may be lost, and even in the best designs the amount is from 20 to 25 per cent.

The larger the section of the armature core in proportion to that of the magnet the less strongly it will be magnetised; it attracts more lines and reduces the waste, but the increased quantity of iron enclosed by the armature conductors tends to increase the obliquity of the field, so that less current in proportion can be carried, and it is therefore desirable to take a mean value; this, when only wrought iron is used, is arrived at when the permeability of the armature core is only slightly greater than that of the magnets.

It is undesirable, on the score of economy, to saturate the iron by magnetising it beyond the point at which the permeability begins to fall away rapidly. On the other hand, if the induction is too low, any irregularity in load or speed is liable to produce magnified fluctuations in the pressure.

It is important that the bored faces of the pole-pieces should embrace the greater part of the circumference of the armature, otherwise the area of the air space across which the lines of force have to pass, being restricted, a greater magnetising force is required, and there would be more waste field. In very large machines, however, restriction becomes a necessity; for without it the balance between the current-turns on the armature and the magnets could not be maintained.

It will often be found that in machines with a weak field the tendency to sparking is corrected by increasing the interval between the polar tips, this being necessary to ensure proper gradation of field for reversal, but the lead is then considerable. In the Manchester dynamo, in which the field is powerful and the air space small, the reduction in the gap between the tips to 5deg. or even less decreases both speed and lead. In this case there can be little doubt that the leading convolutions of the section under commutation enter the field on one side of the neutral line before the rear one emerges from the field on the other side, and so reversal is expedited, and the lead varies less with different loads.

The number of current-turns required to give the same magnetisation to iron is proportional to its length, no greater length of magnet limb should therefore be used than is consistent with a sufficiently shallow winding to allow the heat to escape. The proportions of Edison's 60-light dynamo, as brought over to this country nearly 10 years ago, was referred to, and the reduction in length of the field magnets made by Dr. J. Hopkinson, whereby, still using nearly the same weight of copper, he was able to produce a field of so much greater strength that it permitted of a fresh arrangement of the armature conductors, and the machine gave double the output.

Two different methods of winding magnets are employed. For series-wound machines the main on its way to the external circuit is carried round the magnet limbs, using a thick wire with few turns, Fig. 7. In shunt winding, Fig. 8, a separate circuit of many turns of fine wire proceeding directly from the main terminals is employed, carrying only a small current. Compound winding is a combination of both methods; each has its special applications, but in all the same magnetisation is produced, provided the product of the current into the number of turns is constant. Owing to the loss of energy which takes place in sending a current through a conductor against its opposing resistance heat is always generated, and the dimensions of the wire have to be proportioned accordingly. In series winding the length is determined by the number of current-turns required, and the section by the strength of current. In shunt winding there is for every machine a proper diameter of wire proportional to the linear dimensions and to the E.M.F. which gives the right number of current-turns, but the length is arbitrary. If it be doubled, the resistance is doubled, and the current, therefore, halved, but the total current-turns remain nearly the same. In practice the length is therefore determined solely by considerations of economy. With the longer wire there is less loss of energy, and, therefore, less heating, but increase beyond a certain length is prohibited by the expense. For small machines, where the radiating and conducting surfaces are proportionately large, and the depth of winding small, the heat can readily escape, and 2,500 yards to 3,000 yards for every 100 volts at the terminals is sufficient. In large machines, especially when high efficiency is aimed at, double this length is sometimes used.

Of the total pressure generated, part is absorbed in overcoming the resistance of the armature and the magnet winding, the rest being available at the terminals for use in the external circuit. With increased load more energy is required to drive the increased current round the armature, and at the same time the reaction on the magnets is increased, those coils included between the brush and the line dividing the armature symmetrically between the poles, act in direct opposition to the magnet coils, tending to weaken the field, whilst the remainder tend to twist it. And the greater the twist the greater the lead, so that unless the magnetising force or the speed is increased, the presure at the terminals must fall as load increases. In the shunt machine this occurs in threefold manner, as the reduction of pressure at the terminals, consequent on the armature loss and the lead, results in less current being driven round the magnets. The effect in the series machine is different, the pressure being augmented, because the magnets being excited by the main current increase in strength as it rises.

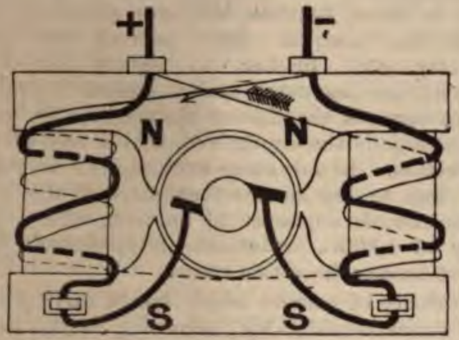

FIG. 7.

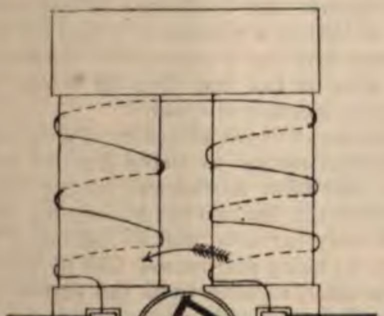
In Fig. 9 the results for constant speed are plotted. The volts in the shunt machine fall, whilst those in the series rise as the current rises, by employing compound winding the mean of the two effects is obtained, and the volts can be kept practically constant over a wide range, without change of speed. By proper proportioning, the pressure can be made to rise slightly with increased load, and the fall in speed of the engine, which to greater or less degree occurs wherever mechanical governors are employed, can be compensated for, and even the varying loss of pressure with different loads in a long main conductor is under control. It is not, however, possible to compensate exactly in such cases as lighting circuits, where some lamps are close to the dynamo and some far away.



In machines in which the convolutions on the armature are excessive, it is necessary that the series winding bear a large proportion to the shunt, in order to compensate for the loss of pressure due to high resistance and the obliquity of the field, but where the magnets are relatively powerful the correction is small. For example, in a Manchester dynamo for 100 volts and 320 amperes, the series coils at full load contribute 45 per cent. of the whole magnetising current, whereas in the Edison-Hopkinson for the same output it is only 20 per cent., from which it follows that in the latter the lead is less variable.

In the series dynamo, up to the point at which the magnets become saturated, the current and pressure grow together, beyond this, supposing the speed to remain constant, the waste field and the loss due to armature resistance are both increased by the greater current, so that at the terminals the E.M.F. will begin to fall away again.

The chief uses of the series machine are for motors, or for high tension for arc lights, worked in series. As a motor, where it has to be started and stopped with the load on, the resistance of the magnet coils added to that of the armature moderates the flow of current when switched on. There will, however, be great changes of speed with variable load, unless a regulating resistance is applied. For the propulsion of locomotives the series-wound motor possesses the advantage of exerting a very powerful torque at slow speeds, as the back E.M.F. generated is then small, which not only adds to the force of the armature but also strengthens the magnets. For arc lights the magnets should be well saturated, otherwise fluctuation in pressure and current occur with every variation in the resistance caused by the distances between the carbon points changing; when these close there is a rush of current which with non-saturated magnets would be still further augmented by increase of pressure, due to the consequent increased excitation, and this acting on the mechanism of the lamps would unduly separate the carbons, causing in turn an excessive fall of current.

In the shunt dynamo variation in load, as already explained, causes considerable variation in pressure in the inverse sense. Where constant pressure is required as in supplying incandescent lamps, compound machines are therefore generally employed, but where intended to run in parallel, and where changes of load are small or the engine governor is not sensitive, shunt machines answer as well. For charging accumulators they are necessary, as if by slipping of the belt, or other cause, the pressure falls below that of the opposing E.M.F. of the cells, the current runs back into the dynamo, making it run as a motor. This, however, in the shunt machine tends to increase the speed, and checks excessive discharge, but if it were series wound the polarity would be reversed, and it would generate current in the same direction as that flowing from the cells, causing a violent discharge to the detriment of both. A shunt-wound motor can be run at approximately constant speed with either full load or no load, but care must be taken to avoid such overloading as would bring it to a stand, when by all back E.M.F. being done away with excess of current would injure the armature.

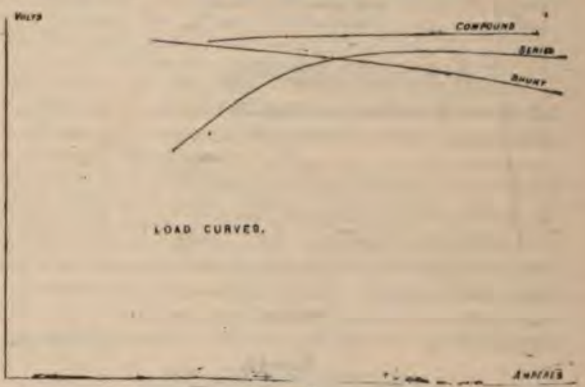


FIG. 9.

In a dynamo at rest there will be little, if any, magnetism. After starting, excitation depends on an infinitesimal current from the armature reinforcing the field, whereby a further increment of pressure is established, and the mutual reaction soon raises the strength to the full limit. The time required depends on the residual magnetism and on the proportion of iron to copper, and may vary from a few seconds to many minutes, being greatest in a new machine. For every speed there is a point at which the product of the current into the resistance creates an opposing force equal to the pressure generated by the armature, and no further rise of pressure can take place without increase of speed. In a series machine, as excitation is effected by the main current, the circuit must of necessity be closed, but in the shunt machine, if the main circuit be closed at starting there will often be a difficulty in exciting, unless the speed is temporarily raised above the normal, for owing to the path of low resistance offered by the main circuit, the pressure at the terminals is pulled down, and less current flows round the magnet circuit. In the compound machine, as both sources of excitation are employed, it is generally best to keep both circuits closed.

When it is desired to change the direction of rotation, the lead of the brushes has to be changed to the opposite side of the neutral line, and their inclination reversed, so as to prevent them tripping against the commutator. It is also necessary to change over the connections of the magnet coils (which is most conveniently done by crossing the leads from the brushes), for as the armature conductors now cut the lines of force in the reverse direction, the positive and negative sign at the brushes is changed, and if the connections were unaltered the reversal in the armature would change the polarity of the magnets, which would again reverse the flow in the armature, and so on *ad infinitum*. It follows, that while it is immaterial which pole be north and which be south, there is only one way of connecting up for each direction of rotation with which the machine will work.

When working with the same induction, the proportion of copper to iron in various sizes of machines will remain approximately the same, and with the same peripheral velocity the outputs will be nearly as the weights. Fig. 10 shows the general form of the curve for various sizes of Edison-Hopkinson machines, for from 12 to 150 e.h.p. It should, however, be noted that in the case of the larger machines, the curve of actual velocities is drawn to suit direct drive off the shaft of such engines as those of Messrs. Willans and Robinson, otherwise velocities 25 per cent. greater would be admissible. It is not desirable to stint the copper, but it should be so disposed that the energy lost is a minimum; for this purpose, on the armature there should be a few turns of large section, and on the magnets greater length or section, according as they are shunt or series wound. These conditions can, however, only be fulfilled when the iron is also plentiful. If it were not the same quantity of copper might still be employed, but with diminished efficiency, and it can only be in special cases, where light weight is of greater importance than either efficiency, durability, or cheapness, that little iron can be tolerated.

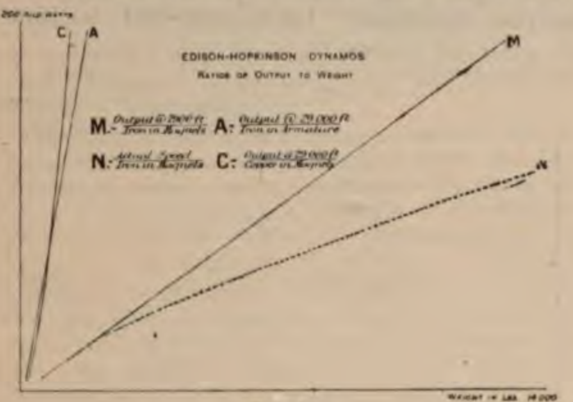

FIG. 10.

The load which a dynamo will carry is limited either by such strength of current being attained that any increase would cause a rise of temperature injurious to the insulation of the conductors, or else by the obliquity of the field and self-induction becoming so great as to prevent proper reversal in the sections under commutation. The load is therefore greatly dependent on the relative section of the magnets and armature and current-turns on each, the number of the latter being affected by the resistance of the air space.

In the drum armature the self-induction is least, whilst in the ring the ventilation is generally better, the result being that for small machines, electrically, there is little to choose between them, though for these and for high-tension machines there are points in the construction of the ring which have special advantages.

In the drum, as the coils overlap at the ends, if the insulation of a section fail it is generally necessary to rewind the whole; and also owing to the overlapping there may be great difference of pressure existing between contiguous wires, tending to produce short circuits. In the ring armature each section is separate, so that short circuits are less easily produced, and repairs more easily effected. For large sizes, however, induction troubles are greater, and as large drum armatures can be wound with a different arrangement of end connections and in a more symmetrical form, by using spiral strips, they are to be preferred. The round conductors are replaced by bars which allow of a larger section of copper, as the insulation takes up less room. It is necessary to make the bars thin on the face in order to prevent undue heating, caused by local currents started in them, between opposite sides as they pass through the unequal field between the polar tips. Frequently, still further to reduce loss from this cause, they are laminated, and a gradual widening of the air space towards the tips of the magnets, by preventing abrupt change in the strength of field is also efficacious in this direction. In a dynamo working with an induction of 12,000 lines to the square centimetre, if the width of a solid bar exceeds a quarter of an inch, with a peripheral velocity of 1,800ft. per minute, it is difficult to prevent excessive heating from this cause.

The density of current which can be carried by a conductor varies considerably, according to the intensity of these eddy currents, the conditions of temperature under which the machine is working, length of runs, depth of winding and section and means for ventilation. No general rule can therefore be given, as it may vary from 1 to 2·4 amperes per square millimetre in the magnets, and 2·5 to 6 in the armature, but it is not difficult, from experience in a few cases, to determine the proper size for any particular winding.

In selecting a machine it is always desirable to ascertain what is the rise of temperature to be expected after working. It used not to be uncommon to find machines with armatures which heated to nearly boiling point of water, and though many have lasted for years, there is always a gradual decay of the insulation going on, which, together with expansions and contractions of the metal and working strains, finally loosen the conductors in their places. The tendency has been constantly to reduce the temperature, and the Admiralty specification, which is intended to cover the most trying conditions, limits the rise to 40deg. F. Such a low figure, however, entails a very expensive machine, and for general purposes fully double this rise may be permitted without any risk whatever. Rise of temperature in the armature also has the effect of reducing the pressure, because the coefficient of resistance of copper increases, so that in a machine in which the current density is high there may be a perceptible difference in the performance after it has had time to warm up, which will necessitate an increase of speed.

The commercial or net efficiency of a dynamo is the ratio of the electrical energy, available for use in the external circuit, to the total mechanical energy absorbed. The difference between the two being made up of losses due to friction, to eddy currents, and to heating of the armature core due to its being magnetised first in one direction and then in the other, together with the further losses due to armature and magnet coil resistances.

The electrical or gross efficiency is the ratio of the power available in the external circuit to that part of the energy transmitted by the belt which is converted into electrical energy—that is, to the electrical energy in the external circuit plus whatever is lost in overcoming the magnet and armature resistances. In the earlier machines the losses from all these sources, especially from armature resistance, were so high as often to reduce the net efficiency to below 60 per cent. In recent machines it is rare to obtain a return of less than 80 per cent., and in the best machines it amounts to over 90 per cent., sometimes reaching 95 per cent., but small machines, or those run at very slow speeds, cannot be expected to give so high a return, as the resistance of the armature conductors will be high. For this reason it is only for the sake of coupling direct to the engine shaft, thereby gaining in compactness and absence of belting, that very slow speeds are much employed. Very high speed, again, possesses the same disadvantages common to its use with other classes of machinery, and a velocity of from 1,800ft. to 3,000ft. per minute at the periphery of the armature is now commonly adopted.

The mechanical strains which are likely to be injurious are confined to the armature. The chief one is the stress on the conductors, tending to make them slide on the surface of the core. In small machines bands of brass wire wound closely round the circumference produce sufficient adhesion to keep them in place, but in large machines it is desirable to provide a positive means of driving, for which purpose radial metal pegs can be let into the core. A considerable factor of safety is required in all parts of the armature, because accidental short circuits in the external circuit are liable to cause sudden rushes of current, producing enormous transient strains, which may cause the conductors to be displaced, and may permanently strain the shaft. The latter effect is specially liable to occur in machines in which, owing to the shape of the pole-pieces, the magnetic attraction of the core is not equally balanced. This is a defect sometimes found with single-circuit dynamos in which the section at the extremity of the poles is much reduced by being tapered off. The armature may then be attracted towards the magnets with a pull amounting to many times its own weight, and even under normal conditions of working, this is liable to make the bearings heat. It can, however, be remedied by placing the armature eccentrically in the fields, so that on the side where the pull would be greatest the air space is increased. There may also be end-pull if the core projects unequally beyond the bore of the magnets.

The materials at our disposal for insulating purposes are divisible into those which are rigid or flexible, combustible or incombustible, damp or oil proof, or the reverse. All the most useful qualities cannot be combined in one material. For the insulation of the commutator it is difficult to imagine anything more suitable than mica; its price is, however, too high, and it is not sufficiently flexible to be applicable for all purposes. Fibrous materials, treated with varnish or indiarubber, are almost compulsory for the insulation of the conductors. These will withstand as high a temperature as, on other grounds, it is at all desirable to permit, and with care and cleanliness may last for years. There is, however, no denying that, owing to their yielding and absorbent nature, they form the weakest link in the structure, and any small leakage set up is rapidly extended, owing to the charring of the material. Possibly in the future the skill now so abundantly brought to bear on the production of artificial substances will place fresh materials at our disposal. In general design the dynamo has arrived at a stage at which little radical change can be expected. The efficiency is already so high that increase is scarcely possible, and, as far as consideration of cost of power is concerned, a difference of 5 per cent. one way or the other is rarely of much importance, but seeing that a high efficiency is accompanied by a reduction in heating, in sparking, and undue strains generally, it betokens a thoroughly sound and reliable machine, requiring the minimum of attention, and, therefore, to the purchaser carries with it a warranty of satisfactory performance.

Future improvements will probably chiefly consist in details of construction, labour saving in production, and perhaps new and less perishable materials for insulation. Abolition of the variable sparking point is the most important problem which remains to be solved. In working, the dynamo will not stand neglect or unskilful handling, and amply repays a moderate amount of care bestowed on it.

I have to express my thanks to Messrs. Mather and Platt for the facilities which they have afforded me at their works for the preparation of this paper.

GARRETT'S MAGNETO BELL.

Magneto-electric bells have certain well-known advantages over ordinary electric bells, but of these perhaps the most eminent two are that they are practically everlasting, and that they do not develop faults in the line to which they are connected, since the E.M.F. is only applied to the line when they are in actual use.

We herewith illustrate a new magneto-electric bell, patented by Mr. T. A. Garrett, constructed by Mr. James Pitkin, of 56, Red Lion-street, Clerkenwell, E.C., which probably will come into extensive use, having many qualities to recommend it. It is of strong construction and well adapted to stand the somewhat rough usage which such bells inevitably meet with when placed in the hands of the public. From the simplicity of its construction we imagine it will be manufactured more cheaply than any other magneto bell we have seen. This simplicity has not been obtained by the sacrifice of loud ringing; in fact, it seems to us to be louder than other magneto bells. We understand that a very great number of experiments have been done in making this bell simple and loud.

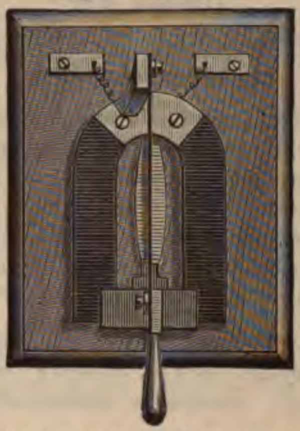

Fig. 1.—Garrett's Transmitter.

The transmitter consists of a single horseshoe permanent magnet, between the limbs of which there is a soft-iron core wound with wire, and a spring carrying at its free end a soft-iron armature, which can vibrate over the poles of the magnet and the end of the iron core. When the armature is pulled aside and let go it vibrates to and fro, and in so doing acts on the magnetic field so that an alternating current is generated in the wire round the iron core.

The transmitter and receiver are very similar in construction, the chief difference being that in the receiver the armature consists of two pieces of soft iron which are both attached to the spring, but one of these is magnetised only by the north pole of the permanent magnet, while the other is magnetised only by the south pole, and the ends of these pieces of iron are so bent that they are near to the end of the soft iron core but on opposite sides of it. When a slowly-alternating current is passed through the wire surrounding the iron core each of the pieces of iron forming the armature is alternately attracted and repelled by the end of the core, and since one is being attracted while the other is being repelled the armature moves as a whole from side to side, and carries with it a hammer which hits a bell. Since the cores in both the instruments are stationary, there is no necessity to have flexible connections, and consequently there are no loose wires which are liable to be broken.

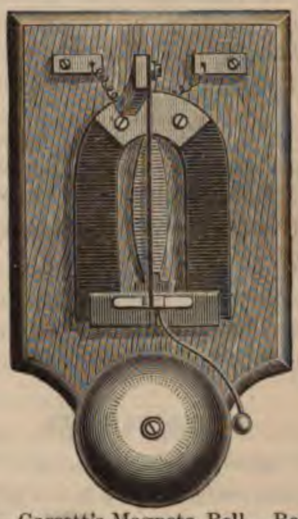

Fig. 2.—Garrett's Magneto Bell.—Receiver.

The circuit is always complete, therefore if this bell is used in a mine there will be no danger that a spark may cause an explosion. But probably the most extensive field for it will be in connection with telephones, and its arrival at the present time is most opportune, owing to the expiration of the telephone patents, and it should prove admirably adapted for ordinary house work.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence ; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices :

139-140, SALISBURY COURT, FLEET STREET,
LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months		6 months		12 months.
United Kingdom............	3s. 3d.	...	6s. 6d.	...	13s. 0d.
Within the Postal Union	4s. 4d.	...	8s. 8d	...	17s. 4d.
Other Places..................	4s. 10d.	...	9s. 8d.	..	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VI. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

We may occasionally follow the lead of our American Contemporaries, especially when they point out a serviceable way. They are not backward in asking their friends to do all they can for the welfare of the paper. We ask our friends to remember us. No Paper that we know ever refuses Subscribers or Advertisers. Nor do we; in fact, we invite them, believing that they will get full value for their money.

Specimen copies of the paper will be sent on request.

THE POSTAL TELEGRAPH DEPARTMENT.

The work of this department being under Government control, cannot be subjected to the close observation that is given by competitors to ordinary manufacturing processes. The general public base their opinion as to the efficiency of the department upon the manner in which they are individually served. A few people are able to compare our telegraph system with those in vogue in America and on the Continent. Those who can make such comparisons are almost unanimous in favour of our own department. The service is admitted to be about the best in the world. A little examination into what such a statement means will show that to obtain this position not only must the *personnel* of the department be good, but the instruments and apparatus used must be the best of their kind. The progress in modifying instruments and in perfecting the organisation is unseen to the outsider. Now and again a report in a Blue-book tells of this progress, but usually the Blue-book is put into the hands of the public at a time when its contents to the workers in the department savour of ancient history. We have been able to glean a fair history of the more recent work in the department, some of which may be referred to without interfering with red-tape regulations. We have already referred to the experimental telephone line in progress between London and Paris, but it may be news to some of our readers that the electrical branch of the department has devised a new telephone said to be equal to the Gower-Bell instrument. A number of minor improvements, each of which, of course, tends to make telephonic apparatus more perfect, have been introduced. Thus, seamless flexible tubing is used for the hearing tubes in the Gower-Bell instruments, a non-polarised relay has been devised and introduced at Newcastle, as has a new handle switch and an adjustable elbow rest, also non-polarised indicator relays, switchboard telephone tablets, etc. Improvements have been made in the details of the Newcastle multiple switch. Experiments have been made with a new form of induction coil; and a variety of apparatus has been subjected to careful trial, though in the majority of instances it is found that such apparatus is no better than what the department has in use. Thus it will be seen the official world has been kept thoroughly conversant with the possibilities of telephony. Direct communication has been held between London and Glasgow over the new 200lb. copper wires.

There is no doubt about the progress of the Telegraph Department. Year by year greater demands are made upon their circuits. These demands have to be met, sometimes by arranging new circuits, sometimes by introducing new apparatus, sometimes by modifying the old apparatus. Thus, by modifying the apparatus the speed of working the Irish cables has been increased from 25 to 30 per cent.—in other words, while 200 or 230 words used to be sent, 250 or 300 are now sent. Elsewhere, we reprint from the *Times* a full account of the changes in communication with Germany introduced by the department since the work came into its hands. Improvements, simple in themselves, are being constantly introduced; thus a long series of experiments has resulted in the design of a satisfactory arrangement for use at repeater offices, by means of which the sounders are normally silent. The value of this will be better understood by the initiated than by the outsider. Formerly the sounder was not usually silent, and the call was not always effective at once. From silence to sound should arrest attention immediately. Improvements have been introduced with all kinds of working—simplex, duplex, quadruplex, and multiplex—so that the speed of signalling is gradually increasing all round. It will be seen from these brief remarks that the officials are constantly alive to the necessities of the age, and no effort is spared to keep the telegraphic system in the highest state of efficiency. It must be remembered also that economy has to be considered as well as efficiency, and in the attempt to find some substitute for platinum many experiments have been made with various metals and alloys, as have experiments upon the quality of steel used for magnets, the latter of which led to the conclusion that the steel from French makers was better for this purpose than the steel from English makers. Altogether the officers of the department are to be congratulated upon their energy, activity, and, from the public point of view, their success.

A NEW PERIL.

Such is the title of an article in the *Speaker* of January 24, following the lead of *Nature*, and some of our technical contemporaries. The boom may be termed the Kensingtonian condemnation of electric and other railways that may or may not interfere with their very delicate instruments and investigations. No doubt it is a bother to be troubled with these necessary works of modern civilisation, but they are works we cannot very well do without; while the professors can at any rate move elsewhere, or, if they remain, take a few precautions over and above what they take now. It seems to have become an unpleasant and an unwelcome duty for us to point out little lapses of Kensington. If not, why was the *Speaker* brought to us, marked, and with a request to notice? We are compelled to say that of all the statements made with regard to the damage to physical laboratory work, there is but a grain of truth in any of them. We would undertake to erect a laboratory in, or over, or under Paddington Station, and let the whole Great Western traffic be run electrically without troubling one iota, or measurements being affected in the slightest. We have been told of the troubles arising from vibrations caused by walking. Is there a single man of scientific repute that does not know the cure? If not, let him sleep in a hammock and consider. Exterior "magnetic tornadoes," as the *Speaker* calls them, are to be rendered as harmless as the autumn winds of Vallombrosa to the towers and turrets of the Spanish castles. The *Speaker* goes on to say: "Nothing but an overwhelming public necessity should be allowed to interfere with these institutions on which private funds have been lavishly spent for the public good. If their claims are ignored, the possibility of offering a good scientific education to the sons of middle-class and working men is endangered."

This is sheer unmitigated nonsense, and if such statements are made authoritatively by the South Kensington or any other interested people they are stating what is absolutely untrue, and they know it. The world of business is not going to stand still because certain delicate electrical measurements are to be taken. In the first place, few, if any, such measurements are required in "the teaching of the sons of middle-class and working men." They are, perhaps, required in the experimental work of the professors, but money is not subscribed to allow a few enthusiasts to investigate into any and every direction their fancy leads them—the money is subscribed for the teaching of the "sons of middle-class and working men."

Again, the *Speaker* says: "A proposal has been made to run a subway between South Kensington and Praed-street, and powers to propel the trains by electricity are asked for. The course marked out for the line runs under one of the physical laboratories of the Royal College of Science, and is separated by the breadth of the road only from the others. It is also to pass within a few yards of the City and Guilds Central Institute for Technical Education. That the line might be in some respects convenient is quite possible; that if the powers to employ electricity are granted and used as at Stockwell, existing physical laboratories will be rendered useless, is certain. The South London line is surrounded by an iron tube which acts as a 'magnetic screen' and serves to diminish its magnetic effects on external objects. No such precaution is, as far as we are aware, to be adopted at Kensington, and in this respect, at all events, the proposed line is likely to be the more injurious of the two. To the laboratories of the Royal College of Science teachers are brought by Government funds from all parts of the country. Every summer 200 come from far and near to hear lectures and to go through a course of laboratory work."

We should like to point out that the majority of these 200 science teachers brought up from the country to be taught, probably have nothing at all to do with delicate electrical apparatus. Some are chemists, some are mechanics, some are mathematicians; some are students in one subject, some in another, and only one small portion are "electrical." Suppose the railway company, for the sake of these few, puts up a "magnetic screen," no doubt all the experiments required by the "science teachers" could be performed.

After saying this much, we will admit that if the opposition to the electric railroad had contented itself with statements of fact and truth, their case would have been stronger, but no such attempt has been made. What has been done has been an attempt to lead the public to conclusions by means of statements that are untrue. A considerable expense might be incurred in making the laboratories fit for delicate experiments if the railway is proceeded with, and that expense should be borne by the railway if its promoters did not alter their plans, but to say that such a railway would practically neutralise the value of South Kensington as an educational establishment is absurd. The majority of students there have nothing to do with delicate measurements—they have nothing to do with electrical measurements at all; and the "sons of middle-class and working men," even if they are students of electrical subjects, do not require measurements of the amazing delicacy suggested by the *Speaker*.

OVERHEAD WIRES AGAIN.

The recent snowstorm in America has once again demonstrated the difficulties that must arise from the continued use of overhead wiring systems in large towns. The *Times* telegram of Monday, from New York, said: "All the electric light and telephone wires are down, and last night not an electric light dependent upon supply companies was burning in the city." It is hard to credit such a sweeping statement, as we all know that while overhead wires are common, a good deal of underground work has been carried out. But if the damage to electric light wires is bad, that to telegraph and telephone wires is worse. Practically, telegraphy and telephony in the district swept by the storm is at a standstill, and the cost of renewal will be enormous. The intermingling of electric light, telegraph, and telephone wires caused phenomena described as "balls of fire ran along the streets following the broken wires." It may be a source of gratification that nothing worse than arcs in the streets were observed, when many fires might have been caused and lives lost. So far as human knowledge goes, there is no country or district upon the face of this world but is at times subjected to storms sufficiently strong to cause great damage to overhead wires. Especially is this danger to be considered when we know that such wires are run for purely economic reasons. The initial cost is far less than the cost of underground work, but a few more such disasters as befell the telephone wires in London a few years ago, and now have to be deplored in New York, will go far to prove that in the long run it is cheaper and better to adopt an underground scheme from the first. Where initial cost rules the question, overhead wires are certain, and it is as certain also that those overhead wires will be put up as cheaply as possible. Promoters and managers are too prone to consider the present, and to trust to luck for the future, than to expend a larger amount to attempt to ensure future safety. We have never been convinced but that investors would agree to provide the extra capital if the matter was properly put to them. With one or two possible exceptions investors are tempted to invest by means of promises, promises that can only be fulfilled under most exceptional circumstances. The annual cost of maintenance of these overhead systems is, we believe, considerably in excess of what would have to be similarly paid for underground work, and the annual outlay thus saved would go a long way to pay the dividends on the extra capital initially required. All these things have to be considered from the £ s. d. point of view. Pure science may say this, or may say that, but those who run companies care only for the statements of science so far as they will gull the investing public. The sole question, then, is, will the annual savings in maintenance, and the periodic savings because of general breakdowns, suffice to pay dividends on the extra capital required to prevent this increased cost of maintenance and these breakdowns? We contend that in all thickly-populated centres the extra outlay is warranted.

MEASURING MAGNETIC RESISTANCE.

We have taken up a position stated in several articles lately written differing considerably from the present conception upon the theories, more particularly as affecting practice, of magnetic action in iron. We have preferred to consider the whole effects in a magnetised body of iron as a magnetic circuit, with functions and simple laws comparable to those of a conductive circuit and Ohm's law. We have further suggested the preparation of a set of standard magnetic resistances, similar to those now standardised in the ohm, etc., so that manufacturers can prepare their manufactures to specification as copper is now prepared, and could guarantee their iron as of so much per cent. magnetic conductivity for a certain standard, shape, and section. We are pleased to learn that a large manufacturing firm in the North have commissioned one of our best-known electricians to test and report upon 50 different specimens of iron for dynamo magnets of different composition and processes of manufacture, so as to enable the said firm to undertake orders and guarantee their iron. The whole electrical profession will take a keen interest in such an attempt to deal practically with this most important electrical problem, and the example thus set will no doubt be imitated, and from the results obtained a practical standard may be evolved. We are not aware in the proposed tests whether our suggestion for magnetic conductivity is to be acted upon, or whether, as is most probable at present, the tests will be taken along the lines of ordinary theories. We shall be interested to be informed in what units the measurements are to be made; whether permeability, hysteresis, and the rest are to be separately tested, or whether the magnetic conductivity as a whole is to be taken. We should like to know whether the magnetic conductivity will be taken at limits the section can carry well, and whether the overloaded iron at the point of saturation and increased resistance will be considered from a similar point of view as an overloaded wire at the point of saturation and fusion. Now that the question has actually become one of practical measurement, it would be well for such important points to have definite attention given to them.

IN COURT.

The action Berry *v.* Challis at the Westminster County Court is instructive. Many points would bear commenting upon, but there is one which deserves special attention. The plaintiff claimed that work and materials were of the very best description, and about this there seemed to be some dispute; but failure did take place and was attributed to the dampness of a cellar. He naturally contended that "wet or damp was a deadly enemy to electricity." We have long argued that the probable users of electricity know as much about its performances as the suppliers do of the North Pole—that is, nothing. Suppliers might be supposed to know something of the matter, and ought to advise their clients. In this case it was known, or it should have been known, to the supplier of the apparatus, that dampness in the cellar was one of the troubles he had to provide against, and it ought to have been provided for. The world now must believe there is another "bug" the electricians cannot overcome, in the shape of a damp cellar. This conclusion is, of course, absurd. Wet and damp may be troublesome and cost something to provide against, but to argue that a lamp must go out if the switch is in a damp cellar is to own that electric lighting is impracticable, for we cannot ensure dry cellars or dry anything in this climate. It is a great pity that electrical engineers should make claims and defend their claims on such grounds as these. "Extra work" is a fair excuse for a claim, a "damp cellar" shows lamentable weakness somewhere.

ELMORE'S COPPER DEPOSITING WORKS.

On the invitation of Elmore's Patent Copper Depositing Company, a number of pressmen paid a visit to Leeds on Tuesday to see the Elmore process in operation. The party were conveyed from St. Pancras in Pullman cars attached to the 9 a.m. train, reached Leeds at 1.30, drove to the works, inspected them, and left Leeds again by the 5.30 train, reaching town shortly after 10 p.m., by no means a bad day's work. It is needless to add that the requirements of the inner man were not forgotten on the journey. The programme was carried out from first to last without a hitch, thanks to the organising powers of Messrs. F. L. and Stepney Rawson and Mr. Shurmer, secretary to the company, who accompanied the party throughout.

The depositing works are situated at Haigh Park, Hunslet, a large piece of land about 250 acres in extent, which has, we understand, been acquired by a syndicate whose members are interested in Elmore's Depositing and Elmore's Wire Companies, the latter holding leases of the ground on which their respective works stand. The Midland Railway Company's system adjoins the park, and they have undertaken to build a station on condition that workmen's houses are erected—and there is room for a small town.

At the depositing works the party were met by Mr. Saunders, manager, and the Messrs. Frank and Stanley Elmore, the latter of whom, with the Messrs. Rawson, explained the Elmore process of deposition very fully. On the way to the

MELTING SHED

a heap of rough Chili bars was pointed out, containing about 150 tons of copper. The percentage of pure metal was said to be 97, the impurities present being gold, silver, etc., which are recovered in the tanks. The melting furnace will hold four tons at a charge, but is not at present worked to its full capacity. The copper is drawn off in a molten state into a large ladle fitted on a trolley, which, when full, is run along a short tramway to a shallow well of water. The slag having been poured and raked off the top, the ladle is tipped, and the metal allowed to run very gradually into the water, where it assumes a granulated shape, known as "shot copper." It is afterwards ladled out and stacked for use in the tanks. The slag is said to contain about 12 per cent. of copper, and we understand that when the works are more fully engaged than at present, this slag will be remelted to extract this percentage. It is now allowed to accumulate for future use.

THE BOILER-HOUSE,

which was next visited, contains two double-flued Lancashire boilers by Heaton, 30ft. long by 7ft. 6in. diameter, capable of working up to about 250 h.p. Only one of these is in work at present, and that is not by any means fully loaded. The house is within easy reach of a canal running past the works, so close, indeed, that, as Mr. F. L. Rawson remarked, it will be easy with a jib crane to unload coal from boats straight into the boiler-house. Adjoining this is the

GENERATING-ROOM.

which is light and airy, and contains three Willans and Robinson engines, and three Manchester dynamos by Mather and Platt. Another engine, by Fowler, is being erected, and there is an Elwell-Parker dynamo, which is not now in use. The whole plant, we were told, would, with 240 tanks at work, turn out 25 tons of deposited copper per week. The Manchester dynamos give 750 amperes and 50 volts at 450 revolutions. One of the Willans engines and Manchester machines had been run continuously for seven months without a breakdown. Copper rods, about $1\frac{1}{16}$in. diameter, convey the current from the machines to the tanks, and a switchboard is provided by which the dynamos can be coupled up in parallel or otherwise as required.

THE TANK SHEDS

adjoin the generating-room. We were first shown a new building, which, it is hoped, will be ready for work in a few weeks' time, but which is at present waiting for its tanks. This will be capable of turning out 10 tons of copper tubes per week. The tank shed at present in work is a well-lighted and ventilated building 200ft. by 40ft., and contains 60 tanks, the majority of which were depositing on Tuesday. The current is led into the bottom of the tank, which is packed with shot copper, forming the anode, and out again by wire brushes pressing on the revolving mandrels, which form the cathode—that is, the deposition is upwards. We understand that, as a rule, plates are introduced on either side of the mandrels, and that the function of the shot copper is to reduce the tendency to the formation of sulphate, which after a time practically insulates a portion of the plates and retards the deposition. We saw these plates in the building, but in the majority of the tanks they were absent. The tanks are 12ft. by 20in. by 3ft. 6in.

The feature of the Elmore process is the deposition of the copper on continuously-revolving mandrels, and the burnishing of the metal during the process. The tanks contain mandrels of varying sizes according to the size of the tube to be produced. We will begin with the one we saw first, in which were three mandrels of 4in. diameter. These are cast-iron cylinders, mounted on wooden spindles hydraulically driven in, and having their ends insulated. A continuous line of shafting, ranging the whole length of the tanks, drives the first of these mandrels, the other two being connected by chain gearing with this one. They are so placed in the tank as to be well covered by the solution, and yet not so deep but that their surface can be seen whilst the coating is going on. The burnishers, which are of agate and cover ½in. in width, are given a to-and-fro motion on the mandrels, and we were told that one would take about 20 minutes to get from one end of the tank to the other—that is, a given spot on the mandrel would be

40 minutes before the burnisher returned to it. The Messrs. Elmore stated that this had been found in practice to be a good speed. The largest mandrel is 4ft. diameter by 15ft. 6in. long. The copper tubes deposited on this are used for glycerine making, are ⅝in. thick, and must stand a pressure of 220lb.

The tanks are connected in series, and out of the 60 in the building about 42 or 44 are usually at work at one time. The current employed is 750 amperes, and the drop in voltage averages about ·9 volt; in the 3ft. 6in. tanks it is ·86. Gutters run the whole length of the building, into which the tanks can be drained. As a rule the tank temperature is maintained at about 3deg. above that of the shed, which latter is not allowed to fall below 54deg. Steam heating pipes are provided throughout. The ordinary rate of deposition is ⅛in. per week of 168 hours, and the maximum that has been done is $\frac{5}{16}$in. per week. The density of the solution in the tanks is about 16½deg. Beaumé.

The best week's output was seven tons, and the average is five tons.

Perhaps as interesting a part of the process as any is the operation of removing the tubes from the mandrels, which is carried out in

THE MACHINE SHOP,

which is under the same roof as the depositing-shed. The mandrel is held between three rollers in such a position as to rest on the two bottom ones, while the top exerts a pressure of from 8cwt. to 12cwt. These rollers are moved gradually along the mandrel until the whole of the copper tube deposited on it has been so treated, the effect being to expand the copper sufficiently to allow of the tube being readily drawn off the mandrel. In this shop were specimens of finished tubes from 4in. to 18in. diameter, the latter being intended for papermaking.

In this department the mandrels are fitted with spindles and receive their first film of copper. The latter operation is carried out in a bath, containing an alkaline solution, at a temperature of about 90deg. to 100deg., which reduces the E.M.F. necessary. The machinery in this shop is driven by two Fowler engines, the one working the depositing tank having been running for six months without once requiring to be stopped for repairs. Here, too, is an Elwell-Parker dynamo, which supplies the lighting current for the works.

A building, at present unfinished, adjoining the machine shop, is intended for tanks up to 60ft. long, in which propeller shafts and hydraulic rams can be coppered.

TESTING A TUBE.

We now returned to the office, where it was proposed to carry out a test to show the extreme ductility and tenacity of the Elmore tubes. The test was carried out on a piece cut from a tube that had been supplied to a customer, and labelled 170, SP9. We may here remark that pieces are cut from all the tubes when made, both tube and piece marked, the latter tested, and the results entered in a book, so that a complete record is kept.

Mr. Perry F. Nursey and Mr. Stoker (Easton and Anderson) were deputed to see that the test was fairly carried out. The machine used was one by James Heriot, and had been employed on the Forth Bridge works prior to its purchase by the Elmore Company. Whilst the test was in progress, Mr. Stepney Rawson gave some illustrations of the great ductility and tenacity of Elmore copper from his experience in the French works. The result of the test gave the tensile strain withstood before breaking as 20·9 tons per square inch, and the elongation as 21 per cent. in 10in. It was stated as a basis for comparison that with a drawn tube the figures were about 15 tons and 4 per cent. respectively. Subsequently, attention was called to a case of specimen test pieces which had been subjected to the most rigid proofs of tenacity and ductility.

THE WIRE WORKS

now being erected by the Elmore Wire Company are as yet far from completion, only the walls and the iron pillars for the roof being in position. They are close to the depositing works and occupy an area of nine acres. When finished they will certainly be among the largest of their class—they will, so we are told, be capable of turning out 100 tons of stuff per week. The company will not make the wire themselves, but will cut tubes up spirally into ribbons and sell these to the drawers to draw down to any required diameter. We understood that these spirals have been cut out to a diameter as low as one millimetre.

It will be noticed that we have confined ourselves to a record of what we saw and heard on Tuesday. No figures were supplied which would throw light on what the Elmore process actually costs per pound of copper deposited; and, as a matter of fact, the works have scarcely even now settled down to commercial work. We have preferred, therefore, to refrain from criticising, or from making public the criticisms which were occasionally heard during our visit. We can say, however, that the test mentioned above showed the copper to be of extremely high tenacity, and the fracture exhibited a fibrous condition quite in accord with the claims of Mr. Elmore, though, at the same time, we are bound to say that at present it is impossible to reconcile the estimates given in published reports with the actual cost of the system. The latter seems, according to present knowledge, to greatly exceed the estimates.

We have only to add that Mr. Elmore was unable to be present owing to engagements abroad, and that his sons, Messrs. Stanley and Frank Elmore, are as enthusiastic in regard to the process as their father, have any amount of energy, and no mean capacity of brain. For the rest, to be able to journey to Leeds, spend four or five hours in going over works, and be back in town the same night, seems to us a good illustration of nineteenth century progress.

CORRESPONDENCE.

EXPLANATION WANTED.

To the Editor of the Electrical Engineer.

Sir,—We have for some years been running two dynamos from the same shafting, one giving an E.M.F. of 50 volts, the other 90 volts, and each supplying its own circuit of lamps, all in order, until a few days ago, when, after having the machines cleaned, etc., we found on commencing to run that the 90-volt dynamo would only give a voltage of 50, the same as the smaller machine, engine speed, etc., the same as usual, but when run separately each dynamo gave off the usual E.M.F.

After trying various means to get the right voltage from the larger dynamo without success, an accidental change of position of the brushes on the 50-volt dynamo brought up the voltage of the other, and they ran all right as usual. It is a new feature to me, after nearly 10 years' experience of electric lighting, and I would be glad to know the cause, if any reader will kindly explain.—Yours, etc.,

January 26, 1891. T. R. D.

THE MEYLAN-RECHNIEWSKI ELECTRIC ENERGY METER.*

BY E. MEYLAN.

Everyone engaged in the supply of electric light from central stations knows that these enterprises are seldom very remunerative for the supplier in the present state of things, and this more particularly in the large towns where the conditions of establishment of the system of distribution are very onerous. That this industry may be carried on under the normal economic conditions, the method of supply must be safeguarded by all possible guarantees. The first of these consists in guarding against the squandering of the current in the customers' houses; therefore, contracts at fixed amounts per annum should be reserved for public lighting, where the control is easy. If, as we have seen in several cases, the companies return to this system after having tried electric meters, it must be because these meters do not yet give sufficient security.

A meter may fail in two ways: inaccuracy of indication, and insecurity of working. Under the latter heading are placed stoppages, and miss fires in starting—that is, the case in which the meter does not begin to work at the moment of connection to the circuit, or when the current is turned on to the circuit.

---

* Translated from *L'Electricien*.

Generally, it is the first point to which most attention is paid; inventors always insist upon the marvellous exactitude of their apparatus, and when a professor or the officials of a laboratory test a meter it is equally upon this point that their attention is naturally directed.

From the point of view of the chief engineer of a central station the case is entirely different; it is of small importance whether the meters register to within 5 per cent., if out of every 10 meters there is one which from time to time does not start, or which stops entirely. It is needless to insist more strongly upon this point, all practical men will acknowledge it at once.

It is from the standpoint of this thoroughly-appreciated idea—namely, that beyond all else it is necessary to obtain security in working—that we have, in conjunction with our collaborator M. Rechniewski, constructed the meter of which we now intend to give some description.

As is known to all interested in the subject, electric meters may be divided into two great classes, the continuous integrators and the discontinuous integrators, or the automatic reading instruments.

The first are represented at present by the chemical meters, and by what are sometimes termed motor-meters; they are characterised by the fact that the instrument gives at each instant the quantity sought, that is, $\int I\,d\,t$, or $\int E\,I\,d\,t$, according to the case, and this either by the accumulation of a metallic deposit, or by the fact that the speed of a movable part is at each instant proportional to the electric energy or to the current. The meters of the second class play the part of an operator, taking off at certain equal intervals the figures of the electric energy or the output, the instrument automatically carrying out the summing up of these variable quantities.

The meter constructed by us is of this latter class.

Let us consider the various organs which enter into the composition of a discontinuous reading meter, and the conditions they ought to satisfy. The three essential parts are: the galvanometer or measuring apparatus, the motive part, and the registering arrangement. That which first of all requires attention is the measuring instrument, and here it is necessary to enquire what it is that is best to measure. On this point we are entirely in agreement with the opinion of M. Hospitalier. The central station supplies electric energy; it is, therefore, the watts that must be measured. On the other hand, every wattmeter becomes of itself a coulomb-meter when the potential is maintained constant, so that this kind of apparatus does not present any further interest, except in the laboratory, for the study of batteries and accumulators, or for the control of batteries of accumulators in central stations. But, in these two cases, the absolute automaticity is superfluous, and the measuring instruments called registering are more appropriate.

Amongst the wattmeters may be distinguished instruments with free swing, and those in which the current only produces a pressure or a couple balanced by an opposing force, and of which the estimation must be made by the putting in action of a force or a couple equal and of opposite direction.

It is this latter type of galvanometer which we prefer for the following reasons:

1. The inertia of the pieces do not come into play; in other words, periodicity is assured.
2. The proportionality is much easier to be obtained.
3. The electro-dynamic or electro-magnetic pulls or couples may be much greater; as there is no appreciable displacement of the moving part, it can be placed in the conditions of maximum effect.

Whatever be the measuring instrument, the accuracy will be, other things being equal, so much the greater as the pulls are greater, and judged from this point of view, the electromagnetic actions are incontestably preferable to the electro-dynamic actions; nevertheless the condition of proportionality and the consideration of alternate currents has led us to make use in our wattmeters of a pressure electro-dynamometer in which we have sought to obtain the maximum pulls.

The arrangement best realising these conditions has long been pointed out by Maxwell; it has since been applied by Sir William Thomson in his last series of measuring instruments. It consists in utilising the pull of two fixed coils upon a flat coil placed parallel and as near as possible to the two first.

The readings of an electro-dynamometer of this type may be made by two different methods: by the action of a movable weight, as is done by M. Marès, or by the torsion or tension of the spring.

A movable mass has its weight invariable, but a counterweight is too sensitive to shocks and trepidations. A spring has the defect of varying with time and with the temperature. But, on the other hand, it is much easier to stretch or twist a spring in a continuous manner than to shift a weight and to push it backward.

If, therefore, on the score of accuracy, the advantages are seen practically to balance each other, on the score of simplicity of the auxiliary mechanism the spring is considerably the better. In fact, the to-and-fro movement which must be given to the movable counterpoise of a Thomson's balance can only be obtained by means of complicated mechanism with alternating movements, where the actions interfere with each other in an awkward manner On the other hand, we have been able to devise an arrangement of readings by the torsion of a spring, the raising of the arm of the balance, and the escapement of cams, in which the whole has a movement always in one direction, so that it is perfectly easy to connect it to the motor shaft.

This leads us to speak of the most important part of the automatic reading meters, the motor, which usually is called upon to furnish, by the constancy of its speed, the equal intervals of time which separate the readings, or rather the equal intervals of time during which the readings take place. In all the meters with which we are acquainted this is done by a clockwork movement wound up by an electric device furnished with a regulator, or by an isochronous motor for discontinuous currents. Now, these arrangements present two distinct disadvantages: the first, the most apparent, is that which results from the electric contacts and the sparking; in spite of all precautions these contacts gradually become dirty and cease to act; moreover, the motive force being essentially intermittent it is necessary to be absolutely certain that it will act in the position last taken by the moving part each time it returns to a state of rest. The second difficulty is the regulation of this motor: none of the simple regulators employed in clockmaking are efficacious, except within very narrow limits, and it is therefore necessary to make the motor act upon the contacts in order to make the number and the duration of the electric impulses vary equal with the variations of the mechanical resistance of the apparatus. Hence new and numerous causes of accident.

(To be continued.)

UNDERGROUND MAINS.—III.

THE CALLENDER-WEBBER SYSTEM.

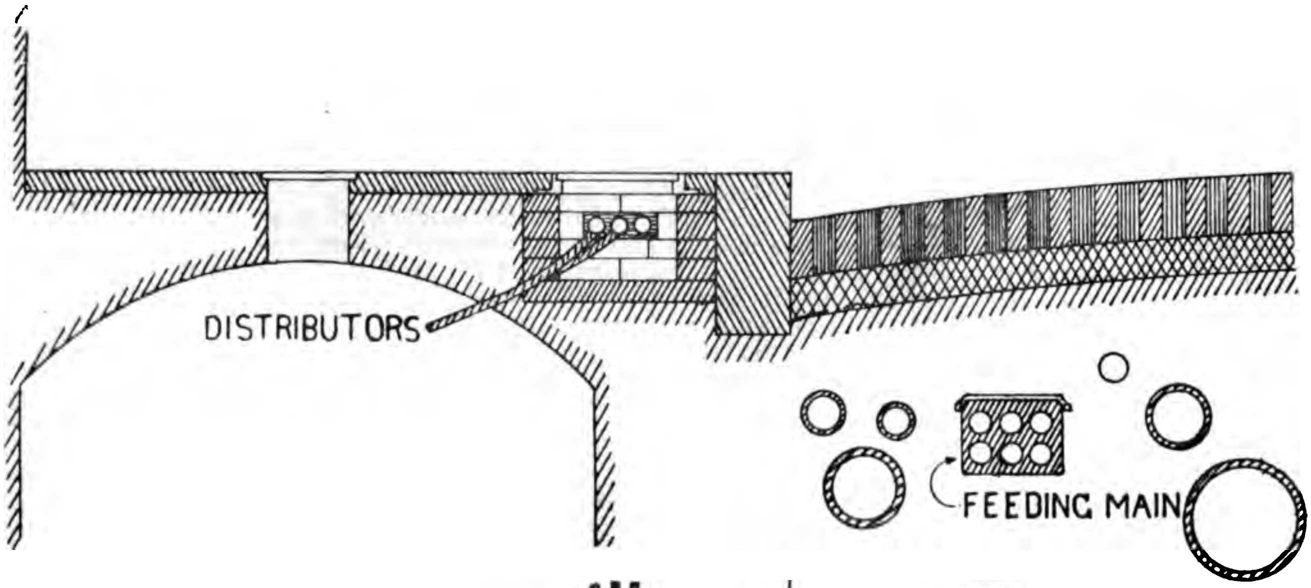
Two systems of underground mains for electric light distribution are carried out by Callender's Bitumen Telegraph and Waterproof Company, Limited, of Leadenhall-street, London. These two systems are known respectively as the Callender-Webber system and the Callender Solid system. In both of these, highly-insulated copper cables are used, laid underground in trenches and protected by bitumen. The method of using the bitumen constitutes the difference between the systems.

In the Callender-Webber system the bitumen is moulded into solid casings having holes throughout the length, and through these the insulated cables are drawn in. This gives facilities for the removal of cables and the substitution, if necessary, of others; and for the provision of spare space to be occupied by other cables as the demand increases, without the necessity for again taking up the streets.

In the Callender Solid system the insulated cables are laid in an iron trough and the whole filled in solid with melted bitumen, the cables being held practically immovable when once laid.

The decision as to which of these two systems is the most suitable depends largely upon conditions of cost and of locality. The solid system will in most cases be the cheaper, if the cable is for a certain stipulated transmission of current which will never be exceeded, or if the demand for current is known or can be estimated closely, so that necessity for alteration or addition is not likely to occur.

FIG. 1.—Callender-Webber System, Descriptive Section of Roadway with Electric Mains amongst Gas and Water Pipes.



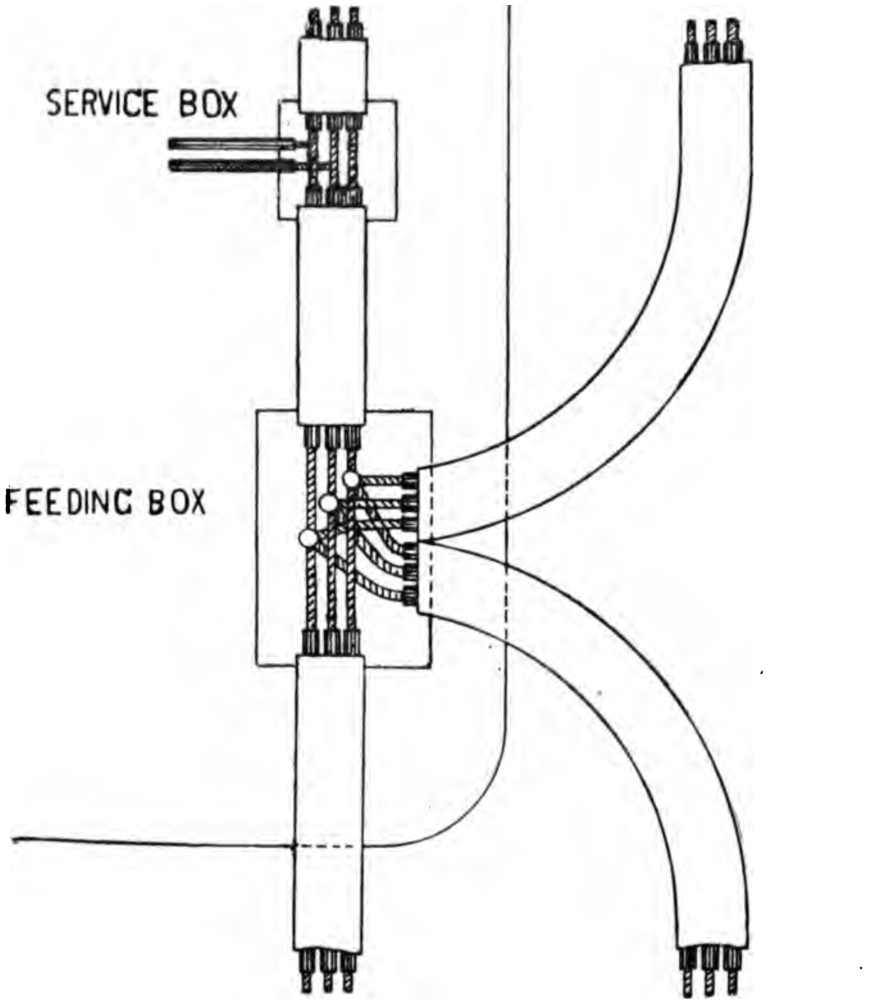


FIG. 2.—Descriptive Plan showing Feeders and Distributing Mains with Service and Feeder Box.

The Callender-Webber system is most suitable for central station work with feeders where the addition of other mains as the demand increases will be certain to be required.

Many large contracts on one or other of these plans have been carried out in all parts of the kingdom, both for central station distribution or for feeders at isolated installations, and also in combination with the various systems of copper mains for use in special situations. The numerous practical details, which are so necessary for the success of any system of distribution, have thus been worked out as the result of actual experience, and the precautions fully learnt which must be taken to ensure high insulation and safe and uninterrupted supply, as well as to assure ease in laying and in the connection of branch or house mains.

We will first describe the Callender-Webber system of underground electric mains, this being the system most applicable to networks of new central stations likely to increase in size. The system is the outcome of the joint inventions of the Callender Company and Major-General Webber, R.E., and its essential distinction lies in providing a solid yet insulating protection to the cables, and a separate way or passage for each cable run.

The general arrangement is well shown in the descriptive section and plan, Figs. 1 and 2, of the roadway, showing six feeding mains, laid under the street among a bewildering array (not at all uncommon in towns) of gas and water pipes and main sewers; with a distributing main on the three-wire system laid under the footpath—feeder boxes and service boxes being constructed flush with the pavement.

Under paved footpaths the depths at which the mains are run need only be sufficient to be just below the higher gas and water service pipes, the concrete foundation of asphalte, or the flagstones of the pavement. In practice, the bottom of the trench is usually 12in. to 18in. below the pavement level, but in cases where space is limited the casings can be run with perfect safety in 3in. or 4in. of depth. This adaptability of the system for limited space, combined with its high mechanical and electrical protection and its power of curving up, or down, or to one side, make it extremely convenient in many places where more rigid systems would be inapplicable.

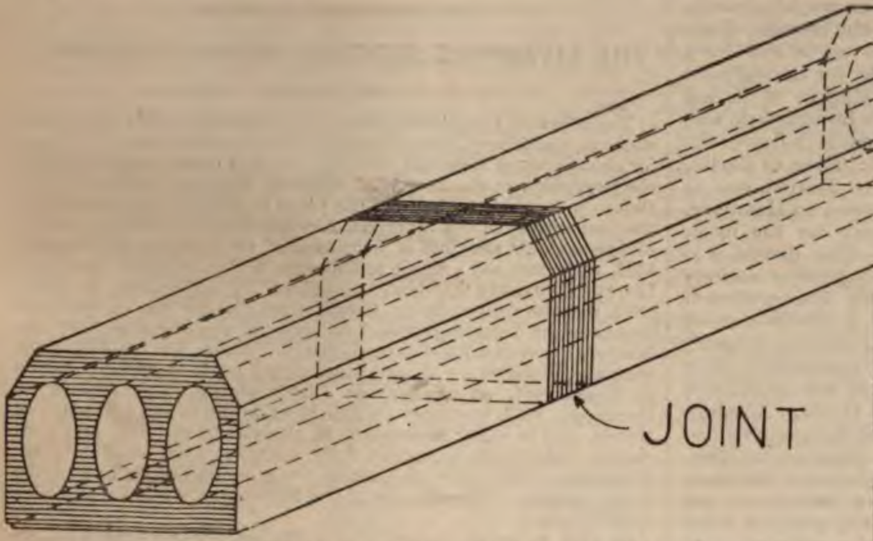

Fig. 3.—Callender-Webber Bitumen Casing showing Joint.

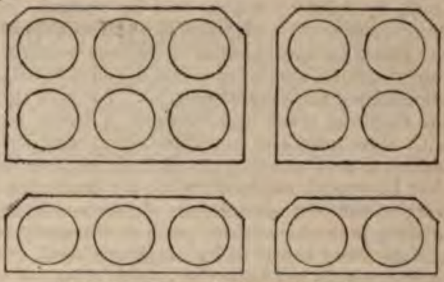

Fig. 4.—General Form of Casing.

The appearance of the bitumen casing is clearly indicated in Fig. 3. It is made in 6ft. lengths of blocks of bitumen concrete, pierced in the manufacture by a varying number of holes or ways. The standard sizes of these cable cases are shown in Fig. 4, and are for two, three, four, or six ways, of either 1½in., 1⅞in., 2⅜in., or 3in. diameter.

The bitumen concrete is composed of natural bitumen (one of the most durable materials known) mixed with sand, and wood fibre, specially treated. The resulting material is tough and strong, with great power of resistance to crushing, breaking, and tensile strains. It is impervious to water, is not affected by gas or acids found in the ground, and is a non-conductor of electricity. It does not expand or contract; and is capable of withstanding, when embedded in the ground, the weights of heavy traffic. It can be made to any shape, and the cases can be bent up or down, or to curve to the right or left on the job in the work of laying, and the process of laying is comparatively simple. When laid each way is a closed passage, completely separated from all the other ways and from earth by a insulating wall of bitumen, and the cables are, therefore, subject to no unfavourable conditions from contact with each other or from deleterious or conducting substances.

When constructing the conduit it is easy to lay the casing with a larger number of holes than is necessary for present requirements, the additional cables being easily drawn in as the demand on the network increases without opening the roadways or disturbing the traffic.

The following table gives the stock sizes, with the size of cable taken.

Sizes of Callender-Webber Casings.

Size.	1½in. ways, taking up to $^{19}/_{14}$ cable.	1⅞in. ways, taking up to $^{19}/_{11}$ or $^{37}/_{14}$.	2⅜in. ways, taking up to $^{61}/_{12}$ cable.	3in. ways, takes over ½in. sect. area, insulated.
2 way	4½in. by 2¾in.	3¼in. by 6in.	4in. by 6¾in.	5in. by 9in.
3 way	6¾in. „ 2¾in.	3¼in. „ 8½in.	4in. „ 9½in.	5in. „ 13in.
4 way	4½in. „ 4½in.	6in. „ 6in.	6¾in. „ 6¾in.	9in. „ 9in.
6 way	4¾in. „ 6¾in.	6in. „ 9in.	7in. „ 9½ir.	9in. „ 13in.

In laying mains underground, whatever the system, it is advisable to carry them as near to the houses as the cellars will admit, and as far as possible the trenches are made under the footpath. When the pavement is of a costly nature and the roadway is of macadam, it is better to run the trenches along the road, but usually the pathway, if not already occupied by telegraph mains or large cellars, is best and cheapest.

In the roadway it is customary to have the trench 3ft. deep. Under an ordinary macadamised road this depth will be quite safe for all ordinary traffic and for temperate climates. If the roadway is concreted as for wood or asphalte paving, it is sufficient to have the mains laid immediately below the level of the concrete.

(*To be continued.*)

TELEGRAPHIC COMMUNICATION BETWEEN ENGLAND AND GERMANY.

The following is a summary of the various changes and improvements in the telegraphic communication between England and Germany which have resulted from the acquisition of the Anglo-Continental cables by the Governments concerned.

For years complaints had been made of delay and irregularity in the arrival of telegrams, especially from Germany, and in the year 1886 Mr. H. C. Fischer, controller of postal telegraphs at St. Martin's-le-Grand, to whose initiative and energy most of the improvements effected are due, was deputed by the Postmaster-General to make a personal enquiry into the working arrangements of the late Submarine Company. He found an almost entire absence of system both in the management and the circulation of the traffic, and an insufficiency of direct lines of communication between England and the principal towns in Germany, especially to Berlin. The result of this paucity of direct wires was that the bulk of the traffic had to be sent by indirect routes, which often led to later telegrams reaching the addressees before others that had been handed in some time previously. There were only 10 wires nominally working direct to the several German towns—namely, two to Berlin, two to Hamburg, one to Frankfort, one to Cologne, one to Bremen, and three to Emden. The communication with Berlin, Hamburg, and Frankfort was wholly inadequate, and only something like 40 per cent. of the traffic could be sent direct, the remainder having to be transmitted by Amsterdam, Brussels and Emden. In the result, although 10 wires were nominally regarded as direct, when Brussels and Amsterdam found that they had more transmitted work on hand than could be disposed of over their own wires, they habitually cut some of the quasi-direct wires passing through their offices and used them to clear off the accumulated traffic for the German offices concerned, and this tended to throw matters in London into further confusion.

There was an entire want of system on the part of the officials of the late Submarine Telegraph Company in regard to the selection of the traffic for indirect despatch, and all that seemed to be done was to get rid of it by forwarding it indiscriminately to one or other of the three transmitting offices mentioned. The effect of this irregular circulation of the traffic was that there was great inequality in the transit times. It was found that three cable conductors were kept "spare" and were not used at all, unless other wires were interrupted—namely, two to Belgium and one to Holland.

Thanks to the cordial co-operation of the German Administration, arrangements were made in advance of the transfer of the cables for working a larger number of direct wires, and for a proper and systematic circulation of the traffic for the different parts of Germany to the offices best able to dispose of it, and from the very first these circulation lists were brought into use. The available cable wires were then allotted as follows, the spare wires being brought into constant use: Four to Berlin, three to Hamburg, two at Frankfort, two to Emden, one to Bremen, one to Cologne, and one from Liverpool to Hamburg. Thus the number of direct wires to Germany for the international traffic was increased from 10 to 14. The diversion of traffic by indirect routes was by mutual arrangement entirely done away with, and when in times of partial interruption of the direct communication it became needful to divert some of the telegrams, special care was taken that the traffic was properly selected for the several places. To meet the representations of the shipping trade at Liverpool, a direct wire was established with Hamburg, and in collaboration with the German Administration a very carefully-studied circulation list was prepared, so that Liverpool might circulate its traffic for Germany to Hamburg to the best advantage. Liverpool then became the transmitting point for various parts of Germany for Manchester and certain other towns in its neighbourhood. The result of these arrangements has been the entire cessation of complaints as to messages having been sent out of their proper order, while complaints of delay have likewise almost ceased.

In order to add to the speed of working the wires in the Norderney cable, repeaters were established at Lowestoft with highly satisfactory results. This has been largely due to the very able manner in which Emden has co-operated in the matter. The directors of the Hamburg office took a special interest in improving the carrying capacity of the faulty wire in the Norderney cable, which, under the Submarine Company, had only given very poor results, some 150, or at most 200, telegrams a day being dealt with. By mutual arrangement picked clerks were appointed to the wire at both ends, with the result that the wire, faulty as it is, now carries more than 400 messages a day. The Bremen wire has of late been worked by the Hughes system, and this has increased its carrying capacity by about 80 per cent., much to the advantage of the service. In concert with the German authorities, the daily hours of working the more important circuits have been extended, so as to provide better for the earlier and later flow of the traffic; and it has also been arranged to remain in direct communication with Frankfort and Cologne throughout the night and on Sundays, instead of leaving the traffic to be transmitted by Brussels, as was formerly done, leading to frequent complaints of delay to Press messages.

A more perfect system of testing the various wires has been mutually concerted between the authorities here and in Germany. The battery power has also been augmented where this was found to be needed, and every effort has been made to put the whole of the apparatus in better working order, with marked results. One very gratifying feature throughout has been the ready and willing co-operation that has been shown at all points in Germany in anything tending to improve the service between the two countries, and it is no doubt to this that much of the present satisfactory state of things is due.

It would perhaps be superfluous to mention in detail all the measures that have been arranged locally in London for the better transaction of the business, for the comfort of the staff, and also for the introduction of a better state of discipline; but much has been done in this direction. For example, under the Submarine Company's *régime* the telegraphists were expected to get their dinners while at work, without relief; but now a dining-room has been provided, and dinner relief afforded, so that there is no break in the continuity of the working as used to be the case, and that, too, during the busier hours of the day. It was the intention of the department to remove the working of the cable wires from the first to the central office at the General Post Office, but owing to the magnitude of the work involved in the transfer and the want of space in the building, it has been found impossible to arrange this up to the present time. Special provision, has, however, now been made for an important branch of the secretary's office to be removed elsewhere to a building which is being constructed for the purpose, and this will afford the necessary space for transferring the cable working to the central office. When this is effected no doubt further improvements in the service will be brought about, as the cable instruments and the instruments communicating with all parts of the United Kingdom will then be under the same roof, and as the tube transit will be done away with and the handlings reduced, it may confidently be expected that the traffic as a whole will materially benefit.

The improved communication, added to the reduction in the tariff, has led to a considerable increase in the number of telegrams, so much so that all the wires are now well filled, and there is no margin whatever for further increase, and in fact any disturbance of the communication at once gives rise to delay.—*Times.*

THE LIVERPOOL ELECTRIC SUPPLY STATIONS.*

BY A. BROMLEY HOLMES, M.I.C.E.

The object of the present paper is to describe briefly the central stations, machinery, and appliances now in operation in Liverpool for the supply of electricity for lighting and other purposes under the provisions of the Liverpool Electric Lighting Order of 1889. Before proceeding to describe the plant in detail a few words as to the past history of the Liverpool Electric Supply Company may be of interest. At the date of formation of the company in January, 1883, there was not a single installation of incandescent lamps in Liverpool, and the first building lighted by this means, in July, 1883, was the restaurant in Eberle-street, where the current was generated by a gas engine and dynamo on the premises, and the light supplied at a fixed annual charge. About the same date the company acquired a site, and constructed its first central station in Rose-street, off Lime-street. This station was started in December, 1883, to supply electric light to the Grand and Adelphi Hotels, and to other consumers in the neighbourhood, and continued without intermission in daily operation from that date till November, 1890, when the mains were connected to one of the newer stations. The capacity of the Rose-street station was under 1,000 lamps.

In 1887 a larger station was built, and commenced work in December of that year in Tithebarn-street. This now forms part of the Highfield-street station. In September, 1888, the Harrington-street station was completed and at work. In 1889 the company's new works, offices, and central station were built in Highfield-street, and the supply of electricity began in October of that year. The company's latest station in Oldham-place commenced work in October, 1890.

The following figures show the rapid extension of electric lighting in Liverpool, the number of lamps of 16 c.p. (or their equivalent) connected with the company's stations being as follows:

On January 1st,	1888	977	16-c.p. lamps.
,,	1889	3,330	,,
,,	1890	6,711	,,
,,	1891	11,750	,,

In the earlier stations separate engines and belt-driven dynamos were used, but these have from time to time been replaced, and the plant is now all of one uniform pattern, each engine and dynamo being combined on one bed-plate. The capacity of the three stations now at work is as follows:

Highfield-street	7,000	lamps, capable of extension to	13,000
Harrington-street ...	4,000	,, ,, ,,	4,000
Oldham-place	4,500	,, ,, ,,	20,000
Total	15,500	Total	37,000

The above figures give the number of 16-c.p. lamps that the machinery is actually capable of supplying direct at one time; and as experience has shown that never more than 75 per cent. of the lamps connected to the supply mains are in use at any one hour, the above plant would have a working margin of 25 per cent. spare power for the number of lamps stated, without taking into account the storage of electricity always available from the accumulators.

The system in use is a direct-current continuous supply at a pressure of 110 volts, all the mains being in simple parallel. It may be convenient to give a detailed description of the plant before describing the method of working.

The boilers are 28ft. long and 7ft. 6in. in diameter, and are made of mild steel. The shell-plates and end-plates are ⅝in. thick, and the ends are strengthened by gusset-stays. The boilers have two flues, 3ft. diameter, tapered to 2ft. 6in. diameter at the back end, and made of mild steel plates $\frac{7}{16}$in. thick, and each flue is fitted with six steel Galloway tubes. The working pressure is from 110lb. to 120lb. per square inch. Of the 10 boilers in use, seven are fitted with Proctor's mechanical stoker, and the remaining three with Viccars's mechanical stoker.

The water supply is taken into the storage tanks from the town mains, and, where practicable, a duplicate service has been carried into the station from a second main. Two feed pumps (or a feed pump and injectors) are provided at each station, and a complete double system of feed pipes, with separate check valves, on each boiler. Feed-water heaters are used, and an arrangement of valves, by which, in case of any breakdown of a heater, the water can be sent direct to the boiler or pumps without passing through the heater. The steam and exhaust pipes are divided into sections, so that any necessary repairs may be effected without stopping the station.

The engines are Willans central-valve compound engines of two sizes, 10 of them being of the I.I. size, with cylinders 14in. and

---

* Paper read at the meeting of the Liverpool Engineering Society, January 21, 1891.

20in. diameter and 9in. stroke, capable of indicating 180 h.p., the remaining three engines being of the G.G. size, with cylinders 10in. and 14in. diameter and 6in. stroke, indicating 60 h.p. All the engines, which are single acting, have two cranks placed on opposite sides of the crankshaft. Each line of pistons is connected to its corresponding crank by a pair of connecting rods, between which work the eccentric and eccentric rod which actuate the valve gear. The eccentric is forged solid on the crank-pin. Piston valves are used, working inside the hollow piston rod which connects the pistons. All the moving parts are in constant compression and subject to a downward thrust.

At the top of the engine is the steam-chest, common to both lines of cylinders. Underneath the steam-chest are the high-pressure cylinders; next, the low-pressure cylinders, and underneath these latter the guide cylinders, which act as air-cushions. A sight-feed lubricator is provided on the steam-chest, and a grease-cup on the top of each line of cylinders for giving a flush of oil if needed. The chamber in which the cranks work is filled with water up to the level of crankshaft. A small proportion of castor-oil is added to the water, and is churned up with it by the movement of the cranks, and effectually lubricates the internal bearings. The governor is fitted directly on to the end of the crankshaft, and actuates an equilibrium throttle-valve fixed at the entrance of the steam-chest. The bed-plate of engine is extended to carry the dynamo. Each engine is fitted with a cylindrical steam separator, which ensures a supply of dry steam.

The dynamos have magnets of the single-inverted horseshoe type, with massive wrought-iron limbs. The armature shafts are coupled directly on to the crankshafts of the engines. The dynamos for the smaller engines give an output of 300 amperes, and an E.M.F. of from 110 to 140 volts, at from 450 to 500 revolutions per minute. The larger dynamos give 900 amperes, and from 115 to 135 volts, at 375 revolutions per minute.

Some of the dynamos are compound wound, but the later patterns are plain shunt wound, and all have a variable resistance attached to them, by which the current through the shunt circuit can be varied and the E.M.F. regulated at will. Two of the dynamos were manufactured by Crompton and Co., and the rest by Siemens Brothers. In the Crompton dynamos the resistance of the armature is ·0028 ohm and of the shunt coils 11 ohms.

The armature is built up of charcoal iron discs keyed directly on to a steel shaft 5¾in. diameter. The core is 36in. long and 18in. diameter. The effort is transmitted from the shaft to the discs by the feather, and from the discs to the winding by means of delta metal driving teeth fixed in holes drilled in the core. The winding consists of 80 turns of pressed stranded bars, measuring ·6in. by ·63in. in section. These bars are made slightly taper, so that they may lie evenly against each other. The armature bars are connected by copper end connections, turned right and left on what is termed the butterfly plan The commutator is made of cast copper sections, and is 9½in. in diameter and 8⅝in. long.

In the Siemens dynamos the resistance of the armature is ·0024 ohm and of the magnet coils six ohms. The armature is constructed with a core of thin sheet-iron discs threaded upon a round steel shaft. The core is insulated and surrounded with 144 insulated bars, each bar consisting of a number of wires stranded together and pressed into a square shape. The insulated bars are connected to one another and to the commutator, as usual in drum armatures. The armature is bound with bands of steel wire to resist the centrifugal force generated whilst revolving.

The accumulators have lead containing boxes, each about 4ft. long by 12in. wide and 13in. deep, supported on heavy wood slabs resting on glass insulators.

The cells are of two kinds, manufactured respectively by the Electric Construction Corporation (formerly known as the Electrical Power Storage Company), and by the Crompton-Howell Electrical Storage Company. The Construction Company's cells are of the well-known L type, E.P.S. pattern, manufactured as follows: The grids are cast in iron chills, the negatives of lead-antimony alloy, and the positives of lead. Both kinds of grids are pasted with red lead mixed into a paste with dilute sulphuric acid, and are then dried and put into the forming tanks. Charging is commenced with a current density of two amperes per positive plate, increasing up to four amperes, the total number of ampere-hours being about 100 each for the positive plates, which are then removed, and their places taken by blind positives, with which the completion of the forming of the negatives, which require about 200 ampere-hours per plate, is continued. When formed, the plates are taken out of the tanks and burned together in sections as required. Each central station cell has three sections of 27 plates each, or 81 plates in all, each plate measuring 9½in. by 9in. by $\frac{3}{16}$in. thick. The maximum safe rate of discharge of the cells is 250 amperes, and the storage capacity about 1,700 ampere-hours at ordinary rates of discharge.

The plates of the Crompton-Howell cells are composed of porous lead, the structure of the plates being entirely crystalline and presenting a large surface to the electrolyte. The active material is formed electrically right through the plate, and does not readily fall away, but adheres firmly to the lead. The plates are mounted on celluloid racks resting on the bottom of the cells, and are kept apart at the top by celluloid combs. The plates are not connected into sections, but the positives of one cell and the negatives of the next are burned on to a common lead bar, supported on insulators between each cell. Each cell has 51 plates 8½in. by 8½in. by ¼in. thick, and may safely be discharged at the rate of 400 amperes, having a storage capacity of 800 ampere-hours when discharged at the normal rate of, say, 200 amperes.

All the distributing mains of the Liverpool Electric Supply Company are laid underground, and have been manufactured and laid by the Callender Company. The conductors are of stranded copper wire, with a conductivity of 98 per cent. The largest feeding mains are composed of 91 No. 9 wires, and have a sectional area of 1·57 square inches. The conductor is covered with two layers of jute yarn, and boiled in refined bitumen. It is next wrapped with parchment tape and covered with a lead casing. The lead is protected by an outside covering of rough jute yarn treated with asphalte and tar. The ordinary feeders are made of 61 No. 11 wires with an area of six of a square inch, and the distributors of 37 No. 13 wires one-quarter of a square inch in area. In both these mains the copper conductor is covered by a solid sheath of bitite or vulcanised bitumen put on under heavy pressure at one operation. This core is next taped and compounded, and finally braided with hemp yarn and passed through a bath of asphalte compound.

The mains are laid in cast-iron troughs ¼in. thick and about 6ft. long, with socket joints. When the troughs are placed in position about ¼in. of refined bitumen in a molten state is run in, and, before setting, spacing bridges of wood are placed in it about 18in. apart. These bridges support the cables and hold them in place, clear of the sides and bottom of the trough and of each other. Bitumen is then run in so as to entirely cover the cables and fill up the iron troughs to within ½in. of the top. The troughs are then finished by a covering of Portland cement concrete about 1in. thick. Strong cast-iron covers are in some cases substituted for the concrete.

The service lines from the distributing mains to the consumers' premises are made of 19 No. 14 wires, insulated and covered with lead pipe, and are run in wood grooved casing, filled in with bitumen and protected with a hard-wood cover strip. The connections of the various lengths of mains to each other, and of the feeders to the distributors, are made by sweating copper lug pieces on to the ends of the cables and by bolting copper connecting bars to the lugs. The distributing mains are jointed in a similar way, the connecting bars being fitted with terminal screws for the attachment of fusible tin strips, to which the service lines are attached.

The connections described above are made in cast-iron joint boxes, measuring inside 16in. by 12in. by 12in., provided with socket pieces to receive the ends of the cast-iron troughs in which the mains are laid. Each box has a strong cast-iron cover held down by a central bronze bolt and crossbar. A watertight joint is secured by means of a soft indiarubber washer between the cover and the box. All joint-boxes are below the level of the pavement, and the surface of the footway is completed by an iron frame and surface plate, by means of which access is afforded to the joint-box. In many cases the surface plates are formed in cement to match the adjoining pavement.

The general arrangement of mains is as follows: A pair of distributing mains are laid under the footways on each side of each street, and are connected together to form a complete distributing network, to which are connected all the service lines to consumers' premises. For convenience in working the network is divided into sections. The supply of current is brought to selected distributing points in this network by heavy feeding mains, which run direct from the generating stations.

The feeding mains are so proportioned relatively to the distance from the station of each distributing point and the number of lamps to be supplied from it that the percentage of loss in pressure in each feeding main may be as nearly as possible the same; in other words, if the lamps were turned on and off uniformly all over the area of supply, a constant pressure might be maintained throughout the network by varying the E.M.F. of the dynamos at central station in exact proportion to the amount of current supplied. As a matter of practice, however, the hours of demand vary in different streets and districts, and it is found necessary not only to vary the station pressure as a whole, but also to regulate the pressure for each set of feeders individually. The following figures will give some idea of the extent of the mains already laid: The district served by the mains extends 1,300 yards (measured straight on map) from Lime-street to bottom of Brunswick-street, 1,000 yards from Old Hall-street to head post office in Canning-place, and 1,550 yards from Highfield-street to top of Bold-street and Wood-street.

The length of frontage along which distributing mains are laid is 9¼ miles. The total length of single cable used throughout the area is 41 miles. Taking a pair of cables to form a main, the lengths of the various classes of mains are as follows:

Feeding mains	10 miles.
Distributing mains	9 miles.
Service lines	1½ miles.
Total	20½ miles.

The weight of copper in the mains is 210 tons. The number of joint-boxes, service boxes, and pressure wire boxes is 630. The number of separate service lines is 275, but many of these serve for the supply of several consumers. Pressure wires are run in specially-laid cast-iron pipes from the various distributing points to the central stations, and are connected to instruments by means of which the actual pressure at each point is indicated to the engineer in charge and is continuously and automatically registered. The main switchboard in each station is fitted with an ammeter and registering pressure indicator for each pair of feeders. These street mains are connected up to massive terminals on the switchboard fitted with safety cut-out strips, which would fuse in the event of any serious short circuit on the main. All the dynamos in a station are arranged to work in parallel on to a pair of positive and negative collecting conductors, and are switched in and out of circuit as the variations in load require.

Each negative feeding main is connected from its cut-out to the station main negative conductor, and each positive feeding main is connected through an ammeter to a main regulating switch, which, when in its normal position, completes contact with the station main positive conductor. By moving the regulating switch it is possible to introduce a number of accumulators, one after another, in the circuit of any desired feeder. These accumulators are arranged in opposition to the dynamo current, and, consequently, the pressure in the feeder, is reduced by two volts for each cell put into circuit by the regulating switch. This at first sight may appear a wasteful method of regulation, but in practice the load is found to rise so uniformly over the whole area of supply that the amount of energy absorbed in regulation is practically unimportant.

The battery of accumulators at each station is capable of supplying 500 lamps at a time, thus enabling the machinery to be stopped at from 10 to 12 o'clock at night and in some cases entirely on Sunday, and also largely in the daytime in summer. The discharge from the accumulators is registered by a recording ammeter. By a special arrangement of dividing the accumulators into sections, devised by the author, they are charged from the dynamos supplying the town at the ordinary working pressure, and by a little care it is in this way possible to so regulate the load on the engines and dynamos as to run them at their highest efficiency.

The very great advantage of this will be appreciated from an inspection of the efficiency diagram of one of the 900 ampere sets of plant, from which it is seen that the electrical efficiency (that is to say, the ratio of the external electrical output of the dynamo to the i.h.p. in the cylinders) is as follows:

At	150	amperes or	1/6	load	50	per cent.
,,	300	,,	1/3	,,	65	,,
,,	600	,,	2/3	,,	79	,,
,,	900	,,	full	,,	86	,,

Continuous tests of the insulation resistance of the mains are made at each station by means of a special apparatus devised by the author for this purpose. If two lamps be connected in series between the positive and negative mains, and a point between the lamps be connected to the earth, the lamps will be found to burn with a variation in brilliancy proportional to the relative insulation resistance of the mains to which each lamp is attached. If two voltmeters be substituted for the lamps, their readings will indicate the same ratio. In the apparatus referred to, a registering voltmeter is used to indicate this ratio continuously. By a suitable arrangement of switches, an ammeter with one terminal connected to earth can be momentarily connected to either main, and the insulation resistance in ohms of the main to which the instrument is not connected is readily arrived at by dividing the station pressure in volts by the number of amperes indicated by the ammeter. For example, if the station pressure be 120 volts, and the ammeter reading three amperes, the resistance of the opposite main would be 40 ohms.

The ammeter used for testing must be accurate at low readings, and therefore is only made to read up to five amperes. In the event of any dead earth fault on the mains the instrument might be destroyed by the sudden rush of current, and to prevent such an accident a magnetic cut-out is placed in series with the ammeter. When more than five amperes passes through the cut-out it breaks contact, leaving in circuit a resistance coil of 25 ohms, so that the current through the instrument, with a station pressure of 125 volts, cannot exceed five amperes. By this contrivance it is possible to measure faults of very low resistance.

The Hookham electric meter used by the company consists of a simple electromotor doing work against the retarding influence of Foucault currents generated in a copper disc rotating between the poles of a permanent magnet. The armature coils are built up on the copper brake disc, and the axis carries a worm which actuates a train of counting gear. The meter is calibrated so that the dial reads directly in Board of Trade units. The speed of rotation (subject to a small frictional error at small loads) is proportional to the current.

Diagrams are exhibited which show the very variable demands made on central station plant at different hours of the day and at various seasons of the year. From these it will be seen that the number of Board of Trade units used per lamp per month varies from 6·3 units in January to 1·2 units in June. Also, that in December the output reaches 4,060 amperes, whilst in June it does not exceed 500 amperes.

This paper has been limited to the description of the central station plant and appliances of the Liverpool Electric Supply Company, and to the method of working simply from an engineering point of view, and no attempt has been made to deal with commercial details either of capital expenditure of working costs, which may be more usefully brought before this society, after longer experience, at a future date.

ELECTRIC LOCK AND BLOCK SIGNALLING.

On the 14th instant, as we mentioned in a recent note, Mr. Spagnoletti, M.I.C.E., read a paper before the Inventors' Institute on the "Electric Locking and Block System," as applied on the City and South London (Electric) Railway.

Mr. Spagnoletti, after a concise description of the construction of the line, fully explained and described the working of the electric locking system as applied to both double and single lines. The lever of the starting signal is always kept locked to "danger," and before a signalman can possibly pull over and lower the signal arm for a train to leave his station he must send a bell-code to the next station in advance to unlock his lever. This can only be done by the man at the station in advance sending a current of electricity by an instrument in his signal-box, and the act of sending this current locks up his instrument so that he cannot possibly send another until the train arrives at his station and passes the clearing point, when it passes over a contact-maker (a treadle fixed beneath the rail) and resets his instrument so that it can be worked again for a second train, but not until the first train has arrived and the section is clear.

When the signal arm has been unlocked and lowered for a train to proceed, after its departure it must be replaced to "danger," and it cannot be lowered a second time until the lever has been again unlocked from the station in advance, and the signalman at the station in advance cannot again unlock until the train occupying the section has cleared it and reset his instrument to enable him to do so. This piece of automatic working, which gives no signal itself, forms a thorough check upon the signalman, and prevents him making any mistake from any misapprehensions he may have in his mind. It simply resets his instrument to enable him to work it again, and checks him if he should attempt to work it at a time when he ought not to do so before the section is clear. When the starting signal lever has been lowered for a train to leave it must be put back again, or the signalman cannot take the lock off for a following train coming from the station in the rear.

In working single lines, when taking the lock off at either end from the opposite end of the single line section for a train to proceed, the act of releasing the lock at the other end locks up the instrument and severs the wire which conveys the current to the lock in either direction, so that it is impossible to take the lock off again at either end until the train occupying the section has arrived at the proper place in whichever direction it is going and resets the instrument and re-establishes the circuit. When the lock has been taken off, by the station in advance, for a train to proceed over the section, and the train from any cause should not proceed, the signalman is compelled to move his lever and lock it before he can take the lock off at the other end for a train coming in the opposite direction. Mr. Spagnoletti also pointed out that in working junctions one instrument only is required, as by means of a switch any number of line wires connecting the next stations on the various branches can be joined to this one instrument without affecting the safety of the working. In crossing trains from one road to the other he explained that when the levers affecting cross-over roads were unlocked trains could not be allowed to approach the station on either the up and down line, and *vice versâ*. He pointed out that a section might be divided into two sections and yet be worked by the same signalman, by having an intermediate signal locked from the same signal-box, so that the one signalman could work both sections, first taking off the lock at the station in the rear for a train to proceed to the intermediate signal fixed at a certain point, which signal lever can only be unlocked by himself when the second section is clear, thus saving the expense of an extra signal station and staff to work it.

On local lines where trains stop at every station there is no need for fogmen in foggy weather, because no train enters a section until it is quite clear, and the train itself controls the working of the section. Should any derangement occur to the instrument in working, the safety of the system is not affected, neither is any delay to the traffic caused because the derangement locks everything up on the side of safety, and the instrument can be worked by hand as well as by the treadle under the guidance of the inspector or other authorised person when any derangement may occur. This system does not relieve the signalman from any of his present responsibilities; it simply checks him from doing wrong if he should attempt to do so, and prevents him from working the signals when he should not do so. This system is at work on many lines and is giving every satisfaction. It is a system which will, no doubt, grow as it becomes better known and understood, and it is one which evidently will greatly add to the safety of railway working.

Diagrams and working instruments for two stations and intermediate section of line were exhibited and explained.

PHYSICAL SOCIETY.—Jan. 16, 1891.

Prof. W. E. Ayrton, F.R.S., President, in the chair.

The thanks of the meeting were unanimously accorded to the Maxwell Memorial Committee for presenting to the society a copy of Maxwell's scientific papers.

Prof. G. M. Minchin, M.A., read a paper on "**Photo-electricity.**" His experiments on the subject were commenced in 1877 in attempting to produce a photographic image of a distant object. The result sought for has not hitherto been attained, but the experiments have led to the discovery of many interesting phenomena. Some of these were shown to the meeting. Electric currents are produced by the action of light on silver plates coated with collodion or gelatine, emulsions of bromide, chloride, iodide, and other silver salts, or with eosine, fluorescine, and other aniline dyes, when the plates are immersed in a suitable liquid, and one plate illuminated whilst the other is screened. The directions of the currents depend on the materials employed, and the blue end of the spectrum is most effective. Currents have a photographic effect on the plates, and this action is strictly confined to the parts through which the current has passed. Comparatively strong currents were obtained from plates with eosine and gelatine. A curious reversal was observed with some cells, the exposed plate first being positive to the screened one, and almost immediately afterwards became negative. On shutting off the light a transient increase of current resulted, and afterwards disappears gradually. M. Becquerel, who has studied the action of silver plates coated with bromide, etc., concludes that the nature of the exposed plate (whether positive or negative) depends on the thickness of the surface layer. The E.M.F. of such cells rarely exceeds $\frac{1}{20}$th of a volt. Uncleaned tinfoil plates in common tap water give a current when one is exposed to light and the other screened. Cleaning the plates destroys the effect. In nearly every case the exposed plate was first positive, and after a time became negative, and by exposing various parts of a plate (some portions of which had been previously exposed) the currents could be varied in direction at will. These peculiarities may explain the known divergence of tin from Volta's law. The phenomena have also been studied by aid of the electrometer. Tin foil obtained from tobacco packages was found to be very sensitive to light. One side of such foil is dull and the other bright. By pasting slips of it on opposite sides of a glass plate, so that dissimilar sides were outermost, and immersing them in alcohol, a cell giving an E.M.F. of $\frac{1}{16}$ volt, when the dull side was exposed to light, was obtained. The addition of any salt to the liquid with a view to diminishing the resistance, invariably reduced the E.M.F. Experiment showed that the alcohols were by far the best liquids to use with tin plates. A process for producing very sensitive tin plates was described, which apparently results in the formation of white oxide of tin on the surface of the foil. With one such plate and another unsensitised plate the best results have been obtained by immersing them in methyl alcohol prepared from oil of winter green. From experiments on the variation of E.M.F. with the intensity of light it was found that the square of the E.M.F. is proportional to the intensity. Some tin cells behave in a very peculiar manner, for it often happens that a good cell will exhibit no E.M.F. after being kept a few days. A slight impulse or tap given to the cell or its support restores the sensitiveness. Another impulse makes the cell unsensitive, and these effects can be repeated indefinitely. Such cells the author calls "impulsion cells," and some were exhibited at the meeting. The sensitised plate of one of these cells had different properties at its two ends, for impulses had no effect on the nature of the lower end, but changed the upper end from positive to negative and *vice versâ*. Electromagnetic impulses, such as produced by sparks, are capable of altering cells from the unsensitive to the sensitive state, but fail to produce the reverse effect; a Hertz oscillator restored the sensitive state in a cell placed at a distance of 81ft. away. The "impulsion effects" can be got rid of by renewing the alcohol on several successive days. During last year the author made some selenium cells by spreading the melted substance on metal plates, and immersing them in liquids together with an uncoated plate. Of the various metals and liquids tried, aluminium and acetone gave the best effects. The process of forming these "seleno-aluminium cells" was described. One of their peculiarities is that they are nearly equally sensitive to rays of all colours; and when exposed to strong light may give an E.M.F. of $\frac{1}{2}$ to $\frac{2}{3}$ of a volt, the sensitised plate being negative. An arrangement of 50 cells in series, with an electrometer, was exhibited, whereby the E.M.F. generated by light falling on the cells could be caused to ring a bell, light or extinguish electric lamps, etc. In conclusion, the author pointed out the possible applications of photo-electricity to photometry, tele-photography, and the utilisation of solar energy. At the request of the President, Prof. Minchin promised to show the experiments on Feb. 13, on which date the discussion on the paper is to take place.

Prof. F. R. Barrell, B.A., exhibited and described a lecture-room apparatus for determining the acceleration due to gravity. A number of iron balls are allowed to fall through a certain height in such a way that one starts off when its predecessor arrives at its destination. From the time occupied by all the balls, the time for one can be found, and, knowing the distance traversed, "g" can be determined. The apparatus consists of two electromagnets joined in series with a battery and key, together with a ball-feeding device. One of the magnets is vertically over the key and serves to catch the balls as they emerge from the feeding tube, whilst the other magnet actuates a kind of slide for supplying successive balls. When one ball falls on the key it breaks circuit, and thus causes the first mentioned to let go its ball. The key then springs up again, thus making circuit; the feeding magnet then supplies another ball, which is caught by the holding magnet until the falling ball reaches the key, and the operations are repeated. Fairly accurate results can be obtained by the apparatus.

Sir John Conroy's paper "On the Change in the Absorption Spectrum of Cobalt Glass by Heat," was postponed.

LEGAL INTELLIGENCE.

BERRY v. CHALLIS.

Claim by Electrical Engineers.

In the Westminster County Court recently, the case of Berry *v.* Challis came on for hearing before His Honour Judge Bayley. The proceedings were brought at the instance of the plaintiffs, who are a firm of electrical engineers carying on business in Gerard-street, Soho, and the claim was for £26 odd for work done and materials supplied in fixing up two arc lamps outside the defendant's premises at the corner of Coventry-street.

Mr. Cooper Wylde was counsel for the plaintiff, and Mr. Tatlock appeared on behalf of the defendant.

The defendant admitted a portion of the claim, and paid the money into court, thus reducing the amount in dispute to £7. 18s. 3d.

In opening the plaintiff's case, **Mr. Cooper Wylde** said that in May of last year the defendant communicated with the plaintiff with a view to having two electric lamps fitted up outside his premises, which were situate at the corner of Coventry-street and Rupert-street. Negotiations were entered into between the parties, and ultimately the plaintiff received definite instructions to proceed with the work. In due course the lamps were completed, and the defendant's premises were lighted by electricity. They had not, however, been up long before the defendant intimated that their position did not please him, and he must have them fixed considerably higher up. A good deal of the work which had been done had consequently to be done over again, and new supports had to be provided, thus entailing extra expense, and it was in respect of these and other items that the present dispute had arisen. The plaintiff contended that as it was no fault of theirs that the work had to be done over again, they were justified in charging it to the defendant.

The plaintiff was called, and said that he had a conversation with the defendant as to the proposed alterations, and told him that if it was to be done it must be at his expense, to which suggestion he agreed. He was quite sure that the work was properly and efficiently done by his men, and if there was any difficulty with the light it was not through any fault of his. The materials supplied for the work were of the very best description. One of the reasons why the light failed was, that the cellar from which it was turned on and off was damp, and it was a well-known fact that wet or damp was a deadly enemy to electricity.

Several other witnesses were called and gave evidence as to the manner in which the work was done.

For the defence, it was contended that the amount which had been paid into court was all the defendant was entitled to pay, as a good deal of the work which was claimed for was rendered necessary not through any fault of the defendant, but in consequence of the plaintiff's faulty workmanship.

After a long hearing, his **Honour** came to the conclusion that the money which had been paid into court was sufficient, and that being so, entered judgment for the defendant.

UNITED TELEPHONE COMPANY, LIMITED, v. ANDREW ERSKINE MUIRHEAD.

In the Edinburgh Court of Sessions on Friday, before Lord Wellwood, the United Telephone Company, Limited, and the National Telephone Company, Limited, London, sued Andrew Erskine Muirhead, merchant, Cart Forge, Crossmyloof, Glasgow, to have the defendant interdicted from infringing the letters patent, dated July, 1877, granted to Thomas Alva Edison, of Menlo Park, New Jersey, U.S.A., for the invention of "improvements in instruments for controlling by sound the transmission of electric currents, and the production of corresponding sounds at a distance," and from making, using, and exercising or vending, during the continuance of the letters patent, the invention described therein. £500 is sought in name of damages for the alleged infringement, and delivery is also sought of all instruments possessed or controlled by the pursuer, including the "Ader" transmitters, which are made in infringement of the letters patent, and also all instruments made according to the manner described in the letters patent dated December, 1876, granted to William Morgan, of Brandon and Morgan-Brown, engineers, London and Paris, for the invention of "improvements in electric telephony (transmitting or causing sounds for telegraphing messages) and telephonic apparatus," a communication from abroad by Alexander Graham Bell, of Boston University, U.S.A. The letters patent in question are vested in the United Telephone Company, subject to certain rights to the National Telephone Company. The pursuers say that the defender has been violating their letters patent by erecting telephone transmitters and receivers of the "Ader" type. The defender says that the statements of the pursuers, so far as material, are unfounded in fact, and that he ought to be assoilzied.

The record was closed, and the case sent to the Procedure Roll.

COMPANIES' MEETINGS.

ELMORE'S AUSTRO-HUNGARIAN COPPER DEPOSITING COMPANY.

The first general meeting of this Company was held at the Cannon-street Hotel on Friday, 23rd inst., Mr. James Rock, M.P., presiding, in the unavoidable absence of the chairman, Sir John Morris.

With regard to what had been done since the formation of the Company, the **Chairman** said that their General Manager and Mr. Stepney Rawson had been in Austro-Hungary looking for sites for works, with the result that they had provisionally decided upon a site in a good position as regarded raw material and transport. They had acquired the German patents for the Elmore process, and they were in negotiations there for a large manufactory, having available water power to the extent of 550 h.p., besides the steam power on the premises. Mr. Elmore was now in Germany completing the arrangements. They had allotted 50,000 shares, which were very largely paid up. They were allotted to about 580 shareholders.

Resolutions were then proposed from the chair and carried unanimously: (1) Altering the name of the Company to Elmore's

German and Austro-Hungarian Metal Company, Limited, and (2) and (3) making certain alterations in the articles of association required by the Stock Exchange before granting a special settlement.

PROVISIONAL PATENTS, 1891.

JANUARY 19.

912. **Improvements in automatic electric locking gear for controlling signals on railways.** David Richards, 44, Wern-road, Landore, near Swansea.

937. **Improvements to securely attach electrical wires to ceiling roses.** Elijah Atkins and Edward Elijah Atkins, 19, Villa-grove, Handsworth, near Birmingham.

JANUARY 20.

965. **Improved therapeutic magneto-electric mechanisms.** Henry Harington Leigh, 22, Southampton-buildings, London. (Joseph Brown Gardiner, United States). (Complete specification.)

980. **Improved electric signals for railways.** William Walker, Matthew Walker, John Sansom, and Arthur Cole, 39, Guildford-street, Luton, Bedfordshire.

984. **Improvements in telegraphic transmitting apparatus.** Richard Theiler and George Keith Buller Elphinstone, 86, Canonbury-road, London.

991. **An improved electric percussive rock drill.** Albion Thomas Snell, 52, Chancery-lane, London.

1004. **An improved indicator for electric potentials.** Sir Wm. Thomson, 154, St. Vincent-street, Glasgow.

1007. **Apparatus for separating ores and metals by the aid of electricity.** Erminio Ferraris, 89, Chancery-lane, London. (Complete specification.)

1035. **Improvements in primary batteries.** Samuel William Maquay, 55, Chancery-lane, London.

1046. **Apparatus for prepaid telephonic messages.** Robert Howe Gould and Theodor Gottschalk, 46, Lincoln's-inn-fields, London.

1049. **Improvements in the manufacture of dynamo-electric machines.** Sebastian Ziani de Ferranti, 24, Southampton-buildings, London.

1050. **Improved means for distributing electrical energy.** Sebastian Ziani de Ferranti, 24, Southampton-buildings, London.

1051. **Improvements in electrical transformers or converters, and in their manufacture, partly applicable to the manufacture and testing of dynamo and other insulated conductor coils and armatures.** Sebastian Ziani de Ferranti, 24, Southampton-buildings, London.

1053. **Improved method for testing the electrical firing gear of ordnance.** Andrew Noble and Edward William Lloyd, 24, Southampton-buildings, London.

JANUARY 21.

1066. **Improvements in electric blank heaters for forging machines.** George Dexter Burton and Edwin Elliott Angell, 52, Chancery-lane, London. (Complete specification.)

1084. **Automatic throwback for electric indicators.** William Howard Jackson, 3, Brabant-court, Philpot-lane, London.

1114. **Improvements in electric railways and in apparatus for the propulsion of vehicles by electricity.** Albert Churchward, 45, Southampton-buildings, London. (Archibald J. Robertson, United States.) (Complete specification.)

1118. **Improvements in folding lamp shades for gas and electric lamps.** Oliver Imray, 28, Southampton-buildings, London. (Ludwig von Orth and E. Breslauer, Germany.)

1122. **Improvements in or connected with incandescent electric lamps.** Abraham Denby Raine, Norfolk House, Norfolk-street, London.

1138. **An improved guard for incandescent electric light globes.** William Henry Munns, 55, Chancery-lane, London. (Joseph Mino and W. D. Wastfield, United States.)

JANUARY 22.

1173. **Improvements in appliances for the transmission of electric energy.** Sir William Thomson, 154, St. Vincent-street, Glasgow.

1175. **Improved safety ventilating self-lighting gas and electric battens for lighting up theatres and other public buildings.** Joseph Tollerton, 8, Quality-court, London.

1176. **Improvements in brush-holders for dynamo-electric machines and electric motors.** Francis Murray Newton and Tom Hawkins, 46, Lincoln's-inn-fields, London.

1185. **Improvements in cable relays.** Richard Theiler and George Keith Buller Elphinstone, 86, Canonbury-road, London.

1192. **Means and apparatus for propelling boats and rafts on waterways by means of electrical energy.** Otto Büsser, 28, Southampton-buildings, London.

1200. **Electric contact for locks.** William Henry Colson, 37, Chancery-lane, London.

1202. **Improvements in electric clocks.** Marius Devries, 4, South-street, Finsbury.

JANUARY 23.

1250. **Improvements in globe holders for electric and other lighting fittings.** Elijah Atkins and Walter Atkins, 12, Cherry-street, Birmingham.

1251. **Improvements in electrical switches.** Elijah Atkins and Walter Atkins, 12, Cherry-street, Birmingham.

1279. **Improvements in and relating to electric signals for railways.** Edgar Clarence Wiley, James Alexander Dickey, and Napoleon Breedlove Ainesworth, 77, Chancery-lane, London. (Complete specification.)

JANUARY 24.

1329. **An improved electrical heating and cooking apparatus.** William Henry Munns, 55, Chancery-lane, London. (Charles Talmage, United States.)

1332. **An improved insulator for electric wires.** William Henry Munns, 55, Chancery-lane, London. (Fidel Miro, West Indies.)

1339. **Improvements in alternating current electric clocks.** Ernest de Pass, 78, Fleet-street, London. (Heinrich Christian Spohr, Germany.)

1350. **An improved galvanic belt.** Charles Andrews, 175, Wardour-street, London.

1359. **Improvements in or relating to electrical fire signals.** Alfred Julius Boult, 323, High Holborn, London. (Charles Dixon and — Fouler, France.)

SPECIFICATIONS PUBLISHED.

1889.

20652. **Incandescence electric lamps.** Edmundson and Clarke. 6d.

1890.

3732. **Electro locomotives.** Hopkinson. 6d.

18491. **Dynamo electric machines.** Kennedy. 8d.

19406. **Electric current meters.** Hartmann and Braun. 6d.

CITY NOTES.

Brazilian Submarine Telegraphs.—The traffic receipts of the Brazilian Submarine Telegraph Company, Limited, for the week ended January 23 were £6,367, and those of the Western and Brazilian Telegraph Company, Limited, £5,195.

Woodhouse and Rawson United, Limited.—The resolution which was passed at the extraordinary general meeting on January 9, increasing the capital of the Company to £550,000, was unanimously confirmed at a meeting held this week.

Western Union Telegraphs.—The numbers are announced of seven bonds of £200 each and six bonds of £100 each of the Western Union Telegraph Company 6 per cent. sterling loan, to be paid off on and after March 2, by Messrs. Morton, Rose, and Co., Bartholomew-lane, E.C.

Electricity Supply Company for Spain.—The Electricity Supply Company for Spain, Limited, invite applications to Messrs. Martin and Co. for an issue of £75,000 in 6 per cent. mortgage debentures at 98, which will be secured by a first mortgage (in favour of trustees) on the Company's freehold land, buildings, and machinery, and by a floating charge on all the Company's other property.

Anglo-American Telegraph Company.—The report of the Directors of this Company shows that the total receipts from July 1st to December 31st, 1890, including £2,793 brought forward, are estimated at £161,986. This amount, however, is subject to revision, as the lawsuit between this Company and the Paris and New York Telegraph Company is still pending before the Council of State. The traffic receipts show an increase of £3,027, and the total expenses, including repair of cables, etc., amounted to £56,142. Interim dividends of 15s. per cent. on the ordinary and £1. 10s. per cent. on the preferred stock were paid on the 1st of November last, absorbing £52,500, leaving a balance of £53,344, out of which the Directors recommend final dividends of 15s. per cent. on the ordinary and £1. 10s. per cent. on the preferred stock, making a total distribution for the year ended December 31st of £2. 17s. 6d. per cent. on the ordinary and £5. 15s. per cent. on the preferred stock, leaving £844 to be carried forward.

COMPANIES' STOCK AND SHARE LIST.

NOTES.

Death of Otto.—The death is announced from Cologne of Herr Otto, the original inventor of the celebrated gas engine of that name.

Glasgow Theatre.—In the redecoration of the Glasgow Gaiety Theatre, just reopened, electricity has been employed for illumination.

Barnsley.—The Town Council have received tenders for their electric light station, and have adjourned the consideration of them to the next meeting.

Dublin Railway.—There is now a continuous connection of Dublin with the Kingstown pier. The carriages are of the best quality and are lighted by electricity.

Berlin Theatres.—The police have requested every theatre and place of entertainment in Berlin capable of containing more than 800 persons, to be lighted by electric light.

Consulting Engineer.—Mr. Reginald P. Wilson, late of the London Electric Supply Corporation, has taken offices as consulting engineer at 3, Princes-mansions, Victoria-street.

Folkestone.—Mr. Councillor Logan has given notice that at the next meeting of the Corporation of Folkestone he will revive the question of lighting the town streets with electricity.

Institution. — The discussion on Major-General Webber's paper on "The Distribution of Electricity, with especial reference to the Chelsea System," took place before the Institution last night.

Ripon.—The Water Supply Committee of Ripon have had under consideration an agreement with the Marquis of Ripon for the lease of water power for the purpose of providing Studley Royal with the electric light.

Honours.—The Queen has given orders for the promotion of Sir Frederick Abel, C.B., President of the Committee of Explosives, War Department, to the dignity of a Knight Commander of the Order of the Bath (Civil Division).

The Brush Company. — Mr. E. Garcke, formerly manager and secretary of the Brush Electrical Engineering Company, Limited, has been appointed a managing director of that company, and Mr. B. Broadhurst succeeds him as secretary.

Bromley.—The South-Eastern Railway Company have notified their intention of opposing in the House of Parliament the provisional order passed by the Board of Trade on the application of the Bromley Local Board for electric lighting powers.

Utilising the Swiss Rivers.—The Municipality of Zurich have had before them the request of a syndicate for a grant of permission to utilise the River Reuss, which they propose to employ for the transmission of power electrically to the surrounding districts.

Duties on Chemicals.—The Paris General Customs Committee on Feb. 2 adopted a new scale of duties upon chemical products. Sulphuric acid will be exempt, and nitrate of potash will pay two and three francs per 100 kilos, and caustic soda six and eight francs.

Electric Photography.—M. Lafayette, photographer, of Glasgow, is reputed to have a 10,000-c.p. arc lamp for use in dark weather, and at night, mounted on a portable stand with flexible cables. The current is supplied from 61 storage cells charged by a gas engine and dynamo in an adjoining room.

Erith.—The Erith Local Board have appointed a committee to consider the question of the future lighting of the area over which they have control, and as both gas and oil lighting have been tried and voted failures in this locality, special consideration will be given to the desirability of adopting the electric light.

Electric Standards. — The Electrical Standards Committee held their second meeting at the Board of Trade on Saturday last. The following members were present—viz., Mr. Courtenay Boyle, Major Cardew, Mr. Preece, Mr. Graves, Lord Rayleigh, Sir W. Thomson, Prof. Carey Foster, and Dr. Hopkinson.

The Postal Telegraphs.—On February 5th, 1870, the undertakings known as the United Kingdom, the Electric, and British and Magnetic Telegraph Companies were transferred to the Government. Yesterday (Thursday), therefore, the Postal Telegraph Department celebrated its twenty-first birthday, or, in other words, came of age.

Indian Telegraphs.—Something like 1,800 miles of wire were added to the great network of Indian telegraphic communication last year, and the department reports a profit on the operations of the year amounting to about 21 lakhs of rupees. An analysis of the returns show that while the inland telegrams increase rapidly in number the messages are more and more curtailed.

Chatham.—In consideration of the company having already spent £10,000 in supplying the electric light, the Chatham Local Board of Health have resolved to recommend the Board of Trade to accede to an application of the Chatham, Rochester, etc., Electric Lighting Company to be released from the engagement of depositing £500 as a guarantee for the fulfilment of the provisional order.

Staircase Lighting.—In several houses in Berlin let in flats, an ingenious arrangment of temporary electric lighting has been installed, for the advantage of late comers who enter after the extinction of the light in the hall. When the outer door is opened a light starts up and remains alight while the tenant is below, and as he mounts, the various flights of stairs are illuminated one after the other.

Ship Lighting.—Messrs. David J. Dunlop and Co., engineers and shipbuilders, Inch Works, Port Glasgow, have launched from their yard a handsomely modelled awning-deck passenger steel screw steamer built by them to the order of Sobrinos de Herrara, of Havana, for their coasting service between Havana and Porto Rico. The vessel will be fitted throughout with electric light, including a powerful search-light.

The North Riding County Council have resolved: "That it be an instruction to the Highways Committee that, when applications are received to erect either telegraph or telephone posts by the side of their main roads, the committee inform the applicants that the County Council have no power to grant such permission, but that if such posts are erected they will be at the risk of the applicants."

Personal.—Mr. Orlo. V. Thomas, A.I.E.E., has resigned the position of managing electrical engineer to the Taunton Electric Lighting Company, Limited, and has been appointed by the Crown Agents for the Colonies to take charge of the installation at Singapore. The electrical staff of the company presented Mr. Thomas on his leaving them with a photograph of themselves in a handsome frame of oak, bearing an inscribed silver shield.

House Electricians' Handbook.—We received some time back an illustrated handbook in German issued by the

Mix and Genest Company, containing a vast amount of information upon subjects connected with house bells, telegraphs, telephones, lightning conductors, and all other electric arrangements for domestic use. The necessity for issuing a second edition within two months is, perhaps, the best proof of the usefulness of this little work.

Electric Light Installation near Ascot.—Sunningdale Park, near Ascot, which has recently been acquired by Major Joicey, is to be electrically lighted throughout. It is estimated that about 350 lamps will be required to light the house and stables, and the generating plant will comprise two Cornish boilers, and two Parsons steam turbine-dynamo machines of the new improved type. The installation is being arranged by Mr. A. A. Campbell Swinton.

Old Students' Paper.—A paper will be read before the Old Students' Association, at Finsbury College, Leonard-street, on Wednesday, February 18, at eight o'clock, by Duncan Pearce, member (hon. treasurer), entitled "From College to Factory," being the contributor's experience in the so-called department of theory and practice. It will be divided into the heads (a) Present defections of both from an ideal; and (b) Suggestion for making up the deficiencies, with the object of making manufacture a profit and pleasure.

The s.s. "Panama."—The fine screw steamer "Panama" has just sailed from the Tyne for Cadiz. Messrs. Wigham Richardson and Co., of Low Walker, have entirely reconstructed and fitted her as a first-class mail steamer. The ceiling is divided into panels and decorated in white and gold with a soft French tint. The vessel is fitted with the electric light. The ladies' boudoir is finished in a very artistic manner, the fringes and velvet being of old gold. The state and other rooms are in keeping with the other fine furnishings.

Manchester.—In the Manchester City Council on Wednesday, Mr. J. Brooks stated that the Electric Lighting Sub-committee were making progress in reference to the lighting of a prescribed area with the electric light, and very shortly they would submit a report as to the manner in which the work should be done. At a later stage of the proceedings, the Mayor intimated that arrangements were in progress for putting the electric light throughout the Town Hall. When that was done, the ventilation, he thought, would be greatly improved.

Leeds Tramway.—Leeds is to have its electric tramway on the Roundhay line begun very shortly. The Highways Committee have reported that steps were taken to hasten the accomplishment of the scheme. It was stated that the Thomson-Houston Company, who are to work the service, were doing all they could to expedite matters. They had, it was reported, been before the Board of Trade, who had agreed to everything, with the exception of a few minor details, and when these had been disposed of the work was to be commenced forthwith.

Sites of Central Station.—According to the *Elektrotechnische Zeitschrift*, the simplest method of determining the best site for a central station will be to find the centre of gravity of the system, taking the values of various points in the area as proportionate to the density of current to be supplied at these points, in which case the total weight of copper in the feeders will be at the minimum. This calculation will, however, have to be modified when the considerations of cost of site and rent and, it may be, cost of cartage of fuel and so forth, are taken into account.

Leeds.—On Friday, at a meeting of the Sub-Parliamentary Committee (Electric Lighting) of the Leeds County Council, the question of the three applications which have been made for provisional orders to supply electric light in the town by private companies was discussed at considerable length. The town clerk explained the legal position of the Corporation, and the borough engineer gave some further information on the subject. Ultimately, any decision was postponed, pending which Mr. Hewson, the borough engineer, will get together further information.

Canada.—The attention of certain manufacturers of electrical apparatus might be very well turned to Canada. From recent information we have received from this great colony we hear that nearly every town of any pretension has its public and private lighting, and incandescent lamps are common in most houses of the well-to-do classes. But there is a great want of pretty and artistic fittings; very little but the most common-place and ugly fixtures are to be obtained as a rule. This may be a hint that our readers may be able to take up, and rectify so great a lack of beauty in fittings.

Edinburgh. — The Corporation of Edinburgh have replied to certain objections raised by the Corporation of Leith in the form of a parliamentary paper. With the view of meeting the objections stated for the Corporation of Leith, the Corporation of Edinburgh are ready to consent to a provision being inserted that the Gas Commissioners should not be entitled to accept any transfer of the powers of the Corporation under the order, except by a vote of at least three-fourths of the Gas Commissioners, and except with consent (1) of the Corporation of Edinburgh and (2) of the Corporation of Leith.

Steam v. Electricity.—An electric car at Brockton, Massachusetts, the other day came into collision with a railway train on a level crossing. The car was overthrown, and six women who were riding in it were injured, two very seriously. Stephenson's old saying "Bad for the coo" (or car) still holds good. It would have been the other way, however, if Mr. Weems's 400 mile an hour car had been the electric representative in the contest. We trust, however, that as electric traction increases, a great deal more care will be taken at American level crossings to avoid accidents between the two rivals.

Electrical Transmission in Wurtemburg.—The first electrical power in the province of Wurtemburg has just been put into operation in Königsbronn, where steam power has been replaced by electric power in the Royal Foundry. The installation has been carried out by the Esslingen Engineering Works. It contains a turbine which drives a dynamo at 600 revolutions per minute, and which gives 40 e.h.p. The current from this dynamo is transmitted by means of overhead conductors across the town to the Royal Foundry, where 25 turning lathes and polishing machines are actuated by electromotors.

Aberdeen.—On Tuesday, the Gas Sub-Committee of the Town Council of Aberdeen, instructed Mr. Smith, superintendent of the gas works, to report as to the sum which it would cost the Corporation to introduce electricity within the compulsory area defined in the Aberdeen Electric Lighting Order, 1890, and the amount for which an electric lighting company would work the undertaking. At a recent meeting of the Gas Committee, a letter was submitted from the manager of the Great North of Scotland Railway Company enquiring as to when the Town Council would be in a position to supply electricity, and the cost. The sub-committee are ascertaining the probable number of consumers of the light.

Newcastle.—At Wednesday's meeting of the Newcastle Town Council, Alderman Winter presented the report of the Town Improvement Committee as to the negotiations which have been going on between the committee and the Newcastle District Electric Lighting Company. The Council adopted the committee's recommendation to consent to the company's proposed provisional order on condition that the Corporation should have the option of purchase at the end of 31 years, instead of 42 years, from the commencement of the order, and that the maximum rate of dividend of 8 per cent. (cumulative) and all profits above such dividend, should be equally divided between the consumers and the shareholders. These terms have been agreed to by the company.

Blackfriars Bridge.—In the Chamber of Common Council on Jan. 29, the town clerk read a letter from the clerk of the Commissioners of Sewers, stating that the Commissioners had arranged with the Brush Electrical Engineering Company, subject to a contract being executed, to light the western district of the City; that the company were anxious that Blackfriars Bridge might be included in their area of supply, and that the Commissioners had referred them to the Corporation as the owners of the bridge, and desired to commend the application to the favourable consideration of the Court. Also a letter from the Brush Electrical Engineering Company making an application accordingly. It was decided to refer these two letters to the Bridge House Estates Committee.

North Metropolitan.—At the meeting of the North Metropolitan Company, allusion was again made to the difficulty with absurd regulations of the authorities at West Ham. There was not much encouragement to go on with electric traction until they were perfectly sure they would not be called upon to cease its use at 24 hours' notice. As will be remembered, the company are pressing forward a Bill in Parliament. The London County Council has given them powers for use of electricity for seven years without any absurd restrictions, and the object of the Bill was to obtain similar privileges from the West Ham authorities. If the latter gave them the same terms as the County Council they would not go on with the Bill, but if not they would continue their application to Parliament.

Hong Kong.—The Hong Kong Electric Light Company successfully commenced lighting the streets of Victoria (the chief town of the Island of Hong Kong) at the beginning of December last. The Hong Kong paper says "The light is beautifully bright and as steady as that of Old Sol himself. We congratulate Mr. Wickham (the manager) on bringing the undertaking to so successful an issue." The town is lighted up by about 90 arc lamps—60 on one circuit and 30 on another. These are Brockie-Pell double-carbon lamps, burning 32 hours, and is the first general application of these long-burning lamps to public lighting. There is great economy of carbons, besides the desirability of having so great a stand-by in case of fogs and darkness. The first pair of carbons are burnt right out before the second ones change over, and the lamps are trimmed usually only every other day.

Overhead Wires.—Mr. T. J. Haughton, of 27, Piccadilly, writing to the *Standard* on Tuesday, says: "At eleven o'clock on Sunday night I was walking up Regent-street from Waterloo-place. On reaching the entrance to York House (Junior Army and Navy Stores), I saw two ladies and a gentleman endeavouring to extricate themselves from a tangle of some kind, and before I had gone two paces further found I was likewise entangled. I stopped immediately, and found that it was a fine steel wire that stretched across the street, and had some difficulty in hauling it in, owing to the pressure of vehicular traffic. Roughly judging, I would say there was not less than 40 yards of it. I summoned the constable on duty at the junction of Jermyn-street, when we found the wire was fast to some upper storey of York House. The matter certainly wants explaining."

Arc Lighting in Australia.—The Government wharves at Sydney are lighted by Brockie-Pell arc lamps. The New South Wales Government are also about to light up the whole of the wharves at Bullock Island, near Sydney, with 50 of the same arc lamps. The town clerk of Port Augusta, the port of Adelaide (Mr. J. Holdsworth), writing recently, states that the two 3,000-c.p. Brockie-Pell arc lamps have been and are most successful. They are burnt outside the town hall, and the light is the steadiest he has yet seen in the colony, and is admired for its excellence by all visitors to the town. Flickering is conspicuous by its absence, and after three years' use the lamps seem to be equal to new. Such good reports as these must be flattering to the makers, and we hope will lead to a far greater extension of arc lighting in other parts of the British empire abroad.

Edinburgh Tramways.—At the meeting of the Edinburgh Tramway Company allusion was made to the mention of the Corporation taking over the lines in 1892. No official notice has been sent, and the directors, therefore, had put themselves into active communication with the various local authorities interested, with the object of having the company's powers prolonged on terms which might include an increase of capital for extension of the lines. The question of traction or motive power might also be involved. There were difficulties in the way of applying either the cable system or electricity to the company's lines. Regarding electricity, they did not know yet whether it was suitable for their steep gradients, and if so, at what cost it could be worked. In conclusion, the chairman moved the adoption of the report, with the recommendations therein, which were carried.

The Lighting of Sophia by Electricity.—A contemporary publishes the following particulars in reference to this contract: The plant was to be installed at the Government printing office, and current was to be supplied to the Palace about half a mile away, and to the Sobranje, 286 yards distant. The total light required was estimated at 12,500 candles by arcs, and 25,000 candles by incandescents. A storage battery was to be employed as a reserve. The following is the list of tenders for lighting the town by electricity:

Egger and Co. (accepted)	£9,328
Ganz and Co.	9,535
Schuckert	9,768
Siemens and Halske	11,158
Sautter-Harle	11,600
Société Gramme	13,440
Kremenezky	13,500
Compagnie Continentale Edison	15,120
Compagnie Continentale Edison	15,881
Crompton and Co.	11,120
Crompton and Co.	15,290
Allgemeine Elektricitäts Gesellschaft	15,940
Southgate Engineering Company	16,896
Société d'Appareillage Electrique (Paris)	18,000

Liverpool Overhead Railway.—This railway will be a double line for passengers only. It is to extend from Fort-road, Seaforth, at the north end of the dock estate, to the Harrington Dock at the south—nearly seven miles. At first steam was proposed as the means of propulsion for the trains, but the progress of electric science now renders it probable that steam will be abandoned and electricity substituted. On this head, however, a decision has not yet been made. A traffic of over 5,000,000 persons is confidently expected for the first year. The chief engineers are Sir Douglas Fox and Mr. G. H. Greathead; the resident engineer is Mr. Francis Fox, who has as assistants Mr. Ernest Wilcox and Mr. S. B. Cattrell. Mr. J. W. Willans, of Manchester, the contractor, has had previous experience in railway construction, having been connected with the subway in London, recently opened by the Prince of Wales. There being no engineering difficulties in the way, progress with the new line is fairly rapid. It is complete from Fort-road to the Alexandra Dock. The foundations are laid for another two miles, and upon these the columns have been erected for nearly a mile.

Electric Preparation of Hydrosulphite of Soda. Hydrosulphite of soda is a salt not much used in commerce; it is almost exclusively used in dyeing, either to lighten indigo tanks or to bleach silk or wool. It is almost always prepared by the Schützenberger process, which consists in making zinc react upon a solution of bisulphite of soda. These manipulations are long, and the cost is high. An electric process has been described by M. Villon, both more rapid and cheaper than the present one. The bisulphite of soda is reduced by the electrolytic hydrogen; 88 kilogrammes of bisulphite of soda, require to be completely transformed, three kilogrammes of hydrogen instead of two, the theoretic figure. The operation is carried out in a pine trough with porous earthenware divisions: one compartment contains the negative carbon electrodes in 300 litres of bisulphite of soda at 35deg. Beaumé; the positive electrodes dip into a solution of sulphuric acid diluted with 10 times its volume of water. The trough is hermetically sealed, and the current is passed until four kilogrammes of hydrogen is formed. This operation takes 350 horse-power hours. The hydrosulphite is then ready for use. The net cost of these 300 litres is 6f.

Tramway Legislation. — Now that electrical engineers are likely to go in for tramway work it might be of use for them to give some attention to the state of the Tramway Acts, which was the subject of the discussion at the British Tramway Institute. It was obvious, maintained the president (Mr. W. J. Carruthers Wain, C.E.), that within the limited time allowed by the Act of Parliament, it was impossible for any company, however favourable the circumstances, and however well managed, to build up such a reserve as should take the place of the ordinary capital, and be able to repay it at the end of 21 years. There was no tramway company in this kingdom or in any other which could do it. After expending a large sum of money in the construction of an undertaking for the public benefit, and after having received only a very limited profit, perhaps none at all, the Legislature never contemplated that the whole of the money invested should be absolutely confiscated. He thought they would agree with him that it was absolutely necessary that one of the first points to which the committee he suggested should direct their attention with regard to legislation for the future of tramways, should be a clear and distinct definition of the price at which a tramway should be sold if a local authority wished to buy it. The resolution was moved and adopted: "That it be referred to a committee, consisting of the president and vice-presidents, to consider what action should be taken with a view to early legislation to amend the Tramways Act, 1870."

London County Council.—At the meeting of this body on Tuesday, the report of the Parliamentary Committee was brought up. It contained the following recommendations as regards the Central London Railway Bill: "(1) That a petition be presented against the Bill, with a view to the protection of the sewers and other interests of the Council, and for the insertion of clauses prohibiting buildings in advance of the general line, or such other provisions as will prevent traffic accumulating on the pavements at stations, and subjecting buildings over stations to the Building Act, and requiring the frontage line of buildings at the stations to be set back." This was adopted. Also (2) "That the Council's petition should contain a provision asking that clauses for the ultimate purchase of the undertaking by the local authority, similar to those at present contained in the Tramway or other Acts, be inserted in the Bill." The following amendment by Mr. Saunders was adopted—viz.: "That it be an instruction to the Parliamentary Committee that, in the event of the owners of land adjoining the line of the proposed railway seeking to obtain clauses in the Bill which would authorise them to obtain payment in respect of ground under the surface, the Council shall strenuously oppose the insertion of such clauses, which, if admitted, would establish a precedent seriously prejudicial to the interests of the inhabitants of London." With regard to the City and South London Railway (Islington Extension) Bill, the committee made similar recommendations; and also recommended that a petition be presented against the preamble of the South Kensington and Paddington Subway Bill.

Electric Light at Durham Cathedral.—During the past week a series of experiments have been made in connection with the lighting of Durham Cathedral by electricity with thoroughly satisfactory results. Messrs. E. Scott and Mountain, of Newcastle, erected a trial installation for the Dean and Chapter, and the choir was illuminated with 48 16-c.p. incandescent lamps, 12 being affixed to each of the choir candelabra, and 12 to each of the gas standards within the altar rails. The illumination was far superior to that afforded by the present gas lighting arrangements. One of Messrs. Scott and Mountain's Tyne compound dynamos, driven by a small vertical steam engine, was placed in the stone yard, and the current conveyed by means of cables to the fittings in the choir. It is proposed to extend the electric light throughout the entire cathedral, the present experiments being for the purpose of determining the actual quantity of light required and the best arrangement of the lamps. If the results are deemed satisfactory, the Dean and Chapter will proceed with the scheme of lighting the cathedral by electricity. In the event of the scheme which has been proposed by the electricians being adopted, the River Wear will be utilised to work the turbines, which will provide the necessary power not only for lighting the cathedral, but also the residences in the college. If this scheme is adopted, it is proposed to put in accumulators of ample capacity to supply the current to the cathedral and to the houses, to provide an ample safeguard against any possible failure of the light. In addition to this, the scheme provides a dynamo of sufficient power to run the whole of the lights, so that under ordinary circumstances the accumulators would not be required. But the method proposed is to charge the accumulators during the day and utilise the stored current for the cathedral services and the canons' residences in the evening. If the scheme is adopted, the nave will be lighted by five candelabra similar to those in the choir, each of which will have 20 lights. Each transept will be similarly lighted.

The Westinghouse Company. — Rumours of a startling character have been bandied about with reference to the great Westinghouse Electric Company, and it has been necessary to make known that a financial crisis was to be feared. The long years of costly litigation, of growth of an enormous business beyond safe limits of cash capitalisation, and the acquisition of important but costly rights, have run the company, in a word, short of current cash, and Mr. Westinghouse has shown a disposition to throw in his private fortune by securing a loan of half a million to tide over the difficulty. The bankers into whose hands the matter came felt the business to be too un-familiar to them to accept this arrangement, and it has been decided to issue preferred stock to raise funds to meet the exigencies of the business. The creditors show a disposition to help the extraction from the present difficulties, and the negotiations for the stock are progressing to a satisfactory conclusion, and there is good reason to believe that confidence in this corporation, which has certainly done so much to spread electrical work and has carried out enormous and profitable business, will be restored. In an authoritative statement, given by request of George Westinghouse from himself to the *Electrical World*, it is pointed out that there are eight distinct corporations unconnected with each other except through the ownership of Mr. Westinghouse of a controlling interest in each. The Westinghouse Air Brake Company, the Union Switch Company, the Westinghouse Machine Company, the Philadelphia National Gas Company, the Standard Underground Cable Company, the Allegheny County Light Company, the Fuel, Gas, and Manufacturing Company, and the Westinghouse Electric and Manufacturing Company. Of all these it is the last only that is in financial trouble. All the capital it requires can be secured by the placing of from thirty to forty thousand shares of the par value of 50dols. each of its preferred stock, either for cash or in settlement of outstanding obligations. Mr. Westinghouse is now devoting himself to the placing of this stock, and is very hopeful of success. The total sales of all of the companies named amounted in 1890 to over 15,000,000dols.

Mr. W. J. Hammer's Debut.—One of our pleasantest recollections from the time of the Paris Exhibition, and indeed of other times, is of Mr. W. J. Hammer, Mr. Edison's manager, engineer, general superintendent, and designer of the Edison exhibits in Europe and elsewhere. Mr. Hammer is one of those men who make everything go; genial, full of knowledge and varied experience, and full of resource, having held important positions in the practical as in the commercial part of those huge Edison electrical companies whose rise is such a feature of American work. Often called upon to go here and there over the world, on their behalf, at a few hours' notice, and to engineer, arrange, and supervise large and varied installations, Mr. Hammer has, perhaps, made his name more known by his original and striking arrangements for the great exhibitions than almost any other modern man. From an ingenious and equally striking and original prospectus that we have just received from Mr. Hammer, we notice that he has set up an office and career of his own, as consulting and supervising engineer; thinking, and no doubt rightly, that so great is the advance of modern electric science that capable and independent advisers to those who wish to introduce the latest applications of electricity will have as much scope as have architects and consulting engineers. Mr. Hammer, to illustrate his capabilities in this direction, issues specimens and testimonials in as tasty a way as he can devise. Photographic reproductions of the Paris exhibits, the novel electric displays at Cincinnati, the Crystal Palace, and the Franklin Institute are given, together with the famous Ponce de Leon Hotel at St. Augustine, Florida, which was placed under his control, and for which he designed novel scenic effects in the grounds. Mr. Hammer also characteristically reproduces original letters of laudation and acknowledgment from what he terms the "crowned heads" of electrical science—Edison, Elihu Thomson, Frank Sprague, and the presidents of the Edison and Westinghouse Companies, with a specimen digest from an elaborate report prepared by him as chief inspector of central stations to the Edison Company, embracing tests of engines, boilers, dynamos, and apparatus in minute detail. To finish, there is given a most amusing and interesting account of a New Year's entertainment given at his own house, where every conceivable effect, dodge, scene, useful, beautiful, and startling application of electric light and force were concentrated, to the bewilderment and wonder of the guests. We wish Mr. Hammer all success in his new sphere, and doubt not that he will achieve it.

Birmingham.—Before the Birmingham City Council on Tuesday the report of the Public Works Committee was submitted, dealing, amongst other things, with the application to the Board of Trade of the Birmingham Electric Supply Company. In moving the adoption of a recommendation that the Council consent to the application, subject to the insertion of clauses giving effect to certain alterations proposed by the committee, Mr. Parker said that the order was for the purpose of obtaining certain small extensions of the area included in the order of 1889. The object of including these supplementary areas was that they would give more convenient access to the properties which the company were proposing to light, and with less disturbance of important streets for the laying of mains, etc. The committee were anxious to guard against the company obtaining more than was reasonable and right, and had obtained their consent to give up two areas which the committee did not think it was necessary for them to acquire. With these omissions the order asked for would give a more compact area wherein to try their experiment. Alderman Pollack having given statistics as to the progress of electric light in London and elsewhere, Alderman Avery asked whether the adoption of this resolution would not affect the possibility or the probability of the Council becoming the electric lighting authority. Mr. Lancaster agreed with Alderman Pollack that the Council should take up electric lighting, but he did not think that electricity as an illuminant would always be dearer than gas. He thought that the resolution meant giving the company the finest plum in the matter of electric lighting area. He believed that by-and-by the Council would take over the works and provide electric lighting for the whole town. Mr. Barclay thought the Council ought never to have allowed the matter to pass out of its own hands. Mr. Fallows thought that when the concession was granted to Messrs. Chamberlain and Hookham the Council took power to acquire the undertaking in a certain time. Mr. Beale reminded Mr. Barclay that if the Council had not given their consent to the provisional order, the Board of Trade might have taken the matter out of their hands. What was proposed now was not to give the company any additional area, but to make the area already granted more useful, not only to the company, but to the city, Mr. Parker, replying, said that there was a good reason why each one of these additional areas should be given on its merits. The committee quite agreed to what had been said as to the desirability of doing nothing which would prevent the Council from becoming the electric lighting authority. They had to bear in mind that they had, both this session and last, given the Board of Trade to understand that they would not prevent anybody having powers in Birmingham, but that they desired to see the experiment tried, and proposed the resolution to give all reasonable facilities for the purpose. The additions to the area were to ensure as little disturbance to New-street as possible, and another reason was that the present company's station was in Dale End, whereas Messrs. Chamberlain and Hookham, the original *concessionaires*, intended supplying the area from Bartholomew-street; and another was to facilitate the lighting of the Victoria Courts. The motion was agreed to.

UNDERGROUND MAINS.—III.

THE CALLENDER-WEBBER SYSTEM.

(Continued from page 123.)

The actual process of laying the Callender-Webber mains is as follows:

The course of the main is first laid out, and the trench dug to the required depth. The trench is made in as straight a line as possible, and is somewhat carefully levelled, a good foundation being secured by ramming down the soil. Occasionally rough concrete is employed in the trench to bed the conduit, but this is necessary only in exceptional circumstances. As long lengths as are permitted by the authorities are opened at a time, arrangements being made to avoid interference to the traffic by bridging the trench where necessary. At crossings, however, the work is done in short sections to avoid blocking the traffic. The surplus earth is everywhere carted away regularly.

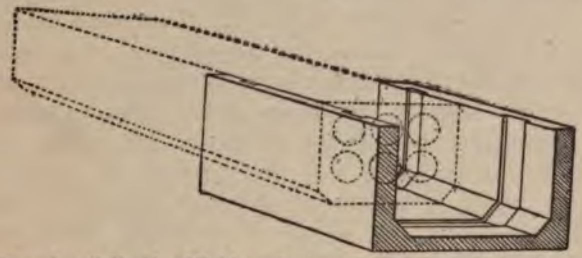

FIG. 5.—Callender-Webber Casing Joint with Saddle Piece.

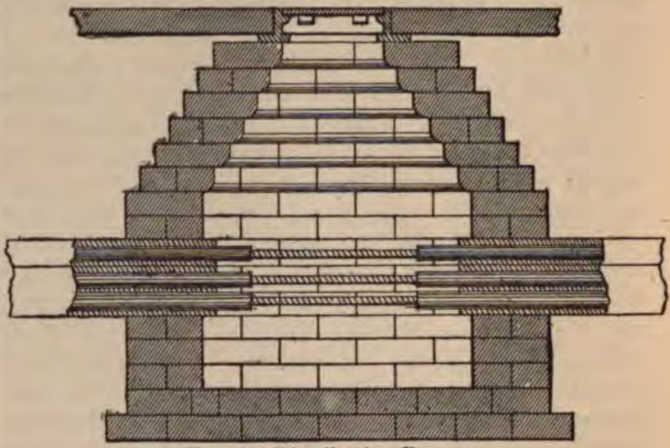

FIG. 6.—Distributing Box.

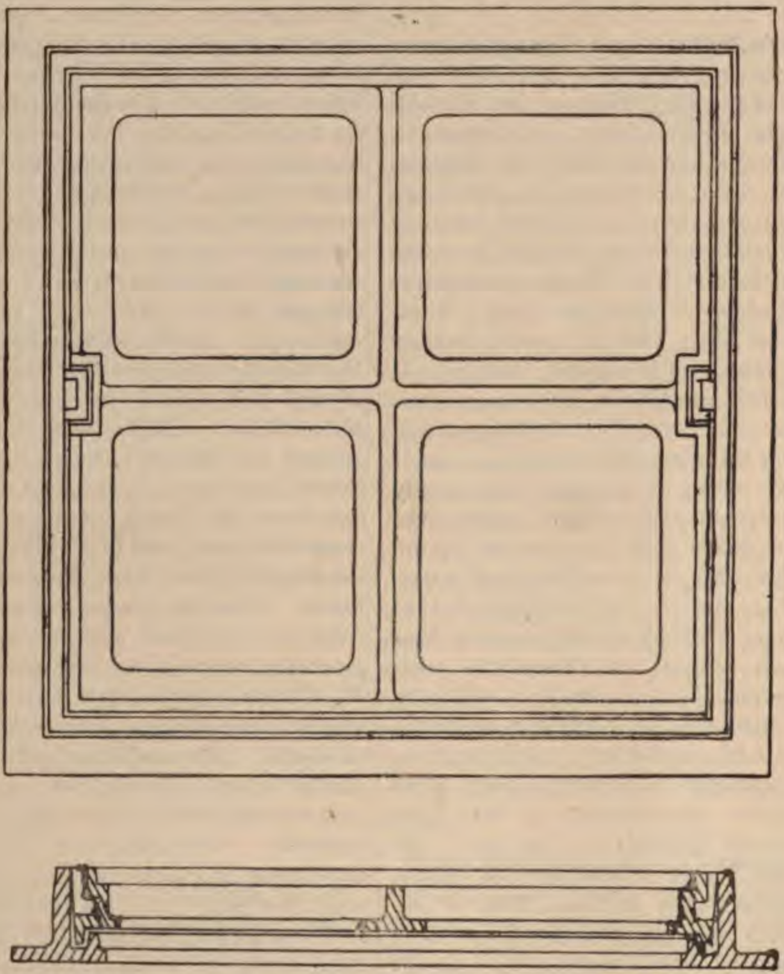

FIG. 7.—Detail of Coverplate.

The bitumen casing is next laid upon the bottom of the trench and jointed together. This jointing is carried out length by length to form one solid and continuous casing. Each fresh 6ft. length is placed on the ground, with 2in. to 3in. interval between it and the one already laid. In the meantime some bitumen concrete is being heated in the large iron cauldrons. Mandrels are pushed through each of the holes in the casing, joining the two sets of holes together. Then the bitumen concrete is run in, stamped into position, and shaped into the same shape as the original casing. The joint is thus made absolutely waterproof, and the mandrels ensure the holes being smooth and continuous; the result is practically one solid bitumen casing, and except for the newness of the material, a person passing along can hardly tell where the joint has been made. The mandrels are then pulled out, the earth thrown in again, rammed down, and the road repaved.

In certain circumstances where the mandrels cannot be used, a different method is adopted. The ends of the casing are butted together (see Fig. 5), and saddle pieces of material similar to the case itself are placed at the joint, which is made tight by a little bitumen seared with a hot iron.

The next detail is the construction of the drawing-in boxes.

These are constructed in a simple manner by the building of a pit in brickwork at the places required, in the manner shown in Fig. 6. In the larger sizes these are made 3ft. by 3ft., and about 4ft. deep. The bottom is not concreted, but left in ordinary brickwork, so that any moisture that may get in may easily drain away. The walls of the pit are built up, and the bitumen casings are so arranged that they project about 6in. into the pit. Above them the brickwork, overlaid and tapered up, as shown, forms a manhole in the surface of the street, having a cast-iron box and removable lid.

The cover plates are generally made 18 by 12, 20 by 15, 24 by 15, or 24 by 24 inches, according to the size of the pit. The plate on the footpath is filled in with cement to resemble the paving in which it is placed. In some cases, where access is not often required, it is often found desirable to seal in these boxes. For this purpose the boxes are cast in a special form (see Fig. 7), so that a second lid can be placed on the inner rim there seen under the pavement lid, and the box then made absolutely watertight by sealing in the false lid with red lead or asphalte.

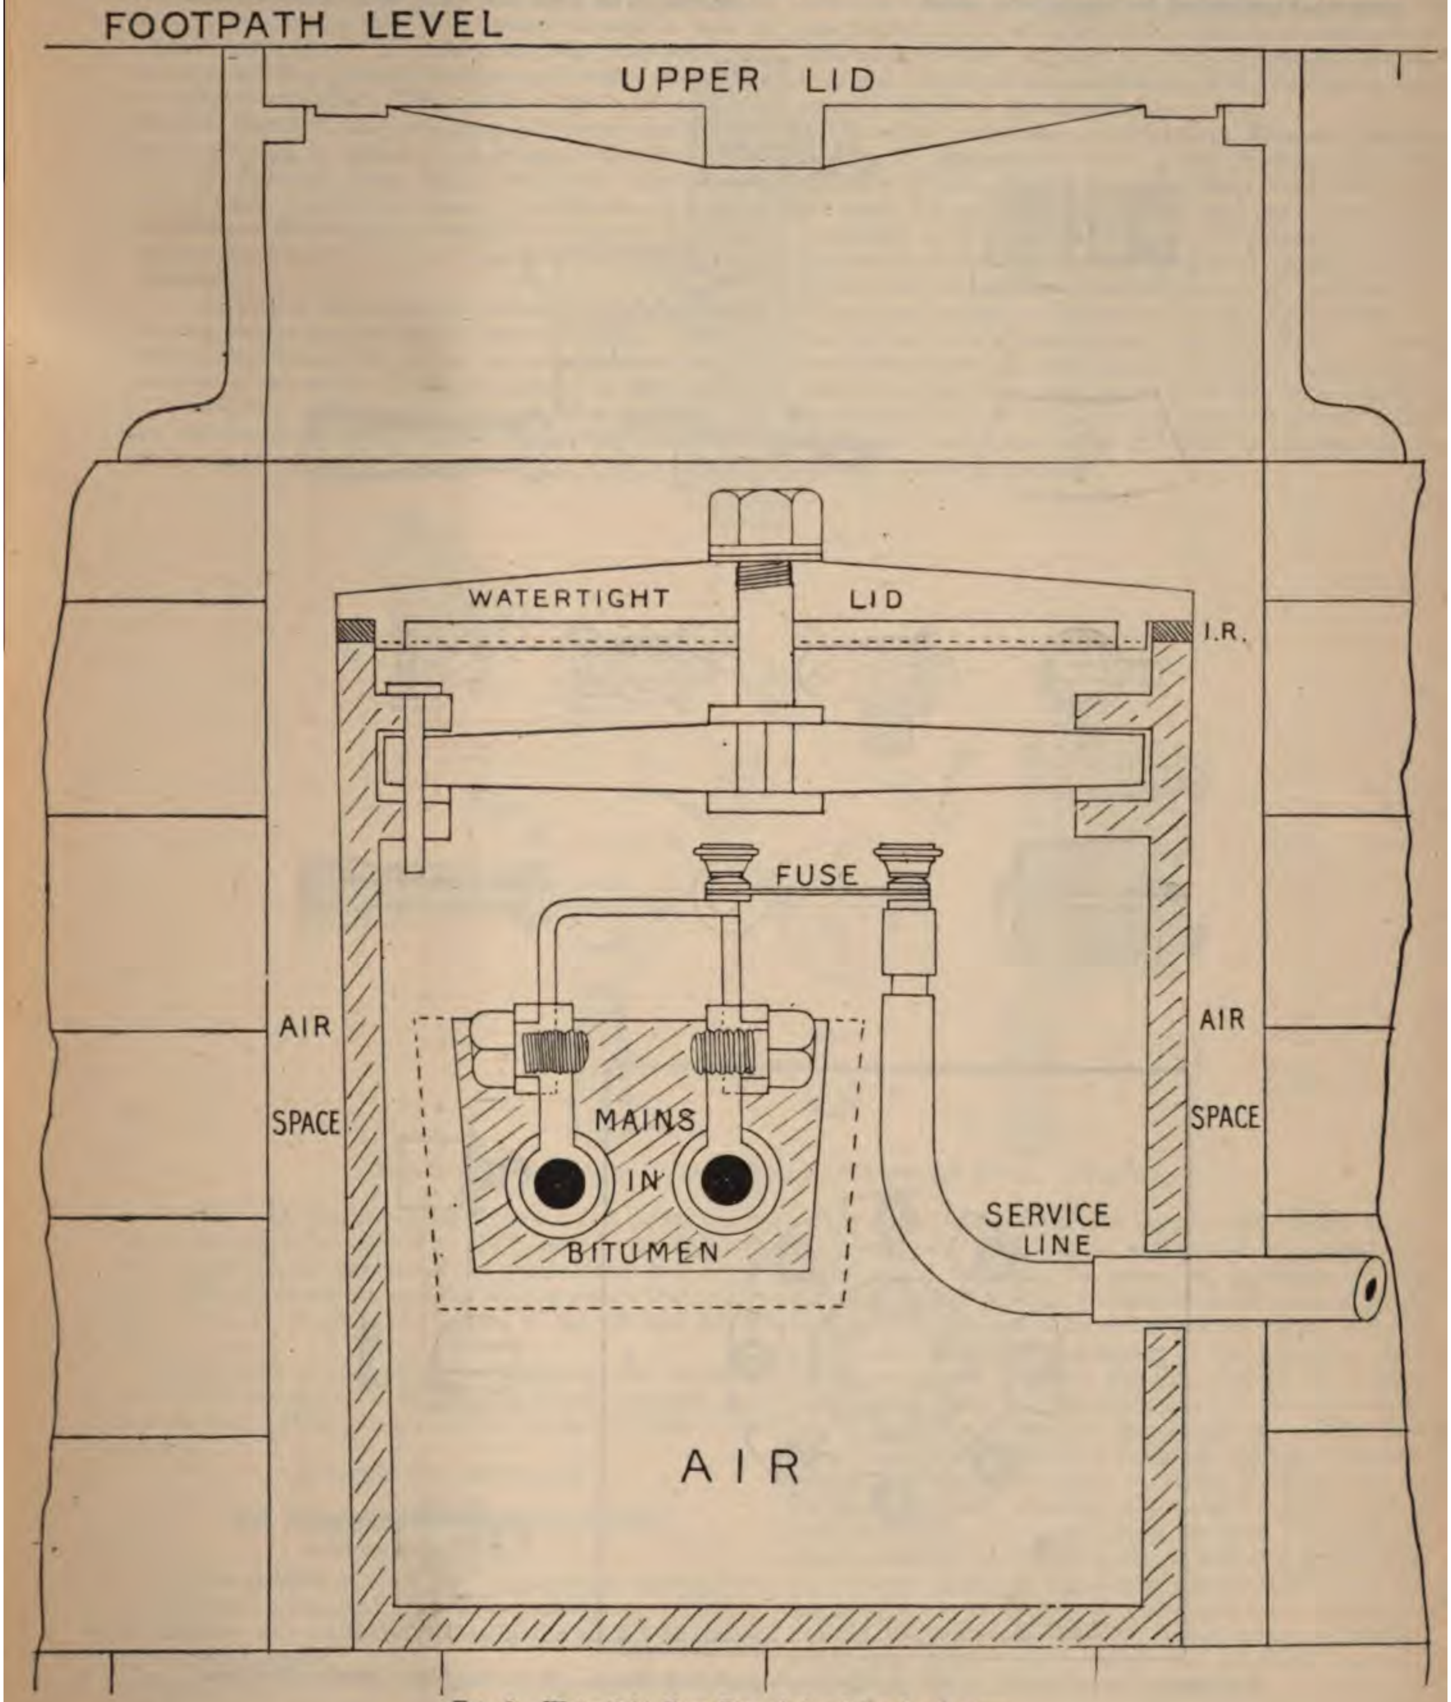

Fig. 8.—Watertight Fuse Box of the Callender System.

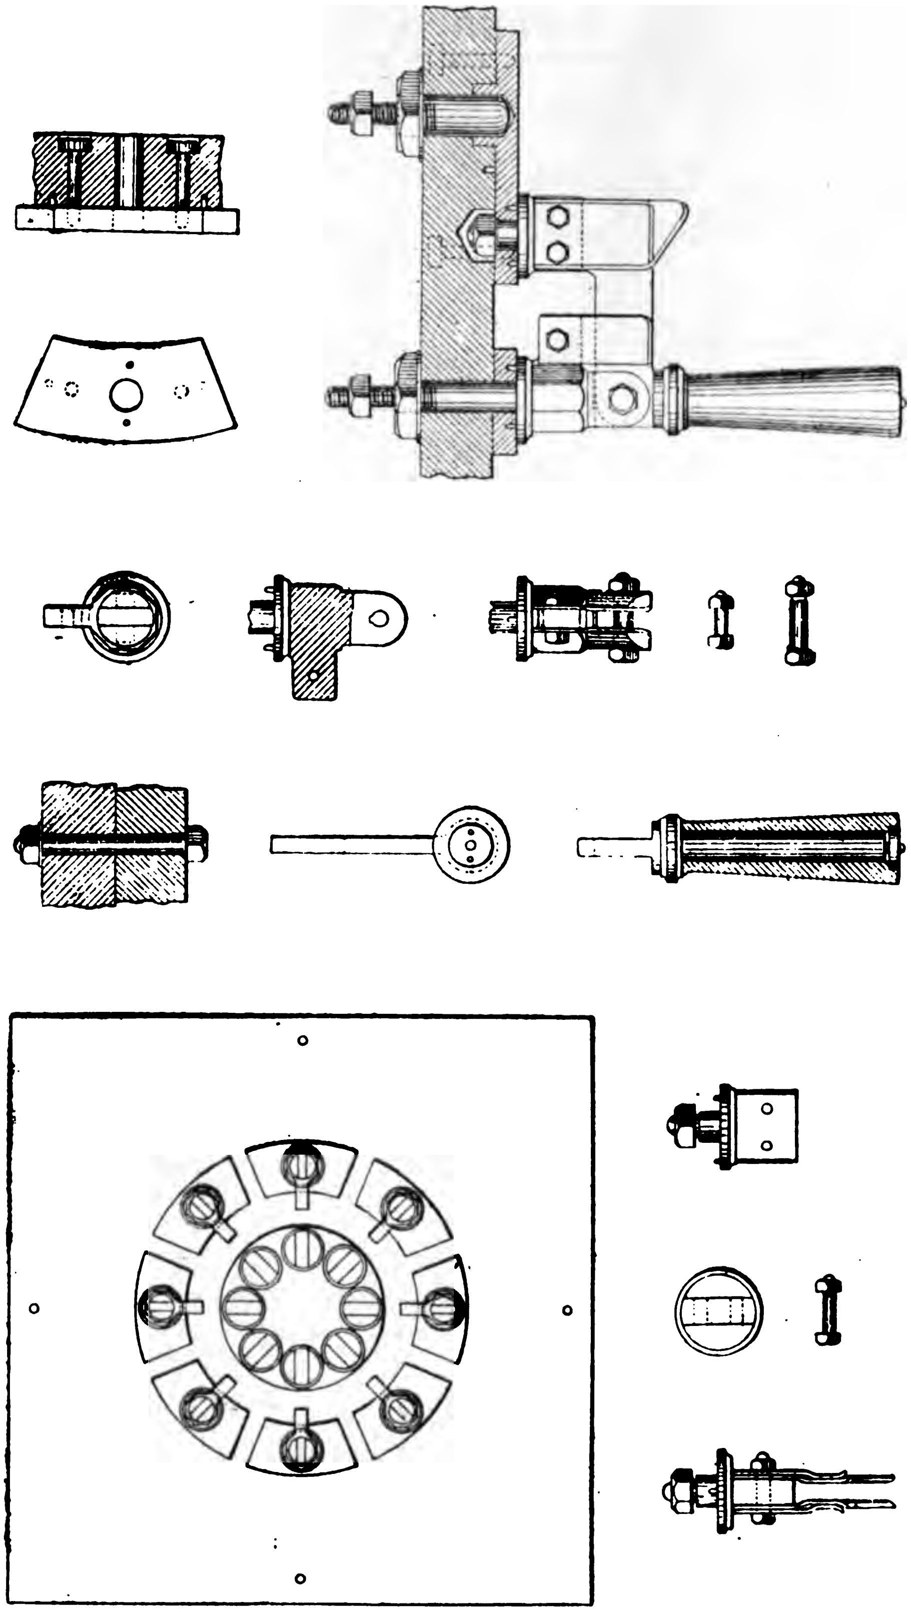
Three different kinds of boxes are in use :

1. Feeder boxes, for the connecting of feeders to distributing mains.

2. Service boxes, for the connection of mains to cus-

tomers' mains at points where large supplies of current are to be taken off.

3. Supply boxes, for the supply of householders, put in, if required, when service boxes are too far away. These latter are usually constructed of cement or brick built round the conduit after it is laid, so that the conduit is cut at the point most convenient for tapping the cables.



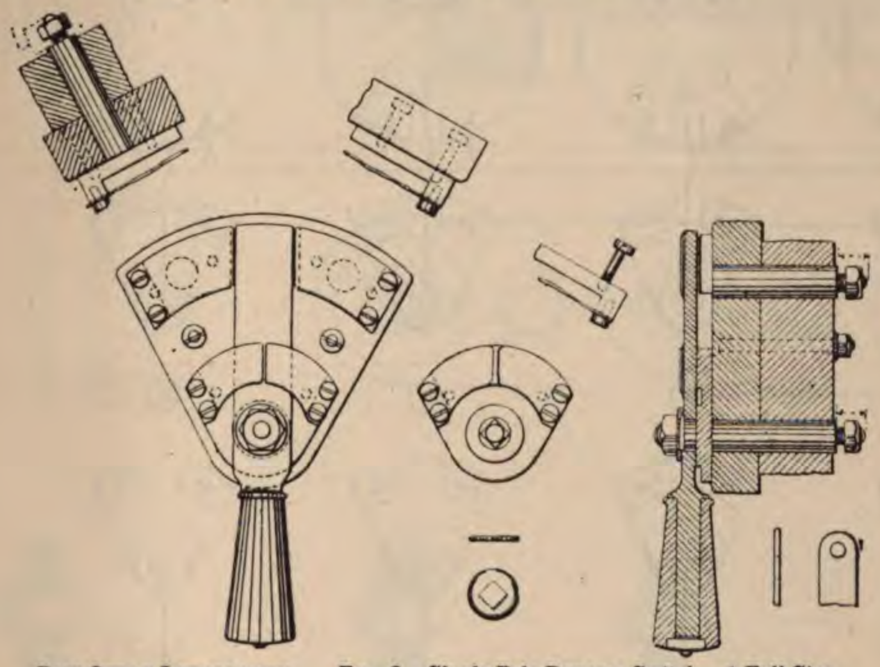
Post Office Installation. Fig. 1.—Engine Room Switch Board. Plan ⅛ Full Size. Details ¼ Full Size.

When the conduit is all laid and the various boxes properly built, the drawing-in of the cable itself follows next. In the smaller sizes of casing a cord is passed in as the conduit is laid. The mandrels are specially made with a hook at the end, to which the cord is fastened as each length of casing is laid and the mandrel withdrawn, the cord is therefore drawn through. With the larger sizes of holes such a precaution is not necessary, and when the conduit is laid a jointed rod—something like a sweep's rod—can easily be pushed through from box to box. This is attached to a cord, which in its turn is drawn through and pulls in a rope. The rope is attached to a cable, which is pulled in either by a number of men hauling or by the aid of a winch. The ways are quite smooth inside, and 500 or 600 yards (⅓ mile) in one length of cable can be drawn in without any great difficulty. Lengths such as these would only be used for feeders or for supply mains in the country, and for town supply the lengths would be of from 50 to 100 yards, or often less where the demand was heavy and service boxes numerous.

The cables that are used are Callender cables of high insulation with dielectric of vulcanised bitumen, and are made as follows: The conductor is of stranded copper cable of not less than 98 per cent. conductivity. This is first covered by a solid sheath of bitite (bitumen vulcanised under the Callender process) put on under heavy pressure at one operation. This core is then served with tape and insulating compound, and again served with either jute yarn or additional tapes, finally braided with hemp yarn and passed through a bath of asphalte compound. The cables are thus made extremely durable, resisting perfectly themselves all action of moisture or coal and sewer gas. When laid in the solid casing of bitumen, therefore, they are practically indestructible. The bitumen is also, it appears, a thorough protection against rats, for although these mains have been laid now for several years, the rats have never been found to bite either the cables or the casings, although it is known they have made in some cases the spare holes in the casing their mode of travel.

In connecting the mains to branch or service supply circuits, the course is often adopted of building what are termed fuse-boxes, Fig. 8, in the ground, in which the junction of the service line is safeguarded by the insertion of a solid fuse. The outer pit is made of a depth to suit the position of the casing with its wires. The inner box is made watertight, and is placed inside the pit with air space around it. The bitumen casing projects a few inches inside the inner box, to which it is carefully sealed with bitumen. The upper lid or manhole of the whole street box is set flush with the pavement, and any little moisture that might get in simply drops to the bottom of the pit and filters away.

The method of connecting the feeders to the mains is simple and ingenious. It is the same in both systems, and will be described in our next article on the Callender solid system.



POST OFFICE INSTALLATION. FIG. 2.—Single Pole Dynamo Switch. ¼ Full Size.

THE POST OFFICE INSTALLATION.

We give on these and following pages various illustrations of apparatus connected with this installation. Further illustrations and a full description of the plant will appear in a future number.

Fig. 1 shows the details of the engine-room switchboard ⅛ full size, details ¼ full size.

Fig. 2 shows a single pole dynamo switch ¼ full size.

Fig. 3 is a plan of the distributing switchboard—ground floor.

Fig. 4 shows details of same.

The plan is one-eighth full size, and the details are half full size.

ELECTRIC MINING MACHINERY.*

BY LLEWELYN B. AND CLAUDE W. ATKINSON, A.MM.I.C.E

During the last four years the authors had been constantly connected with the application of electricity to mining, and had spent a considerable amount of time underground, both in experimental work and in teaching those who would have charge of the electrical machinery. It was pointed out in what way the conditions of mining work differed from those existing in other industries, and how they had been dealt with, and some of the machinery now actually employed was described.

The use of compressed air was then discussed, and the results of experiments were given, showing that the efficiency of this method of transmitting power was 45·8 per cent. for an air pressure of 19lb. per square inch, decreasing to 25·8 per cent. for an air pressure of 40lb. From more recent experiments by Prof. Kennedy, F.R.S., M.Inst.C.E., it was found that in practice an efficiency of 31 per cent. might be realised, or 45 per cent. if the air was heated before being passed into the motor. In the case of the electrical transmission of energy, except when distributed into very small units, there was little difficulty in obtaining 50 per cent. of the power expended in the engine, and there were cases in which an efficiency of 75 per cent. had been realised.

One of the most important points with regard to the employment of electricity in coal mines was whether a motor would be likely to cause an explosion. It was necessary in the case of a machine which perhaps might have to work for several hours without attention to guard against the possible accumulation of an explosive atmosphere around the brushes. For this purpose the authors had enclosed either the whole armature or the commutator only in a practically air-tight casing, and the method had been successfully applied to a motor of 40 h.p. The temperature had been kept down to 70deg. F. above that of the atmosphere by allowing a sufficiently large cooling surface—namely, 2·3 square inches per watt. To meet the objection that if the fire-damp should leak into these covers the resulting explosion might be as disastrous as if they did not exist, it was pointed out that whenever the proportion of marsh-gas to air exceeded 3 or 4 per cent., combustion would take place quietly, and the resulting carbonic acid would tend to prevent explosion in the case of farther leakage. Moreover, the authors proposed, in special cases, to introduce a constant supply of carbon dioxide from a steel cylinder into the interior of the casing, thus preventing the ingress of an explosive mixture. Similar methods were adopted for enclosing the switches, and sparking was prevented by providing a resistance coil of small self-induction, which was always connected to the ends of the magnetising coil so as to form a path through which the current in the latter might continue even when the main circuit was broken. The switch itself also had a resistance coil connected to the several points with which it made contact, so that by slowly opening the circuit sparking was practically done away with.

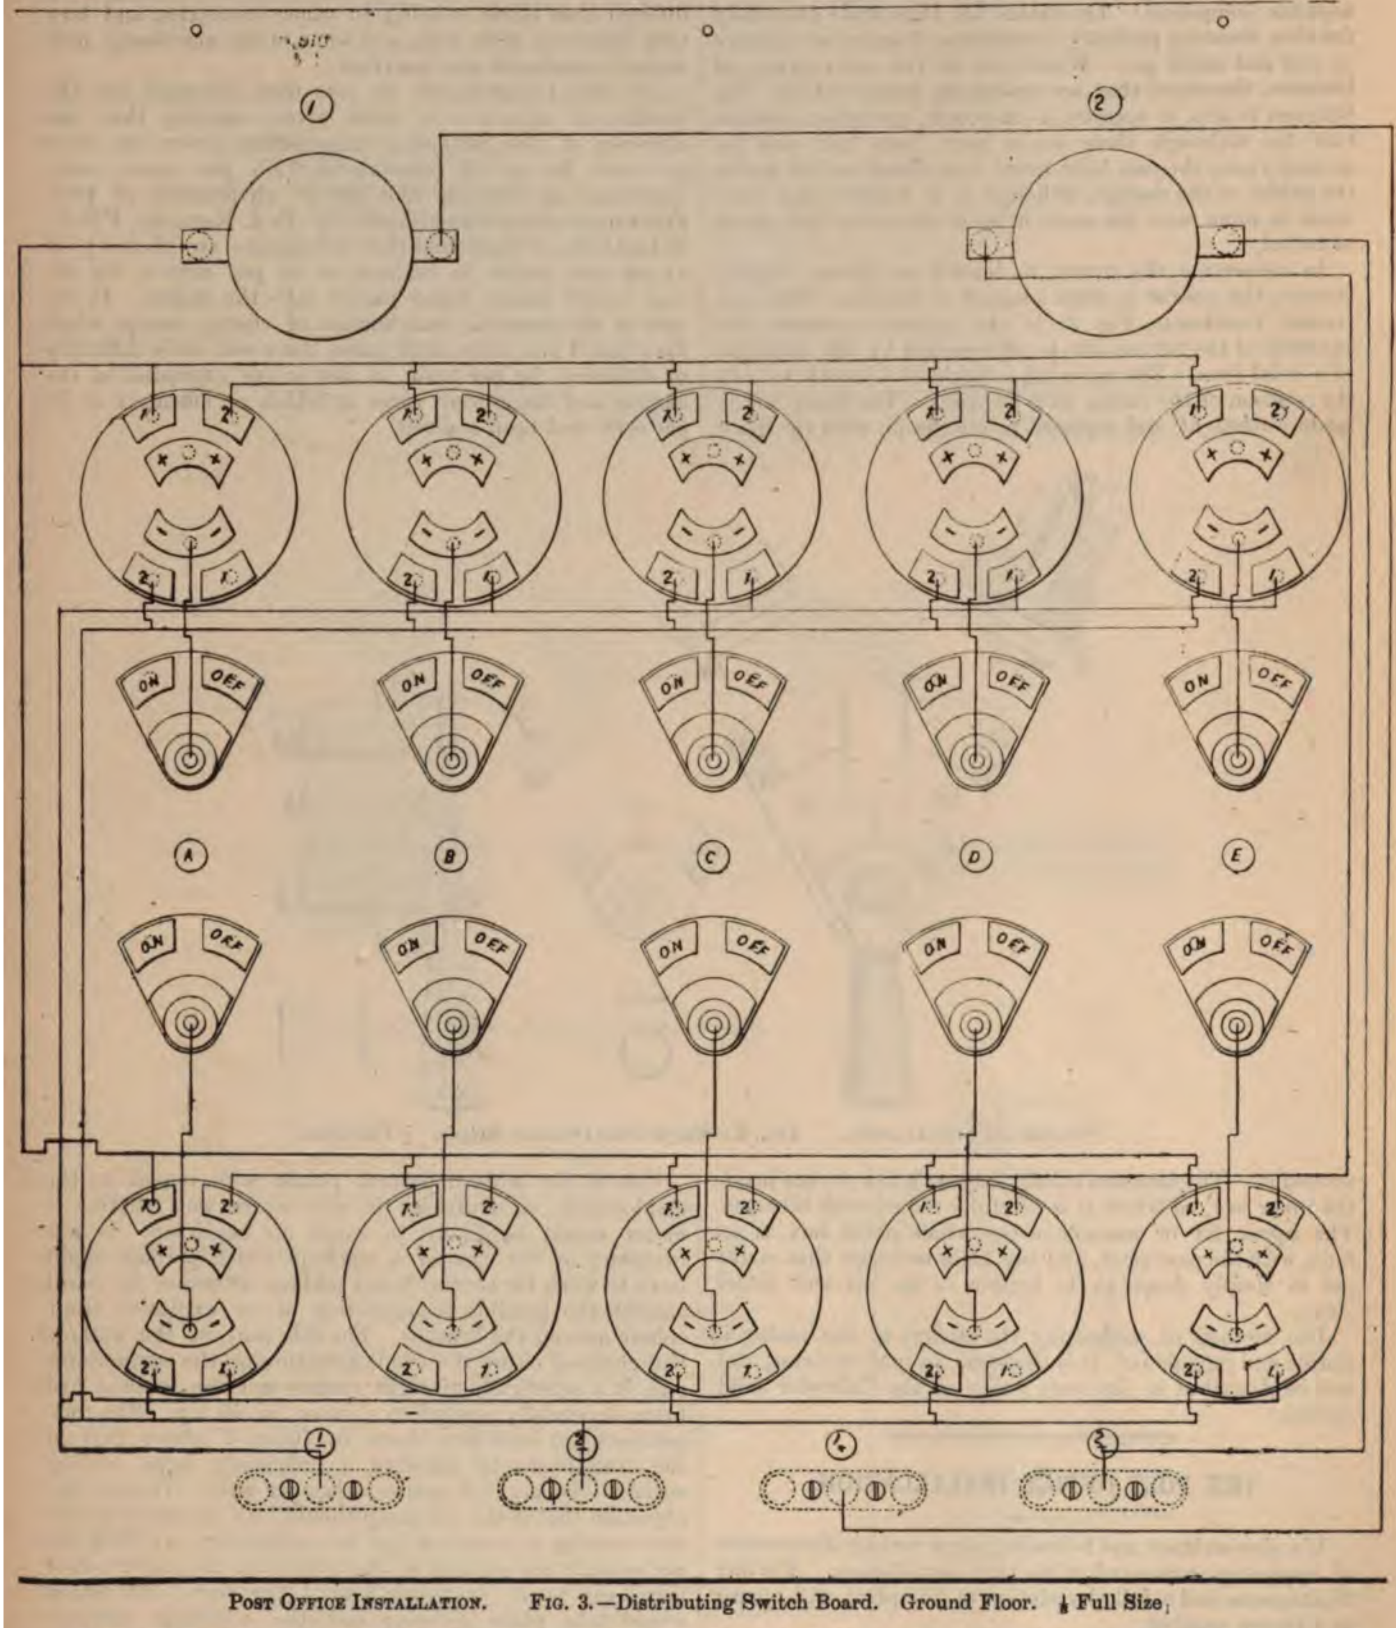
* Abstract from paper read before the Institution of Civil Engineers.



Post Office Installation. Fig. 3.—Distributing Switch Board. Ground Floor. ¼ Full Size.

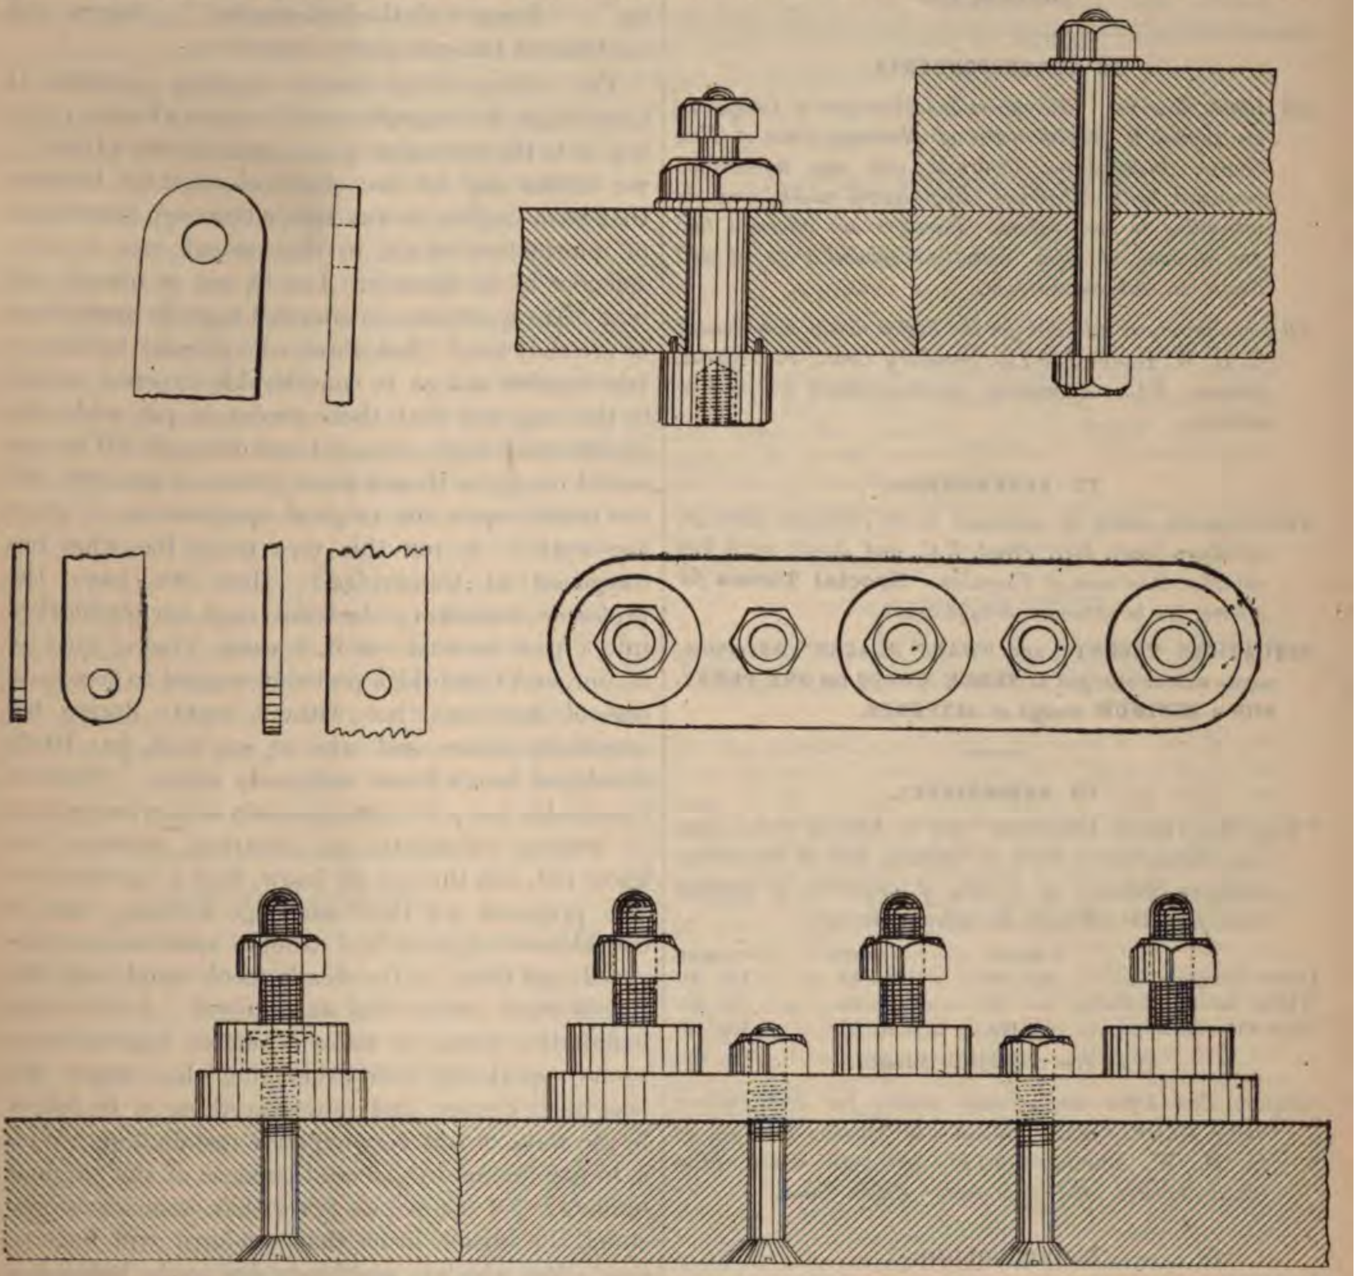
The application of electricity to pumping in mines was then described and illustrated. The use of belts for driving was not recommended on account of the want of space and the difficulty of keeping them in good condition in dirty and wet situations.

The employment of electric power for actuating coal-cutting machinery was suggested in 1873 by Mr. Henry Wilde, and first practically applied by Mr. F. Mori, in 1887, whose machine was illustrated. It had a cutter of the bar type, revolving upon its axis, and was driven by a dynamo having a normal output of 10 h.p., situated at a distance of about a mile. It was built by Messrs. W. T. Goolden and Co. Their next machine was one in which the armature shaft itself was made to carry the cutter-bar. Later developments of these electrical coal-cutters were given. The proper form and dimensions of the cutters were then discussed at some length, the authors preferring the bar type to that in which the tools were fixed into the periphery of a disc, not only as being less liable to be held fast by a fall of coal, but as cutting to a much greater depth. The cutter-bar ran at the rate of 500 revolutions per minute, and on an average, including stoppages, from 20 to 30 square yards per hour might be cut in fairly hard coal. At Lord St. Oswald's colliery at Nostell, 55 yards were bared to an average depth of 3ft. 8in. in 75 minutes. The relative cost of cutting coal in this way and by hand showed a difference in favour of the machine of 1s. 6d. per ton.

An electric boring machine was described, and also an arrangement for driving an Ingersoll percussive rock-drill by electricity, as well as a special form of dynamo adapted for use in transmitting power for electric mining work, with a high voltage.

The authors arrived at the following conclusions :

(A.) That electric power was destined to become an important factor in mining mechanics, on account of—1. The facility with which it could be used with machines which required to be moved from time to time. 2. The great economy in first cost and reduced cost of working owing to its efficiency being higher than that of compressed air or any other medium of power transmission. 3. The smaller cost of maintaining the cables, as compared with piping, on shifting floors in roadways, etc.



Post Office Installation. Fig. 4.—Distributing Switch Board. Ground Floor. Details ½ Full Size.

(B.) That the methods described were sufficient to obviate all objections to the use of electric motors in coal mining, whether by excluding inflammable gases, or by constructions which would allow of their safe combustion.

(C.) That the experiments, trials, and practical work, extending over four years, showed that—1. Electrical pumps might be used with advantage and economy for mine draining. 2. Electrical coal-cutters could replace hand labour, with saving in cost, and increased production of coal. 3. Electrical drilling machines were available in place of machinery worked by hand or compressed air.

A NEW SCALE.

Mr. W. F. Stanley has introduced an improvement in draughtsmen's scales. We all know how quickly ordinary scales wear out at the points where mostly used. In order to avoid this, Mr. Stanley has introduced a new scale of the first divisions of the scale, by a duplicate in brass of this part of the scale. If this duplicate scale is always used for setting off small dimensions with the divider, it will enable such to be done conveniently, the working edge being thereby preserved for larger dimensions. Another advantage connected with the small brass scale is, that it permits the bows to be set on it without injury, even the ink bow when charged with ink.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VI. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

We may occasionally follow the lead of our American Contemporaries, especially when they point out a serviceable way. They are not backward in asking their friends to do all they can for the welfare of the paper. We ask our friends to remember us. No Paper that we know ever refuses Subscribers or Advertisers. Nor do we; in fact, we invite them, believing that they will get full value for their money.

Specimen copies of the paper will be sent on request.

CAMBRIDGE AND DUBLIN.

In the time of the Civil War, the Roundheads, so far as history can be trusted, used to give themselves and their companions some peculiar names. A similar fashion ought to be in vogue now, in order that appropriate cognomens might be given to so-called consulting electrical engineers. Several of these gentlemen would grace the name of "Never-have-a-mind-of-your-own," "Wait-to-see-what-turns-up," "Jump-with-the-last-speaker"; names not euphonious but eminently suggestive.

The history of the electric lighting proposals at Cambridge, for example, would ensure a knotty problem as to the most appropriate name for the adviser—we cannot say for the electrical engineer, because that term implies, at any rate, a thorough knowledge of information which, in the present case, is conspicuous by its absence. Let us get at once to our text. Are specifications intended to guide contractors or are they not? Are those who prepare tenders to take trouble and go to considerable expense, to find in the long run that their tender is put aside, the specification being changed and changed, till no one would recognise it, and some person or firm who did not tender upon the original specification is given the work? Is not this very much like what has happened at Cambridge? Here we have the professor-consulting-electrical-engineer pitchforked into a post because—well, because kissing goes by favour, and Cambridge probably wanted to recognise one of her sons, not without repute during his university career, and who, at any rate, has lately developed into a fluent and ready writer. Whether Cambridge has solved the question as to what volume of writing constitutes an electrical engineer, we know not, but this we do know, that a specification was prepared for the Cambridge lighting, that at considerable expense and trouble tenders were prepared, and then, lo, the weathercock mind finds the specification needs vital amendment. A visit to an installation seems to make a sudden impression as to its superiority over everything else—hence the post haste change, and now everything is to follow in the wake of this very superior installation. Who is to pay for the trouble and expense of the original tenders? Of course, we know that, as matters now stand, the various firms that tendered will have to bear a loss which is absolutely due to the indecision or to the ignorance of the man who framed the original specification. There is no need to beat about the bush, or to say words that will bear two meanings. We most distinctly wish to convey the idea that an engineer who permits this sort of thing is incompetent, and should not be entrusted with work that requires special knowledge and skill. A specification when made public, and upon which tenders are asked, should not require modification, or only in minor details that will not affect a tender or put it out of court. We do not expect a Baker, or a Mansergh, to issue specifications that delude contractors, and an electrical engineer's work is not so difficult as theirs. We should expect an engineer of

Max am Ende's attainments to repudiate with scorn a suggestion that a well-considered specification, say, for a gallery or an ordinary bridge, would require total alteration, because its author had seen or heard of another gallery or bridge. It is the duty of the consulting engineer to know what has been done in particular directions before he issues his specification, and not find out afterwards that he has issued it in ignorance.

A man may be a fluent speaker, a facile writer, and a capable teacher, and at the same time an incompetent engineer. As a rule, professors do not make the most competent practical men. They are imbued with the value of theoretic perfection, and cannot shake off the feeling that what they do must be perfect—that is, theoretically perfect. They cannot understand that theoretic perfection and practical usefulness are often as wide as the poles asunder. When a professor can throw aside this peculiarity he can, and does often, make a competent engineer, but when he does a little at teaching and a little at engineering, he is like a fish out of water, incapable of showing his true natural powers. The true course to pursue is to stick to one thing or the other, and not attempt the *rôle* of Jack-of-all-trades.

There is another problem underlying this question of specifications, and that is connected with wheels within wheels. It is frequently intended that the work shall go in a certain direction, and wire-pulling extraordinary takes place behind the scenes. The delay and discussions at Dublin lead us to believe that something of this kind may be contemplated there, otherwise it surely cannot have required day after day and week after week to decide as to the firm which is to have the contract.

LONDON LIGHTING.

On Tuesday last the formal commencement of the work in connection with the City lighting took place, the Lord Mayor laying what may be termed the foundation stone—this being a stone at the grand junction. We understand that the whole system will be carried out as one enterprise, and that the generating stations will, so to speak, be interchangeable. This is as it should be, as instead of divers interests there will be but one interest to command—the syndicate under which the work is done. With the Thomson-Houston apparatus on the one side and the Brush on the 'other, there is little fear of trouble. Both firms have carried out excellent work, and the development of each has shown keen commercial perception acting as guide onwards and upwards. According to our information, the Callender system of underground mains is to be used, and here, again, we come to a firm that has had considerable experience with work in the streets of London. Altogether the outlook is favourable, and still more so if we consider what an impetus will be given to the manufacture of all electrical accessories. Taking the most moderate estimates, the outlay upon wiring and fittings must reach to at least six figures within the next few months, and this work will be distributed among a large number of firms. The street lighting, as we have so often pointed out, is but a commencement of the work, and the part that will ultimately be least appreciated. It is the interior lighting that is the main object, and the one that will prove most advantageous to the combined syndicate and to the public. Before, however, we can have interior lighting the authorities must necessarily permit the breaking up of streets. And as the lighting by gas has long been voted bad, the authorities decided that the very best course they could take would be to arrange first for the proper illumination of the streets of the metropolis of the world.

CORRESPONDENCE.

"A NEW INSTRUMENT HAS BEEN INVENTED."

To the Editor of the Electrical Engineer.

Sir,—So you say in a paragraph, page 108, of your last issue, where reference is made to Mr. Reginald Jones's "very simple little piece of automatic apparatus"; but on page 126, in Mr. Bromley Holmes's paper, I find something of the same sort described as "a special apparatus devised by the author for this purpose"—viz., making continuous tests of insulation resistance.

Fancy your forgetting Edison's red and green lamps of years ago!—Yours, etc., Wm. H. Massey.

25, Queen Anne's Gate, Westminster, 3rd Feb., 1891.

INAUGURATION OF THE WORK OF THE ELECTRIC LIGHTING OF THE CITY OF LONDON.

The first practical step in what has been so long delayed and so anxiously looked forward to—the public electric lighting of the City of London—took place with due ceremony on Tuesday afternoon, when the Lord Mayor placed in position the first stone of the grand junction-box of the two systems which together are to supply electricity to the whole of the City. The place of this junction-box is in Walbrook, close under the walls of the Mansion House.

It is well enough known to our readers that the whole extent of the City has been divided into three districts. The contracts for two of these (the central and western divisions) have been obtained by the Brush Electrical Engineering Company, comprising a little over half the total area, and for the other (that east of the Mansion House) by the Laing, Wharton, and Down Construction Syndicate. Contracts on so large a scale were felt beyond the powers of the electrical companies without further capital, and at first it was proposed to promote different companies for the two concessions. The wiser course has, however, been taken of amalgamating the two proposed companies into one, so as to obtain the double advantages of direction from one central office, and of having a junction between the two systems of distribution in case of accident or need of aid by either of them. A pioneer company has therefore been formed under the title of the City of London Pioneer Electric Lighting Company, with, it is understood, the powerful backing of the Rothschilds and the Lord Mayor, with an extremely strong board of directors, including the Duke of Marlborough and the Earl of Suffolk and Berkshire, together with certain of the directors of the two contracting companies. When this company has carried out the definite contracts now entered into with the Commissioners of Sewers, and has works in going order, the large work necessary for the private lighting of the whole of the City will be undertaken, the large company having definite concessions and plant and works, will be able to go to the public for the necessary capital. It is this company's junction-box of happy omen that the Lord Mayor was called upon to inaugurate.

Pushing through the crowd of spectators which had congregated out of Cheapside in Walbrook, kept in place by a cordon of police, a large group composed of electrical and financial leaders, with the members of the Honourable Commissioners of Sewers and the City officials were seen peering into a large hole in the ground, decorated with crimson cloth and surmounted by a small derrick. This was the situation of the junction-box, in which large casings of Callender bitumen for the mains ended, and lined inside with white brick, while swinging from the derrick, ready to be laid, was the first stone, with the inscription :

THIS STONE WAS LAID BY
THE RIGHT HONOURABLE ALDERMAN JOSEPH SAVORY
LORD MAYOR
ASSISTED BY MR. DEPUTY FRANK GREEN
CHAIRMAN, AND THE MEMBERS
OF THE HONOURABLE COMMISSIONERS OF SEWERS
IN COMMEMORATION OF THE COMMENCEMENT
OF THE WORK OF LIGHTING
THE CITY OF LONDON BY ELECTRICITY
3RD FEBRUARY 1891 A.D.

Contractors :
The Brush Electrical Engineering Company, Limited.
The Laing, Wharton, and Down Construction Syndicate, Limited.

The Lord Mayor, who attended in his scarlet robes of office, having inspected the work, the Chairman of the Commissioners of Sewers introduced Lord Thurlow, P.C., F.R.S., the chairman, the Duke of Marlborough, and the other directors of the Brush Company, and Colonel Martindale, R.E., C.B., chairman, and the other directors of the Laing, Wharton, and Down Syndicate. The Lord Mayor pulled the cord and released the stone, which fell with a dull thud into its place—rather suggestive, in fact, of a graveyard ceremony—and declared the stone to be well and truly laid.

Mr. Deputy FRANK GREEN, in asking the Lord Mayor thus to inaugurate the first practical step in the lighting of the City of London, pointed out the immense importance of the character of the work they were now beginning. It was in March, 1878, that the question of lighting was first referred to the Streets Committee of the Commissioners of Sewers, and since that time no less than 39 reports had been sent in for the consideration of the Commissioners. This he mentioned as showing that the authorities had given no meagre attention to the interests of the ratepayers of London. One name he would like to mention, that of Mr. Pannell, as one of the most strenuous in constant endeavour to bring the question of the electric lighting of the City to a successful issue. Much also was due to the contractors for their liberal views in meeting the wishes of the Commissioners. They were now within measurable distance of the time when London should be the best lighted city in the world, as it was the best scavenged. He would like to take the opportunity of recognising the zeal, energy and ability of the officials and engineers of both companies, and of the solicitor, Mr. Bates, whose work in passing the Bills had been considerable. The wishes of the Commissioners were to obtain the best for the City, whose streets were under their charge, that was possible to be achieved.

The LORD MAYOR said it gave him peculiar pleasure to be the motive power to lay the first stone of the City of London Electric Light Works in its place. It had often been said that London was backward in introducing the electric light in its streets, but he considered it had done well to wait and take the advantage of experience, so as to be certain when it was done to have a good and thorough system. He looked upon the present step not as a revolution, but an inauguration of immense improvement ; and the union of the companies which are to carry out the work was well symbolised by the chamber of union erected in such happy proximity to the Mansion House. He felt great satisfaction that the inauguration of such an important step had taken place during his period of office, and congratulated Mr. Deputy Green upon the happy termination of the labours of the Commissioners of Sewers. He hoped it might be possible for them to do as much for the dispersion of fog by electricity in the future.

Lord THURLOW thanked the Lord Mayor, and handed, in memento of the occasion, an inkstand formed of silver-mounted specimens of the cables to be used in the mains.

Colonel MARTINDALE presented a similar memento to the Chairman of the Commissioners of Sewers.

The visitors invited to the ceremony then trooped off to Cannon-street Hotel, where an elaborate luncheon was served, the Lord Mayor, owing to a previous engagement, being unable to attend, and Lord Thurlow took the chair.

Colonel MARTINDALE, in proposing the toast of "The Honourable Commissioners of Sewers," alluded to the incessant work of this body in bettering and widening the streets, and said it was owing to the exhaustive enquiries which they had made, together with the best scientific intellects of the land, amongst them Mr. W. H. Preece, chief engineer to the Post Office, that they had been able to obtain the best installation of electric light in England.

Mr. Deputy FRANK GREEN, in responding, said that one of the greatest difficulties in the question of electric light, or any other improvement, was the consideration of the interests of the ratepayers. They had to steer between the legitimate demand of the public and the calls on the pockets of those who pay the cost. They had held their hands until a system as nearly perfect as possible had been presented to them. It must not be forgotten that some years ago street lighting was tried as an experiment. This experiment cost them £8,000, so that it would be seen that even at that time they were desirous of lighting the City by electricity. Since then electric science had advanced with giant strides, and now that the system had been decided upon the contractors need not fear that any obstacle would be placed in the way of co-operation.

The DUKE OF MARLBOROUGH said it gave him great pleasure in proposing success to "The Electric Lighting of the City of London." For many years he had been connected personally with electric lighting, both in this country and in America, and he was greatly pleased to be now connected with a system of such large potentiality. In the City of London was congregated the greatest wealth the world possesses, and to light successfully the enormous number of houses in its area demanded the utmost consideration. The fact that London was liable to suffer from periods of darkness in the daytime threw greater strain upon such an undertaking than in any other city. The remarks as to caution he considered most opportune. He remembered going with several gentlemen, with the late Mr. Ladd, to see the first Brush arc lamp exhibited in England, which was run on the site of the Grecian Theatre. He might say with great prudence, that owing to the careful deliberations of the progress since that time, that the present undertaking was going to be a thorough success. For one thing, the present scheme was not too ambitious, and they were not in a position as to be not quite certain as to what they could or could not carry out. The only thing to be feared was the narrowness of the streets in some places, where there might be some difficulty in avoiding gas and other pipes, but from what he had heard from the engineers this would not be insurmountable. When the work of the Pioneer Company, over which the Lord Mayor has consented to preside, has been concluded, he thought there would be no difficulty in asking for the money for a complete system. He was glad the work had been able to be placed in the hands of a single company. In this their action was opposed to that of the Board of Trade, who encouraged two companies and two sets of mains in the same district. It was his opinion that this must result in loss both ways, either by fighting and loss to the shareholders, or in amalgamation, in which case double the necessary mains would have been laid. In their case they had carefully calculated the extent of the demand, and arranged their mains accordingly. When finished he thought they would be in possession of a more successful system than any other yet undertaken.

Mr. PREECE, in responding, said he felt within measurable distance of the fulfilment of the wishes of his life—the lighting of the City of London by electric light. He had other wishes which had not seen so successful an issue. Instead of castles in the air, this might be said to be a castle in the ground. When he had taken part in that funereal ceremony they had attended that afternoon, he thought as he saw therein the products of General Webber's inventions:

> "Not in ohms nor in volts they wound him;
> But he lay like a warrior taking his rest,
> With his bitumen casing around him."

One of the things they had paid most attention to in designing the system of supply was that of safety. He could confidently say that not one point had been neglected in the system of lighting the City to provide for the greatest possible safety. It had been mentioned that £8,000 had been spent already in electric lighting in the City. It was nearer £12,000. Indeed, he could say that up to the present time there was no corporation that had actually spent so much money in electric lighting as the Corporation of London. Since their first experiments the first cost of the plant had become nine times cheaper. The cost of manufacturing electricity was now cheaper than that of manufacturing gas. It was not so cheap to distribute. This was owing to the sale of waste products, but there were towns in America where they are not able to utilise their waste products, where the manufacture and distribution of electricity is actually cheaper than that of gas. He had visited all the principal towns yet lighted by electricity —Chicago and New York and Boston, Rome, Milan, and Paris—yet he could truly say that when the contracts were carried out the City of London would be the best-lighted city in the world. He hoped in times of celebration they would put up the motto "The light of other days has faded."

The health of the contracting firms was then given.

The following are the official particulars given of the contracts:

The streets will be lighted in all by 400 arc lamps of 2,000 nominal candle-power, and 1,000 incandescent lamps of varying candle-power, absorbing from 100 to 200 watts per lamp, while the arcs are to be 10-ampere lamps, absorbing 500 watts each.

The provisional orders granted to the above-mentioned two companies contain many special features, and under the contracts entered into with the Commissioners of Sewers the companies will light every street, lane, court, and alley, and will obtain what is practically a monopoly of private supply.

The cost to the City of London for the illumination of the whole of its streets by electricity will, when fully completed, not very much exceed £20,000 per annum, and for this the Commissioners will have probably 20 times the illuminating power at present obtained from gas.

The contracts with the Commissioners require that the works for public lighting shall be commenced before February 19 this year, and the ceremony to-day consists in starting the underground works, by constructing the main junction-box to be used for connecting the mains of the two contractors, the object being to make their systems interdependent, so that in the event of a serious accident occurring at either of the generating stations, current will be obtainable from the other station.

The site of the Brush generating station is on the south side of the Thames, and the mains will cross to the City over Southwark and Blackfriars bridges. The station will ultimately have a capacity of 600 2,000-c.p. arc lamps and 60,000 60-watt incandescent lamps, this being for the supply of the central division.

The generating station for the eastern division will be situated on the banks of the river between the Custom House and the Tower of London, and the Laing, Wharton, and Down Construction Syndicate have designed the plant to have an ultimate capacity of 600 2,000-c.p. 10-ampere arc lamps, and 120,000 35-watt incandescent lamps.

The systems to be employed by the contractors are already well known. The Brush Company will employ their well-known Brush apparatus for street lighting, and the Mordey-Victoria alternating-current dynamos and transformers for private lighting.

The Laing, Wharton, and Down Construction Syndicate will employ their well-known Thomson-Houston apparatus, both arc machines and lamps, for public lighting, and alternating-current apparatus for private lighting.

The systems of both contractors have already been extensively employed in America for many years, as also on the Continent, and since the amendment of the Electric Lighting Act of 1888, in this country.

LITHANODE ACCUMULATORS.

Lithanode is a term invented by Mr. Desmond FitzGerald to fit the discovery made by him of a method of moulding secondary battery plates out of litharge in slabs as solid as stone (Greek *lithos*, a stone)—stone anode—or, shortly, lithanode.

The name is sufficiently familiar to electrical engineers who have given some attention to Mr. FitzGerald's invention, the new type of cell having been brought forward some few years ago by the Union Electrical Company, whose operations were, however—owing to financial rather than electrical reasons—brought to a conclusion, and the invention was taken over by the Mining and General Electric Lamp Company.

This company has been busy perfecting an electric portable miner's lamp of about the same weight as an ordinary safety-lamp, and in making elaborate experiments with and tests of the lithanode battery, in conjunction with Dr. Frankland, F.R.S., who is one of the directors, and under the immediate supervision of Mr. FitzGerald, who is consulting electrician to the company. Many practical details of the construction of the miner's lamp have been worked out by the manager, Mr. Moscrop, and valuable aid in the proper proportioning of the constituents of the batteries has been given by the electrical engineer in charge, Mr. Hough, who was formerly with Sir F. Bolton.

Arrangements have now been made for the manufacture, on a practical scale, both of the light portable miner's lamp and also of an ordinary type of secondary cells for stationary and traction use very much lighter in weight for the capacity than any now made. The miners' lamps have been on exhibition this week at a mining exhibition organised at the Institution of Civil Engineers. The larger types of lithanode cells are being fitted to a private launch, and are being supplied for lighting purposes to several private installations. It may, therefore, be interesting to present our readers with as full particulars as are obtainable of this invention, which is one, we may remark, that certainly seems to promise a very extensive revolution in secondary battery manufacture.

The ordinary manufacture of accumulators, as at present achieved, is done upon engineering principles and for engineers. The users of secondary batteries in electric light installations are content, in most instances, if a practical storage of electrical energy is rendered possible with a fair workable return in output, and the weight is not of absolute first importance. In traction work the case is altered, and weight as compared with capacity is a necessary consideration. Much more is this the case in portable batteries for such articles as miners' electric hand lamps.

The usual type of accumulator has, when applied to delicate work, the following disadvantages:

1. Local action is unavoidable between the lead support and the peroxide of lead, the peroxide being converted into sulphate of lead, and the lead support also running down into sulphate. In large batteries, though this is a disadvantage, it is relatively far more so in small ones.

2. There is often no just proportion in the ratios of the various constituents of the battery.

3. The battery as a whole is unnecessarily heavy. The manufacturer of large cells detests all niggling, delicate work, and does not aim at perfection, and a compromise is accepted in practice.

In portable batteries, and in batteries for traction purposes, the weight is required to be reduced as much as possible, and careful attention to everything that can conduce thereto is very necessary. To achieve this, the weight of the elements and the weight of the electrolyte must be reduced as much as possible. To obtain the best result, the three elements, anode, cathode, and electrolyte, must be accurately proportioned to the chemical reactions. There must be no excess of peroxide, but little of spongy lead, and little or none of the electrolyte.

The lead supports which are necessary to afford a conducting frame to the peroxide occasion much of the excessive weight of secondary cells. For some inscrutable reason it has always been assumed by makers of secondary batteries, and Mr. FitzGerald himself had long been under the same impression, that for the cathode also lead was practically the only material that could be used as the support to avoid chemical reaction. For the peroxide plate it certainly is the only support available except platinum or iridium, both impossible in practice on account of their excessive cost. But for the spongy lead there are several other conductors which might advantageously replace lead with much less weight. One such conductor has been found in copper, which is preferably coated with lead. In the new cells made by the Mining Electric Lamp Company under FitzGerald's patents, the support for the spongy lead plate is formed of a double network of copper gauze dipped in lead, upon which the active material is compressed in a solid block, affording a perfect support, and the total weight of the spongy lead plate is reduced in the proportion of 3lb. 10oz. to 7lb.—*i.e.*, is hardly more than 50 per cent. of the ordinary plate. In a complete cell, the glass containing cell, electrolyte, and peroxide plate being of the same weight as before, this improvement alone gives a gain of 15 to 20 per cent. in the total weight of the cell.

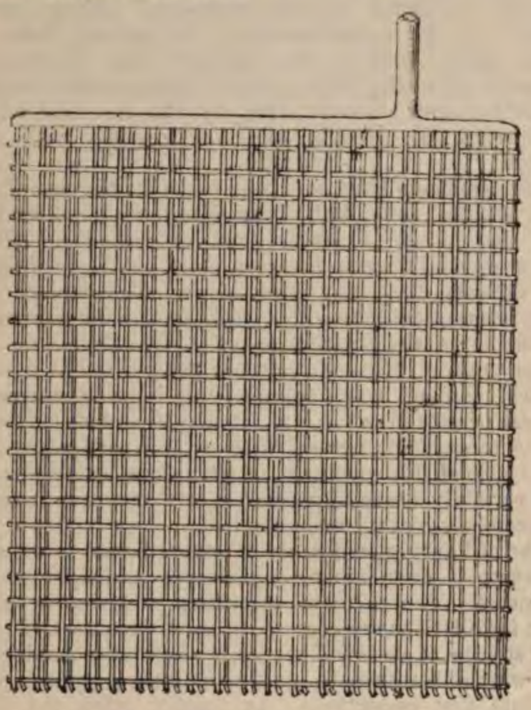

FIG. 1.—**FitzGerald's Copper Frame for Spongy Lead Plates.**

We have not yet spoken of the essential and major invention of Mr. FitzGerald, the formation of the lithanode plates.

The attempt has been several times made to form the peroxide plates out of compressed litharge, or even out of compressed peroxide of lead. The difficulty that has stood in the way of practical manufacture has been that these plates of compressed material would not keep their consistency, but eventually fell to pieces and crumbled away when placed in water or in an acid electrolyte. Dr. Frankland's process was an improvement, inasmuch as it introduced a chemical action, the plates being made by mixing litharge with sulphuric acid and then moulding it into blocks under compression. In this method the chemical action is too sudden and the result not perfect.

Mr. FitzGerald's lithanode is produced from a mixture of litharge with certain other chemicals, in which the chemical action is very gradual, giving the particles time to range themselves, and the resultant material is very homogeneous and becomes a hard and solid block.

In the process of manufacture the litharge and other chemicals are weighed out and mixed with solution into a paste, and transferred immediately before it has time to set (which it at once commences to do) to a die-plate of the form of the element required. This is placed under an hydraulic press and subjected to a pressure equal to that of 1½ tons per square inch. These plates or blocks are then placed in racks to dry and gradually consolidate. They are usually left thus to season for a fortnight, but can be used in two or three days if need be.

The next process is termed "browning." They are subjected to a special preparation, which coats them with a superficial skin of peroxide. If placed without this preliminary process in the forming bath the peroxide would begin to form in spots, and it would be very long before the whole material was attacked and converted to peroxide. Whereas, after being "browned," action takes place all over the surface, and the conversion goes on regularly till the whole plate is changed into peroxide of lead. Formerly, this process used to take a fortnight to accomplish, but by improved methods is now brought about in four or five days. The proportion of peroxide in the lithanode plates has varied—not all of the substance is converted into pure peroxide. There is always a little sulphate, but in the present process over 90 per cent. is converted. It would, no doubt, be possible, though difficult, to overcharge the lithanode and convert the whole into peroxide, but this, even if done, would decrease its hardness while increasing its fragility. A slight amount of sulphate seems to be necessary to ensure strength of plate.

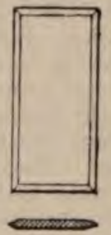

FIG. 2. Lithanode Slab.

For the small plates of the miners' lamps these lithanode blocks or plates are very closely attached to a strip of platinum foil. Three ebonite screws are inserted in the body of the plate, and the platinum foil, backed by a strip of ebonite, is tightly screwed by ebonite screws to the back surface of the lithanode. A lead plug connected to the platinum serves as terminal. The spongy lead of the miner's cell is supported, as explained above, upon a network of copper. The result is that the lithanode secondary cell is somewhere about 50 per cent. less weight for the output than any type of paste and grid cell at present made.

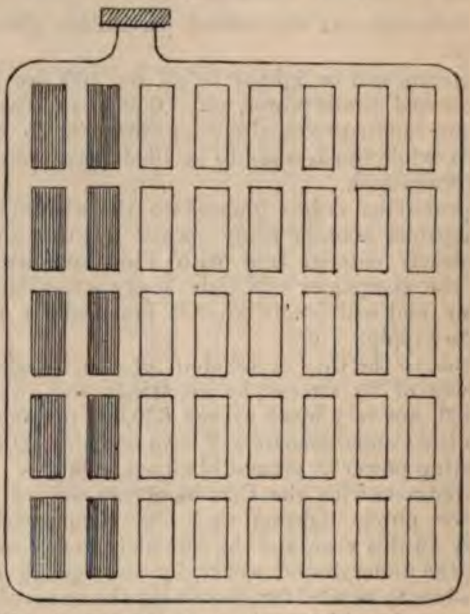

FIG. 3.—FitzGerald-Frankland Lithanode Plate.

The mining lamp is now being made in considerable quantities. It is an entirely practical lamp made for the hands of miners, and embodies many little points of detail carefully worked out from the point of view of ease and cheapness of manufacture and resistance to rough usage. The principal thing to notice in the lamp, as distinct from the cell, is the outer casing, which is of thin steel surrounding the cell and leaving a slight air space all round the cell, being kept in place by indiarubber knobs inside. This arrangement gives a cheap and exceedingly effective protection to the lamp, any accidental knocks being received on the elastic surface of the steel casing without destroying the cell. The lamp is an ordinary small Edison-Swan lamp mounted with a projecting cover of toughened glass. The weight of the lamp is 3lb. 4oz., burning for 12 hours, and gives the light as of 1½ to 1 of the latest type of Muesler lamp, the Marsaut improvement. It is almost exactly the same weight as this lamp, or even a little less. A larger type of lamp gives double the light of the miner's lamp and weighs 4lb. It is intended for use in ships' holds, gas works, and other places where a stronger light is required and the extra weight is no objection.

The larger cells which the company are manufacturing for stationary work are, in fact, a combination of the lithanode and the copper-net framework plates, with the method of casting grids patented by Dr. Frankland. The lithanode blocks are moulded and pressed in large plates like chocolate cakes, and broken up afterwards into pieces of the shape shown, with bevelled edges. The pieces, after they are partly "formed," are placed in a mould and the lead grid cast around them, giving a battery plate of the shape indicated in the illustration.

The plates are alternated in the complete cell with thin plates of lithanode material compressed on the copper net.

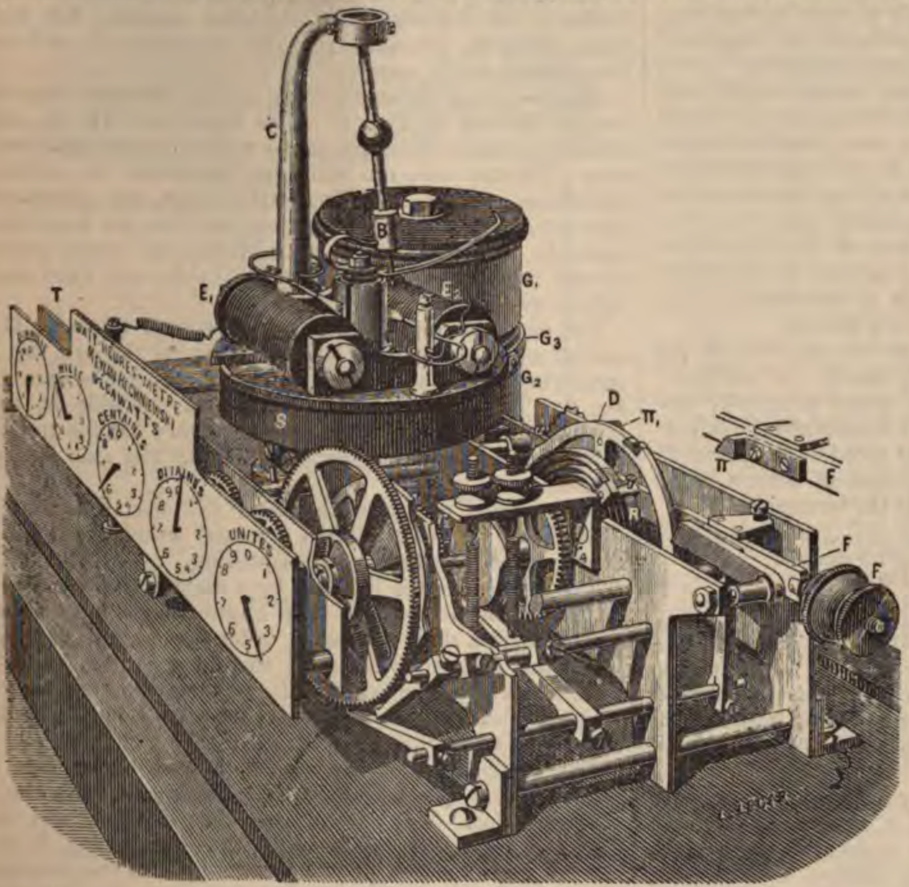

Fig. 1.—Meylan-Rechniewski Electric Meter.—General View.

The cells have been tested continually by Dr. Frankland, and the results show, for instance, in an ordinary size cell a diminution in weight of 15 to 20 per cent. Thus the ordinary E.P.S. L type, weighing 75lb., gives 120 ampere-hours. The new Lithanode-Frankland cell yields 200 ampere-hours for a weight of 73lb.

The works of the Mining and General Electric Lamp Company comprise a 18-h.p. semi-portable Wallis-Steevens steam engine, driving through countershafting low-pressure dynamos for charging. The principal dynamo is a Crompton machine capable of giving 950 amperes at 12 volts, though it is not generally used over 750 amperes. A second Crompton dynamo, giving 450 amperes at six volts, is also used, and an Elwell-Parker dynamo, giving 250 amperes at six volts, is used on the acid baths. On the same floor are fitting-shops, and a long room for charging and converting the plates. Above is the laboratory, and testing-room, and moulders' room, with dies and hydraulic presses. Another building has just been erected for the manufacture of the larger cells. The company seem to be laying themselves out for practical supply of lithanode plates, and we shall be greatly interested in the future of these batteries.

THE MEYLAN-RECHNIEWSKI ELECTRIC ENERGY METER.*

BY E. MEYLAN.

(*Concluded from page* 121).

We hope to obtain better results by using a more robust piece of machinery in the shape of a Gramme motor, which gives no sparks and has no dead point. To adapt it entirely to our needs it is sufficient to add two arrangements—one destined to make the starting certain, the other to regulate the speed.

A motor taking a constant current, supplying the very variable work necessary to take the readings and giving at the same time the time factor, has, furthermore, the advantage, by no means negligible, of being able to be inserted directly in the shunt circuit, which is needed for the wattmeter, so that in this way one shunt circuit is all that is required.

We have indicated the motives which have guided us in the choice of the two principal parts of our meter; it remains to discuss the arrangement for registering and integrating the readings. But here we are not dealing with general principles; all that can be said is that the arrangement must be as simple as possible. We shall indicate this mechanism in the detailed description of our instrument, to which we now pass.

The Meylan-Rechniewski meter, of which Fig. 1 gives a general view, comprises six principal parts:

1. An electric motor, M, Fig. 2, with permanent current and constant speed.

2. A train of wheels, reducing the speed of the motor and communicating to a final or principal axle, A, Fig. 3, a strictly uniform and continuous rotation, of which the speed is one-third revolution per minute.

3. An electro-dynamic balance—a wattmeter formed by one or two fixed coils, G_1 G_2, traversed by the main current, and a movable coil, G_3, fixed to a beam, F, mounted upon a pivot or upon knife-edges; this balance gives rise, under the action of the main current and the shunt current, to a force proportional to E I, a force which is balanced by a fixed counteracting force.

4. An elastic cam; this is the part of the apparatus which works the readings of the balance.

5. A gearing arrangement controlled by two detents, communicating to the first moving part of the totaliser, T, the movement of the principal axle during the period of each reading of the balance. The action of the detents is dependent upon the movements of the principal axis of the elastic cam.

6. A totaliser, whose various dials show in hecto-watts the consumption of energy in the circuit upon which the meter is connected.

Constant Speed Motor.—The motor which we have at last settled upon is of rather a special type. Fig. 2 gives a section and partial elevation which will serve to make its action clear.

It is a disc motor, but one in which the two field magnet poles are on the same side of the armature, that is to say, above this latter; this arrangement gives rise, as one may see at once, to a real uplifting of the armature core under the action of the magnetic field. This considerably relieves the jewel upon which the pivot rests.

The field magnet system comprises two semi-circular pole-pieces, connected together with two square pieces fastened by two bolts, which form the cores of the two electro-magnets, E_1 E_2, Figs. 1 and 2.

---

* Translated from *L'Electricien.*

The armature is a flat ring of iron, insulated and wound with 3,000 turns of fine wire, forming five or six segments, connected to an ordinary commutator. This armature is carried in an ebonite support, mounted upon the axis, V, whose endless screw works the wheels, $r_1 \ . \ . \ . \ r_4$, Figs. 1 and 3.

The field magnet is fixed to the pillar or standard, C, which also carries one of the brushes, $\beta +$. The second brush is held by an insulating support. These brushes are formed by an elastic wire terminated by a flat pinch of silver wire of ·15 or ·2 millimetre diameter.

This arrangement is both simple and easy to put together or take to pieces; all that has to be done is to loosen a screw, draw out the upper part of the standard, and then remove the nut which holds the lower pole-piece fast against its supporting piece.

The armature spindle passes through a socket and guide which forms part of the framework of the mechanism (see Fig. 3).

The system of regulation of which we have spoken consists in periodically shunting the coils of the armature. This result is obtained very simply by connecting one of the commutator plates to the insulated passage which pulls round the conical pendulum which we use as speed indicator. One of the brushes ($\beta +$) being itself connected to the ball of this pendulum, it can be seen that when the ball, B, touches the contact, c, a part of the shunt current passes outside the armature. For instance, when the plate is under $\beta -$, the current goes by way of X, C B, $c \beta -$ to the field magnet, I, without passing through the armature. On the other hand, when this plate is beneath $\beta +$, the shunt current passes entirely into the armature.

On an average, a decrease of about 50 per cent. of the motor energy is thus produced, which is sufficient, generally speaking, to maintain the speed practically constant within fairly large limits. We have taken the following readings of the variations of the speed of the principal axle connected to the motor by a train of wheels, while varying the difference of potential at the terminals :

Difference of potential.	Time of 1 revolution of principal axle.
87 volts.	181·5 seconds.
91 ,,	180·3 ,,
96 ,,	179·3 ,,
100 ,,	178·3 ,,
104 ,,	177·5 ,,

That is, for a variation of 17·7 per cent. of the volts, the variation of speed was only 2·2 per cent.; in the practical limits of electric lighting, even with a total variation of 10 per cent., the maximum possible error under this head would be only about 1·5 per cent.

The sparking at $c \beta$ is absolutely invisible, for it only takes place from the breaking of a circuit traversed by ·025 ampere; moreover, the contact is always perfect; and, lastly, the current is never entirely broken, as is the case in the well-known arrangement of Marcel Deprez. On the other hand, it may be considered as practically constant when care has been taken to give the armature a resistance relatively small compared to that of the whole circuit.

The regulator has yet a further purpose, that of assuring a sharp starting of the motor by giving rise to a strong increase of the shunt current while yet the ball has not quitted its central support. This is brought about by a contact, c^1, connected with the axle of the motor, and consequently with its mass and the wire, f, with the outer extremity of a resistance, X—the other extremity of this resistance being connected to the standard, C. It is seen that so far as concerns the contact between B and c^1, the resistance, X, is shunted, and the shunt circuit then only includes the motor and the rheostat, R_1. The motor therefore rapidly gains its normal speed, and there is never the slightest fear of a misstart.

Here a spark is certainly observable at the breaking of the contact, c^1 B, but this effect in practice only occurring once a day, offers no inconvenience. It is hardly necessary to point out that a reading made at the moment of actual starting would be not correct, but here again this accident is practically negligible.

In the case when it is desired that the meter should act with very variable differences of potential, we employ a *double slotted way*, that is, a passage formed by two parts connected with two plates diametrically opposite.

The ball, B, arrived at the end of its course, becomes interposed between the two contacts in such a way that two plates of the commutator are always at the same potential as one of the brushes.

The diminution of motive power is then double what it is in the previous case, and the regulation is considerably more perfect. The following results were obtained under these conditions :

Volts at terminals.	Period of one revolution of motor.
140 volts.	39·1 hundredths of second.
112 ,,	39·9 ,, ,,
104·5 ,,	39·8 ,, ,,
98 ,,	40 ,, ,,
94 ,,	40·5 ,, ,,
90 ,,	40·5 ,, ,,
86 ,,	41 ,, ,,

From 90 to 140 volts, the variation of speed has therefore been 2·5 per cent. only for a variation of 50 per cent. in the potential.

Clockmakers may find, perhaps, these results not very brilliant; but we think that electrical engineers will find them sufficient, provided they can absolutely depend on the running of the motor.

Electro-dynamic Balance.—This part of the instrument is seen to the left in Fig. 1. The fixed coils, G_1 G_2, are formed by insulated copper strips wound on a central wood core. The two coils are connected sometimes in parallel, sometimes in series, according to the types, but always so that the actions are added together, and that the force acts upwards. The current is taken from two brass blocks pierced with holes, into which the cables are fixed and tightly screwed by a set screw.

The movable part is formed by a roll of fine wire, G_3, carried upon an ebonite support fixed to the arm by a metal ring riveted to this latter. This part can be seen in Fig. 3. The current is led to the coil on one side by the pivots, and on the other by a band of very flexible tinfoil, fixed upon an insulating support near to the axis of suspension.

In the small model of the meter the arm, F, is simply pivoted at $p \ p$; but to obtain a greater sensibility it is advisable to adopt a knife-edge suspension.

The movable coil is balanced by a counterweight screwed to the end of the arm, F. This counterweight must be regulated with a slight excess, in order that even in the case when the electric force is nil there may yet be a certain force to act upon the arm to raise it, this, of course, constituting a false zero, which is taken account of in the registration, as we shall see.

The engagement of the arm, F, by the elastic cam is brought about by a piece of steel, π, fastened to this arm.

Elastic Cam.—The elastic cam, Fig. 3, comprises the disc, D, carrying the steel cam, π_1, the spiral spring, R, the axle, A_1, and a clutch, L, which connects it to the principal axle, A. The axle A_1 is carried directly on the end of A between points or on pivots. While the cam π_1 does not meet the piece π of arm F, the spring R is not twisted, and the shaft A_1 participates in the movement of the axle A.

At the moment of contact, on the contrary, the cam is stopped and the spring is twisted through an angle proportional to the pressure that the arm exercises originally upon its acting end. At the moment when the cam raises the arm the reading is finished.

Friction Gearing and Detent.—The movement being uniform, the sum of the torsions will make the sum of the times of reading. To obtain this it is necessary to couple the axle A with the first wheel of the totaliser, T, during the periods of torsion. For this purpose we have constructed a friction gear, controlled by detents, of which one is set in action by the actual movement of the principal axle, and determines the *true origin of the reading*, while the other is dependent on the movement of a click, and *set in action by the active force of the elastic cam* at the end of the reading, and putting an end to the gearing at this moment. This arrangement necessitates, therefore, that for the zero reading there should already be an active force—that is, a certain torsion of the spring, R; the counterweight, P, must exercise an excess of pressure upon the fixed end of the lever, F, as we have mentioned.

The following is the manner in which we have constructed this gearing of periodic but variable duration, all the parts of which are represented in Fig. 3. A ratchet wheel of large diameter, r, is mounted with weak friction obtained by the pressure of bent washers at the extremity of the axle A; it draws round the first wheel of the totaliser, T, by means of a stud, t, which pushes a slide belonging to this first wheel.

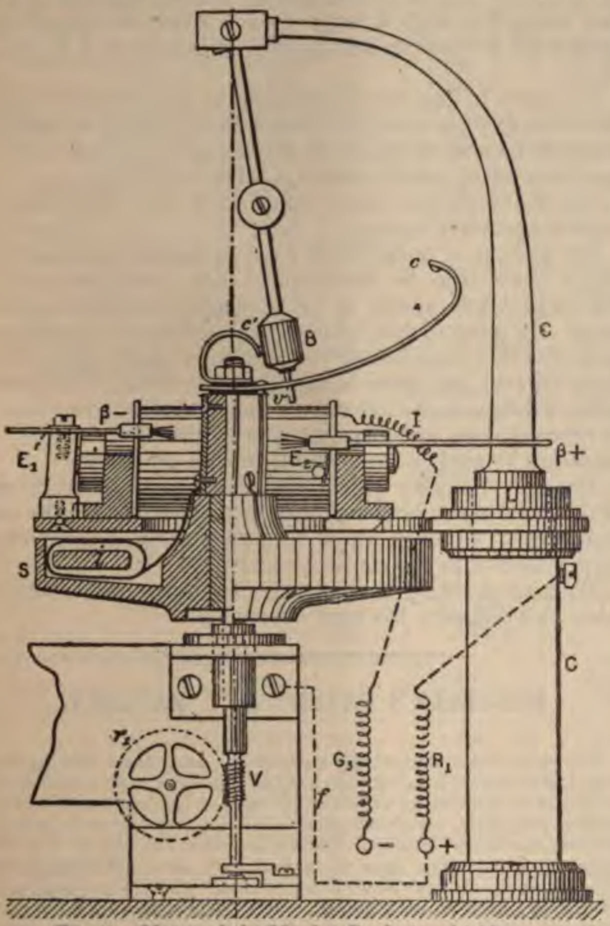

Fig. 2.—Motor of the Meylan-Rechniewski Meter.

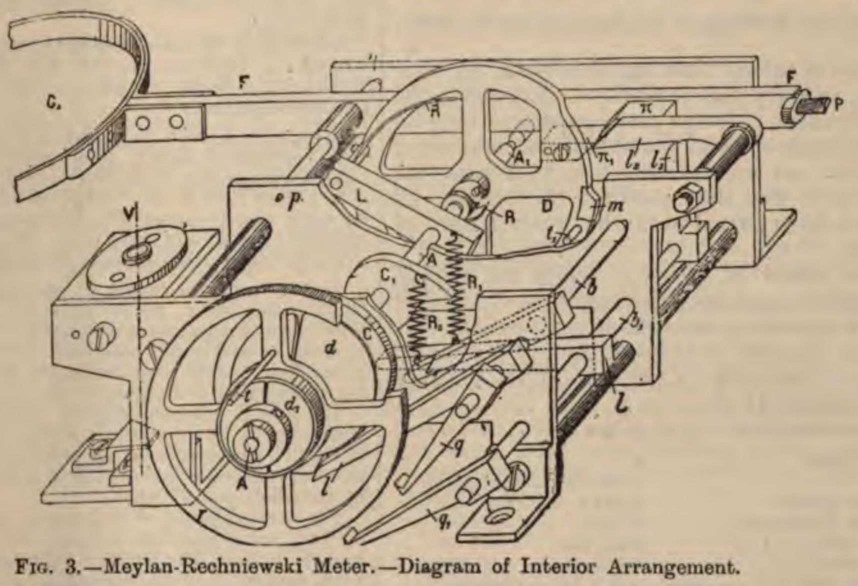

Fig. 3.—Meylan-Rechniewski Meter.—Diagram of Interior Arrangement.

This ratchet wheel, r, is furnished with two detents, $q\ q_1$, the first of which is always engaged before the commencement of the reading, and is liberated at the moment when this begins; while the other, q_1, which is normally disengaged, becomes so the moment the reading finishes.

For this purpose the first detent, q_1, which is fastened to and works with the axle b_1 and the lever l, is governed by the cam c, whose shape and the wedging effect upon A are such that the detent is put out of action at the precise instant that the reading commences, while it is brought again into play at the end of the turn by the action of the spring R_2.

On the other hand, the detent q is fastened to and works with the axle b and the lever l_3, which is maintained in place against the action of the spring R by a notch on the lever l_2. When the reading is finished the piece π_1 of the spring cam escapes from the piece π of the beam. At this moment, and under the action of a preliminary torsion, and of the torsion corresponding to the extent of the reading, the disc, D, which is cut away on a portion of its circumference, becomes raised by m of the lever l_2; the lever l_3 escapes, and the detent q immediately comes into play under the action of the spring R_1.

At the end of the turn a second cam, c_1, also fastened upon the axle A, by pressing on the lever l_1 fixed on b_1 pulls back the ratchet wheel q_1 and the lever l_3 into their place while stretching afresh the spring R_1.

This last operation naturally does not take place until after the first detent, q, has been re-engaged by the cam c, so that the ratchet wheel is not free until the moment of the following reading.

The regulation of the instrument is brought about very simply by assuring the simultaneous freeing of the detent q and the re-engagement of the detent q_1, when the electrodynamic pressure is nil; this regulation is brought about by the position on the shaft of the cam c and the adjustment of the weight, P.

Connections.—As we have said, the motor is wound in series, and forms part of the fine-wire circuit of the wattmeter and a rheostat. The connections of the shunt circuit are therefore those of Fig. 2, of which X would represent a rheostat and R_1 the coil of the wattmeter.

Each meter carries four terminals; the two first to the left, which are insulated, correspond to the positive main, and the positive wire to the lamps; they are connected by the thick wire of the galvanometer. The two others, which together form one connection, serve to fasten the negative main and the negative lamp wire. The shunt circuit is connected on one side to one of the positive terminals, and on the other to one of the negative terminals.

Calibration.—The calibration of our instruments is made in such a manner that the first dial of the totaliser indicates a multiple or a decimal part of the electric unit of work, the hecto-watt-hour (100 watt-hours).

Thus, for meters of lower capacity (100-110 volts 12 amperes), one division of the first dial corresponds to a deca-watt-hour (10 watt-hours). This calibration is made, for a type once settled upon, by altering in the desired direction the total resistance of the shunt circuit, which is about 2,000 ohms, the speed of all our motors being regulated previously so that the rotation of the main axle is made once in three minutes.

Series of Types.—The capacity of a motor is determined by two conditions, of which one depends upon the measuring apparatus, and the other on the extent of the measurements to be taken—that is, on the number of lamps to register—if it is desired that the meter must register from a single lamp upwards.

In fact, if an instrument has a sensibility such that it can mark with the approximation desired from unity up to *n* times this value, it will be sufficient to proportion the galvanometer in such a way as to make the minimum electro-dynamic pull correspond to the energy consumed by each lamp to obtain a meter for *n* lamps.

It will be sufficient to modify the winding of the galvanometer to obtain the types for the smaller capacities. But it will be necessary, in order to satisfy a practical condition, that all the galvanometers used do not themselves consume more than a very small amount of energy.

It seems at first view that we should fix upon a certain limit of loss of voltage—0·2 volt, for example—and to give to the instrument a resistance inversely proportional to the maximum current. Nevertheless, as the electro-dynamic pull is proportional to the volume of copper and to the loss of energy, and as this increases as the current increases in constant loss of voltage, this loss of voltage can be diminished as the size of instrument increases, while still obtaining more powerful pulls, a condition necessary to obtain great sensibility.

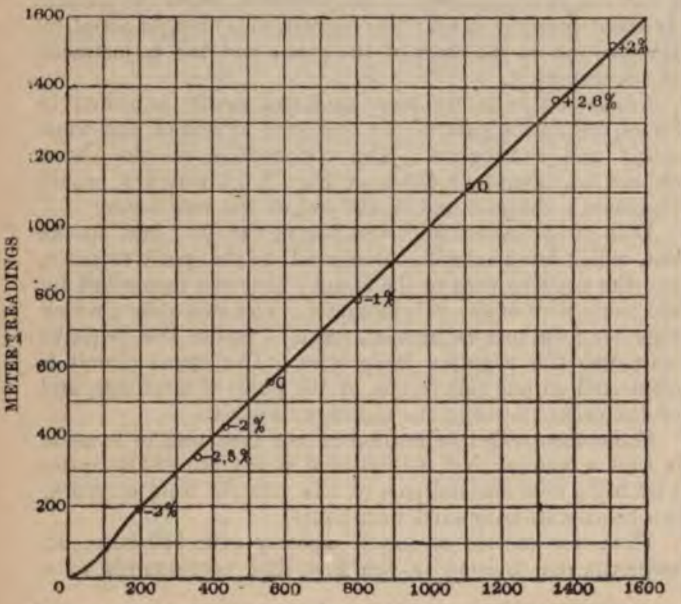

FIG. 4.—Watts Curve of Readings of Meylan-Rechniewski Meter.

The relative loss of energy thus decreases with the size. On the one hand, in every discontinuous reading meter, the sensibility or the range is always much greater as the size of the registering apparatus and the pull of the measuring apparatus is larger; we are led, therefore, to increase the size of the instrument with the capacity of the meters.

These principles have guided us in the establishment of our series of types.

Thus our first model of meter, of which the ratchet wheel has 300 teeth, measures from unity to 70 or 80; furnished with a galvanometer, whose resistance is 0·01 ohm, it forms our type of 12 amperes, and is capable of measuring from one lamp of 8 c.p. (30 watts) up to 40 lamps of 8 c.p., or 20 lamps of 16 c.p.

The principal constants of this type are :

Periodicity of readings......................	3′
Constant	1 division = 10 watt-hours
Resistance of shunt circuit	2,350 ω
Resistance between terminals............	0·01 ω
Maximum loss of volts	0·12 volt
Loss empty (100 volts)	4·5 watts
Maximum loss (100 volts 12 amperes)	4·5 + 1·5 = 6 watts
Maximum electro-dynamic couple	60 gramme-centimetres

It is easy to alter this type so as to measure up to 25 amperes by modifying the galvanometer, so that the maximum ampere-turns remain constant with the same weight of copper.

Our second type is capable of registering from one lamp up to 80 lamps of 8 c.p., or 40 lamps of 16 c.p.

For higher capacities it is necessary to increase the size of certain parts.

Fig. 4 represents the results given by a meter of type 2, the ordinates corresponding to the readings obtained on the meter, and the abscissæ represent the actual energy.

From an examination of this curve it is seen that with a meter constructed to register the consumption of 40 lamps of 16 c.p., it is possible to register the consumption of the first lamp, but with a large error. After five lamps are lighted the indications are correct within about 2 or 3 per cent.

The error in the total consumption will therefore be of this order (2·3 per cent.), on the condition that on an average a certain number of lamps are turned on at any one time, a condition which nearly always obtains in practice.

The readings have been taken from the meter during periods of several hours.

Our system of meter lends itself to various combinations which allow it to be transformed into a volt-hour meter, and its principle allows it to be applied to alternate currents. In point of fact, although the presence of the motor gives rise to a considerable retardation of phase (lag) of the shunt current, compared to the principal current, the electric balance does not give less exact results, while the frequency of reversal does not change; it will, therefore, simply be necessary to modify the rheostat in each given case.

The only difficulty which is presented is that by reason of this lag a much higher potential is required to make our motors act, although they do not sensibly absorb more energy than with the continuous current.

We shall probably have occasion to return to this subject when this difficulty has been overcome.

HELLESEN'S PATENT DRY BATTERY.

The want of an efficient dry battery has long been felt in both telegraphic and telephonic services, and perhaps even more for use in houses in connection with electric bells. After numerous unsatisfactory proposals, which failed to fulfil the requirements, greater success has been obtained during the last few years, and dry batteries which give general satisfaction are now coming into extensive use. It is evident that in cases where the liquids are subject to rapid evaporation, or where it is desirable to employ elements which, after their installation, require no further attention, and also in cases where portability is a condition to be fulfilled, dry elements will undoubtedly find their special field.

On the suggestion of Prof. Lommel, of the physical laboratory of the University of Munich, a series of experiments were conducted in November, 1889, by Mr. Heinrich Krehbiel, Dr. Narr, and Dr. Donle, in order to obtain an exhaustive comparison of the electrical qualities of six of the principal dry elements in existence—viz., those of Hellesen, Bender, Thor, Gassner, Jenisch, and Wolfschmidt.

A full report of these interesting experiments was published on August 1, 1890, in No. 31, Vol. II., of the *Elektrotechnische Zeitschrift*, of Berlin, containing a detailed account of the following investigations :

1. Change of the E.M.F. of the element on open circuit.
2. Variation of E.M.F. with temperature.
3. Determination of internal resistance.
4. Fall of E.M.F. on a closed circuit, and subsequent recovery on open circuit under the following conditions: (*a*) With an external resistance of three ohms, furnishing a strong current. (*b*) With an external resistance of 50 ohms, furnishing a weak current.

As the complete report of the Munich University is a very lengthy document, we only extract from it the principal data referring to that element which proved the most satisfactory—viz., Hellesen's—and quote only such results with regard to the other elements as enable their respective efficiencies to be directly compared with that of Hellesen's cell.

The E.M.F. was measured by an Edelmann's cylinder quadrant electrometer, by comparison with a Latimer Clark standard cell of 1·407 V (the coefficient for reducing the E.M.F. to the standard temperature being taken as 0·08 per degree centigrade, as given by Helmholtz and Kittler).

The measurement of resistances was effected by Kohlrausch's method, using alternate currents with the telephone introduced into the bridge. The Hellesen cells had the following dimensions : 8 cm. square by 16 cm. high (3¼in. square by 6½in. high).

The mean original E.M.F. in volts at 15deg. C., taken immediately after the receipt of the cells, was 1·415 V.

The E.M.F. of each cell was tested periodically during 2½ months, and remained, with slight variations, practically constant, no current, however, being taken from the cells during the time.

The E.M.F. was at 0deg. = 1·405 V, at 15deg. = 1·404 V, and at 30deg. = 1·404 V. Showing that the E.M.F. was practically unaffected by change of temperature.

The mean original internal resistance, taken immediately after the receipt of the cells, was 0·067 ohm; this resistance being lower than that of any of the other cells submitted for testing.

After these tests, one element of each kind was continuously closed for 36 hours through an external resistance of three ohms and

periodically tested; the result obtained with Hellesen's cell being the following:

At the beginning	0·066 ohm.
After ½ hour	0·071 ,,
,, 1 ,,	0·074 ,,
,, 4 hours	0·087 ,,
,, 8 ,,	0·096 ,,
,, 12 ,,	0·105 ,,
,, 36 ,,	0·172 ,,

The experiments proved that all the elements increased somewhat in resistance, when short-circuited in this way for a long time.

The next and most important trials refer to the recuperative power possessed by these cells. For that purpose they were closed for 60 minutes through an external resistance of 50 ohms, after which time the circuit was opened and the amount of recovery observed at intervals. This closing and opening of the circuit was repeated 25 times, the circuit of each element being closed for 60 minutes at a time, and the elements then left on open circuit for 24 hours, thus imitating in some degree the demands required in actual work.

The following table shows the decrease of the E.M.F. during the 60 minutes of closed circuit, and the recovery durirg the 24 hours of open circuit, given by the first of these 25 tests.

HELLESEN'S ELEMENT.

Closed.			Opened.		
Time of closing.	V.	Per cent.	Time of opening.	V.	Per cent.
0 minute.	1·420	100	2 minutes.	1·394	98·2
2 minutes.	1·405	98·9	5 ,,	1·397	—
5 ,,	1·402	—	10 ,,	1·397	—
10 ,,	1·399	—	20 ,,	1·398	—
20 ,,	1·398	—	30 ,,	1·399	—
30 ,,	1·397	—	60 ,,	1·402	—
60 ,,	1·391	98·8	24 hours.	1·411	99·4

All the elements, after 24 hours of open circuit, regained very nearly their original E.M.F.

The E.M.F. before the twenty-fifth test and its value as compared with the first test, was as follows:

Volts 1·369=96·4 per cent.

A far more crucial test was then made by closing each element continuously for 96 hours through an external resistance of 50 ohms, after which time the circuit was opened for 24 hours, and the amount of recovery observed. The results are contained in Table A.

According to this table the Hellesen element suffered the least loss in E.M.F. after 96 hours' work on closed circuit, retaining 1·207 V, or 87·5 per cent. of its original value; but the table also shows that the Hellesen element possessed the greatest recuperative power, attaining after 24 hours' rest 1·297 V, or 94·1 per cent. of the original value before the 96 hours of closed circuit.

After these experiments were brought to a close, a final test was taken by closing the cells for 60 minutes through an external resistance of 50 ohms, and then leaving them open for 24 hours. The following table gives the E.M.F. in volts during this test:

	Time.	Hellesen	Bender.	Thor.	Gassner.	Jenisch.	Wolfschmidt.
Closed.	0 min.	1·361	1·359	1·312	1·284	1·243	0·476
	5 mins	1 343	1·332	1·265	1·205	1·017	0·343
	30 ,,	1·338	1·318	1·217	1·184	0·906	0·277
	60 ,,	1·321	1·309	1·189	1·170	0·865	0·267
Open.	24 hr's.	1·349	1·352	1·304	1·285	1·225	0·475

The Munich investigation contains also the calculation of the ampere-hours from the values of current observed, and thus of the amount of work done by each element.

Table B gives the ampere-hours of the first, ninth, seventeenth, and twenty-fifth period of 60 minutes, when the circuit was closed through an external resistance of 50 ohms.

Table B demonstrates the superiority of the Hellesen element, the value of the ampere-hours during the twenty-fifth period being actually 96·7 per cent. of that furnished during the first period of closed circuit. This superiority is still more clearly shown by the ampere-hours which were furnished by the crucial test of the 96 hours on closed circuit, and which are as follows:

Hellesen	2·3915	ampere-hours
Bender	2·3400	,,
Thor	2 1435	,,
Gassner	1·9374	,,
Jenisch	1·0347	,,
Wolfschmidt	0·5967	,,

The ampere-hours resulting from the final test, and the percentage in value compared with that of the very first period of closed circuit, are given below, and here also the superiority of the Hellesen element is maintained; the elements having been on closed circuit for more than five days, four days being continuous.

Hellesen	0·0267	ampere-hours	95·6	per cent.
Bender	0·0262	,,	92·1	,,
Thor	0·0242	,,	86·4	,,
Gassner	0·0237	,,	83·2	,,
Jenisch	0·0183	,,	99·8	,,
Wolfschmidt	0·0058	,,	22·4	,,

In the foregoing experiments the circuit was closed through an external resistance of 50 ohms, but similar experiments were at the same time carried out through an external resistance of only three ohms. In these latter experiments the time of closed circuit was, however, only 30 minutes instead of 60 minutes; the number of periods being as before, 25 respectively, at intervals of 24 hours each.

The results obtained with Hellesen's cells after the first period of 30 minutes' work and 24 hours' rest are given in the following table, and it appears that the Hellesen element suffers the least polarisation.

Time of closing.	Hellesen.		Time of opening.	Hellesen.	
	V.	Per cent.		V.	Per cent.
0 minute	1·410	100	2 minutes	1·288	91·3
2 minutes	1·343	95·2	5 ,,	1·295	—
5 ,,	1·325	—	10 ,,	1·303	—
10 ,,	1·305	—	15 ,,	1·314	—
15 ,,	1·299	—	20 ,,	1·317	—
20 ,,	1·274	—	30 ,,	1·323	—
30 ,,	1·261	89·2	60 ,,	1·332	—
			24 hours	1·385	98·2

The following table shows a similar but more severe test than that of the preceding table, the elements having been close-circuited during 24 hours through an external resistance of three ohms and then given 24 hours' rest.

Time of closing.	Hellesen.		Time of opening.	Hellesen.	
	V.	Percent.		V.	Per cent.
0 hours	1·298	100	5 minutes	0·605	—
1 hour	1·007	77·6	60 minutes	0·776	—
4 hours	0·853	—	24 hours	1·084	835
24 hours	0·344	26·0	—	—	—

Table C gives the values of ampere-hours at the first, ninth, seventeenth, and twenty-fifth period when closed through an external resistance of three ohms. The duration of each period being 30 minutes.

The elements, when closed during 24 hours through an external resistance of three ohms, gave the following aggregate ampere-hours:

Hellesen	5·0792	ampere-hours.
Bender	4·9898	,,
Thor	3·4552	,,
Gassner	2·6670	,,
Jenisch	1·2236	,,
Wolfschmidt	1·6168	,,

This investigation of the comparative efficiency of the above elements was concluded by the experiment of regenerating the partially exhausted cells by a treatment similar to that of a secondary battery—*i.e.*, by sending a current from two Bunsen elements during two hours through the cells. The elements thus regenerated were again worked for five periods of closed circuit (each period of 30 minutes' duration) through an external resistance of three ohms.

The following table shows the E.M.F. of the partially exhausted Hellesen's cell before and after its regeneration by the two Bunsen elements, and also the E.M.F. of the last period of closed circuit, with the recovery after being on open circuit for 24 hours.

E.M.F. IN VOLTS.

		Hellesen.
Before	Regeneration.	1·225
Immediately after		1·994
24 hours after		1·580
Closed through three ohms.		
0 minutes		1·352
5 ,,		1·096
20 ,,		1·008
30 ,,		0·979
Opened.		
24 hours		1·309

The ampere-hours calculated from the results of this last test after the regeneration, and the percentage of the value of the last period before regeneration, were found to be as follows:

Hellesen	0·1656 ampere-hours	= 172·9 per cent.
Bender	0·1384 ,, ,,	= 114·3 ,,
Thor	0·1005 ,, ,,	= 148·9 ,,
Gassner	0·1590 ,, ,,	= 151·0 ,,
Wolfschmidt	0·0556 ,, ,,	= 134·9 ,,

The Munich report contains the following conclusion as the results of this exhaustive and carefully conducted series of experiments:

"The most efficient elements, even for circuits of a small external resistance, are Hellesen's and Bender's elements. Hellesen's element excels Bender's by having somewhat less polarisation and much smaller internal resistance; it has, however, when exhausted by long working, not quite so much recuperative power as Bender's.

"A similar relationship exists between Thor's and Gassner's element. In a circuit with a small external resistance, Gassner's is less constant than Thor's, but the former has the advantage of more recuperative power, even after the E.M.F. has been reduced to a very small value.

"Jenisch's and Wolfschmidt's elements are, in consequence of their very rapid polarisation, unsuitable for giving even approximately constant currents; hence they are only applicable when duration of closed circuit is very short.

The above experiments prove that dry elements are well adapted for many practical purposes, especially for telegraphic, telephonic, and similar services, and the considerable power of recovery possessed by such elements gives them a long duration of life.

Hellesen's elements being able to produce strong currents during a long period are well adapted to supersede the cells of Leclanché, Meidinger, and similar types, and in many cases even those of the Daniell types.

Besides the electrical advantages shown in the tables accompanying the Munich report, there are various other advantages of a purely practical character possessed by such cells when compared with wet elements. The former are transported with far more facility, being always, and without any previous preparation, ready for use, and require no inspection or attention until they are completely exhausted.

Messrs. Siemens Bros. and Co., 12, Queen Anne's-gate, Westminster, London, are the sole manufacturers in England of Hellesen's patent elements.

LEGAL INTELLIGENCE.

COOPER v. GREAT WESTERN RAILWAY.

Electric Lamps Damaged in Transit.

In the Westminster County Court on the 29th ult., the case of Cooper *v.* the Great Western Railway was before his Honour Judge Bayley, and was an action by the plaintiff to recover the value of two electric lamps which he alleged had been smashed while in the care of the defendant company for the purpose of transit from London to Swansea.

The **Plaintiff** (Mr. Cooper) was called, and said that in July last year he forwarded the lamps in question to a customer at Swansea. The box containing them was entrusted to the defendants to forward on to Swansea. Shortly afterwards he received a letter from his customer stating that the lamps were smashed and useless, and had been returned. A few days afterwards the box was returned per Midland Railway, and the contents were found to be broken up. The defendant company were then communicated with as to compensation for the damage, but as they refused to recognise his claim the damaged articles were returned to them, and the present action was brought to recover some recompense for the damage done.

John Frost, a servant in the plaintiff's employ, said he personally superintended the packing of the lamps. He made a box purposely for them in order that they should travel safely. He also lined the box with any quantity of paper, and it was impossible for the lamps to have been broken unless they had been very badly used.

The **Solicitor** for the defendant company submitted that he was entitled to judgment, as the plaintiff had totally failed to prove negligence on the part of the defendants. The plaintiff's own customer had written saying that the goods were improperly packed, and in the face of that letter he submitted that no liability could attach to the company. He (defendants' solicitor) thought the best thing the plaintiff could do would be to take back his lamps and say no more about the matter.

Without hearing any evidence for the defence, his **Honour** said the plaintiff had failed to make out his case, and therefore judgment would be for the defendants with costs.

SOMERTON v. LONDON ELECTRIC SUPPLY CORPORATION.

Claim for Damages.

In the Westminster County Court on the 28th ult., the case of Somerton v. The London Electric Supply Corporation was before his Honour Judge Bayley, and was an action by the plaintiff to recover damages against the defendant company for alleged wrongful dismissal from their service.

The **Plaintiff** (Mr. Edward Somerton) was called, and said he entered the service of the defendant company about May 22nd last year, as a shorthand writer at a salary of £90 per annum. The terms of the engagement were that a month's notice was to be given on either side. He had not been long in the employ of the defendants before he was discharged without any notice. He now claimed a month's wages in lieu of notice, and a further month for wrongful dismissal.

For the defence it was submitted that there was in existence a written agreement, and the plaintiff's case could not be sustained without it.

The **Solicitor** for the plaintiff said it was true there was a written agreement, but, unfortunately, it was not stamped, and therefore could not be put in as evidence.

His **Honour** said the agreement could not be put in as evidence unless stamped, and the plaintiff's case could not go on without it.

The defendant's **Solicitor** asked for judgment.

The learned **Judge** entered a non-suit, but refused to allow any costs.

COMPANIES' MEETINGS.

ELMORE'S FOREIGN AND COLONIAL COPPER COMPANY.

The second annual general meeting of this Company was held on Thursday week, Sir J. H. Morris, chairman, presiding.

Having explained why the Board agreed to take £50,000 of the French Elmore's Company's debentures, the **Chairman** referred to the profit and loss account. The amount received from the sale of the French and Hungarian patents was £257,750, from which £30,000 had been deducted to represent the original capital value of the patents sold, leaving a net amount, after adding items for interest and transfer fees, of £228,341. 19s. After allowing for sundry working expenses there was a balance carried down of £222,772. Out of this they had paid an interim dividend £4 per priority share, which absorbed £60,000. Under the articles the Directors were entitled to 5 per cent. of the net profits of the Company after paying 10 per cent. per annum upon the priority share capital—this amounted to £10,605. It was a large amount, but was fixed by the articles, and was for work done. They would take it in any way the shareholders might determine. The balance carried forward was £152,167. The total on the credit side of the balance-sheet was £319,192, which was balanced by share capital £120,000, and the sum due to sundry creditors £47,025. In a circular issued on November 13 last it was proposed to form a trust company to take up the securities held by the Company. There were three courses open to them: (1) to form an Elmore Trust Company; (2) to hold the shares themselves, realise the profits, and distribute them to the shareholders; (3) to alter the articles, and thus become empowered to distribute the shares and debentures to the shareholders as if they were cash. The Chairman then moved the adoption of the report and accounts, which was seconded by **Mr. John Macfarlan**, and carried.

The **Chairman** next moved: "That a dividend of 20 per cent., or £1 per share, less income tax, be paid on Feb. 4 upon the priority share capital, making, with the interim dividend of £4 per share paid on December 8 last, a total dividend of 100 per cent. for the nine months ending December 31 last."

Mr. Edward J. Carson seconded the resolution, which was agreed to.

The **Chairman** said it was the wish of the Directors to consult the interests of the shareholders in regard to the realisation of the Company's securities; therefore, he was quite ready either to call a special meeting to consider the question or to confer with a committee of shareholders.

After some discussion it was decided to leave the matter in the hands of the Board, with the view of calling a special meeting at a subsequent date.

The retiring Directors were re-elected, as were also the Auditors.

The following resolution, which was passed by a general meeting on December 29, was confirmed: "That once at least in every year the Board of Directors shall lay before the Company in general meeting a statement of the income and expenditure for the past year, made up to December 31 then last past, instead of to March 31, as provided in Clause 113 of the Company's articles of association."

A vote of thanks to the Chairman and Directors terminated the proceedings.

CITY AND SOUTH LONDON RAILWAY.

A special general meeting of the shareholders of this Company was held at the offices, King William-street, E.C., on Tuesday, to consider a Bill which has been deposited in Parliament, by which powers are sought to construct an extension of their line from the City to the Angel at Islington. The chairman, Mr. C. G. Mott, presided.

The **Secretary** having read the notice convening the meeting, and the **Solicitor** having given the gist of the chief clauses in the Bill, from which it appeared that the construction of the railway will be identical with that of the City-Stockwell line, and that the capital to be obtained is £660,000 in £10 shares, with borrowing powers up to £220,000,

The **Chairman** said that the meeting was called simply to consider whether they would proceed with the Bill which had been provisionally introduced into Parliament for the construction of an extension of this (the City and South London) line from King William-street to the Angel at Islington. It had never been the desire of the Directors of that Company to proceed with anything in connection with that line at all hastily. They had from time to time, as the shareholders knew, been asked to go for various extensions; but except the small one at the Clapham end, which they had obtained powers for last year, they had declined all such proposals up to the present. Their desire was rather to consolidate and work their railway satisfactorily before they proposed to extend it, and that had been the view the Directors had taken all along. Last year they declined this very line (the Islington) when proposed to them. The result was that they were threatened with another Bill—viz., the Central London—in which the promoters proposed to take and occupy the ground, which would have prevented the City and South London Railway from ever being extended into the City of London. Some of the best traffic for a railway of this kind was to be had ultimately from the busy portions of the City, and it did not appear desirable that their road should be permanently blocked so that they could never go for that traffic. On that account they thought it wise that notice should be given this session for a Bill such as that (which had been read) was to obtain for them the road into the City at any time they desired to go there. He thought this line could be carried out at a comparatively small expense per mile, and would go through one of the very busiest traffics they could well have in the City. It would go by the Bank, Moorgate-street, and the City-road, and so far as the Directors could judge it would pay quite as well as, perhaps better than, their existing line. He would rather that the matter had been postponed, but it did not appear to the Directors safe to do so at the present moment, and they thought they had better obtain the Act. As to the exact time of carrying it out, and the mode, whether as part of the capital of the existing line, or as a separate concern, these were matters which, if the Bill was obtained, the shareholders would have to decide for themselves at a later date. That was their position now. The Directers would have postponed any further action if they could have done so safely, but they thought that it was desirable in the shareholders' interests that the Bill should be obtained if possible, and that the line would be a good one. The great object of a line of that kind was this. Morning and evening there was a very large rush of traffic into and from the City, as much as their line could take, but during the middle of the day the trains were not full. This was the experience of all Metropolitan railways, more or less, and their great object in order to make a good dividend was, as far as possible, to fill up these midday trains. Now the effect of another line, such as the Islington extension, would be that they would largely improve the midday traffic on their existing line, and the latter would improve the midday traffic upon the former. Therefore, they would have a better chance of a dividend on their existing line, if a line such as the proposed one were working. It was on account of these facts that the Board were disposed to recommend that the Company should go on with this Bill. The immediate effect of their proceeding had been that they had prevented the Central London Company from occupying the ground. They had altered their Bill, but if they (the City and South London) withdrew theirs, they would leave the ground again unoccupied. As regarded the City-Stockwell railway, they had as yet only been working for six weeks. On a new line like that they had had a great many difficulties to contend with in the working of an undertaking which, as the shareholders knew, was practically unexampled in the history of railways in this country. A service such as they had started, and hoped to still further develop, had never been attempted on any railway. With the exception of small portions of the District Railway service, no complete railway had run trains at the same rate or number as this line was running, and he thought they had reason to be extremely satisfied on the whole with the working of their electrical line. They had seen many paragraphs in the papers complaining of breakdowns. They were, unfortunately, very strongly before the public at the moment, and notice was taken of everything on that line in a way which was not the case with other railways. They had run up to the present time about 11,000 trains. During that period they had had with their engines, which had been the chief causes of delay, 18 failures in running. He did not think they would say that was a large number out of 11,000 trains run. The number of trains working on their line was very large, and it was quite impossible that such a large number should be run without some accidents occasionally. That there should have been only 18 failures of engines out of 11,000 runs was altogether creditable to the electrical system. They were doing their best to reduce that number, and get rid of failures, if possible, altogether; that they should be able to do so did not seem very likely, looking at the history of human inventions. But they would so minimise the delays when they occurred that the public would feel no inconvenience. The result of the above-mentioned paragraphs had been that many people who would have travelled with them had supposed that the line was stopped and did not go, and the traffic had been damaged. He was satisfied from what he saw now, however, that they had a steadily-improving traffic and a satisfactory result from it. The expenses of working so far as electricity was concerned had turned out satisfactorily, and were quite equal to what they expected so far as economy went. On the whole the prospects of the line were by no means bad. As regarded the new Bill, the Directors were quite in the shareholders' hands in the matter, but he thought they would be wise to let the Bill go on, obtain the powers, and deal with the question of using them as they might think fit later on. He moved that the Bill, which had been read to the meeting, be approved.

This was seconded by **Mr. Hubbard.**

In answer to a shareholder, the **Chairman** said that five years was the usual period given in a Bill for constructing the works, and if they did not want to do them in that time, the plan was to go to Parliament for an extension.

Mr. Broad objected to the expense being incurred in getting this Bill.

The **Chairman** said they did not want to proceed with the Bill if the shareholders did not like it. They had gone in for it themselves rather reluctantly, as a protection to the shareholders. If they thought it better to run the risk of withdrawing the Bill, because it was a very considerable risk, it was for them to say so. The Directors had given them an opportunity of discussing the question, and it was for them to decide.

Mr. Broad moved that the Bill be withdrawn.

In answer to a question as to who would have to pay the expense of getting the Bill, the **Chairman** said the shareholders of the existing line; that it was not an expensive Bill to get through, and might cost £1,500.

A **Shareholder** thought that the present line should be completed and proved and tested in every possible way, and when they had made it pay, extend if they liked; or if other people were going in they could take shares in their Company. He thought the Bill should be withdrawn.

Another **Shareholder**, who represented £75,000 of stock in the Company, said that he had not heard yet, but thought from the deposited plans that he saw that the proposed junction between the new line and the existing line was not, in fact, a junction at all. The proposed method was to have a foot subway between the two, and it was not, therefore, a physical junction between the two railways. If that was so, what the Chairman had said about occupying the ground would hardly be the case, because unless they had a physical junction it would still be open to any other Company to ask for a physical junction with the rails of that line and power to enter into its terminus. He had not seen these plans until then, and would like to have an opportunity of considering the matter. The shareholders knew little or nothing about the proposal, and had no opportunity of considering it, and although the notice given to the shareholders was in accordance with the Act of Parliament, it contained no information, and, under the circumstances, he thought it would be well to adjourn that meeting for a week to give them an opportunity of looking into the matter.

The **Solicitor** having explained that the meeting could be adjourned if they liked,

The **Chairman** said they could adjourn to the general meeting on the 24th inst.

The **Shareholder** who had last spoken then moved the adjournment of the meeting to the ordinary general meeting on the 24th inst. His own opinion was that if the objections could be got rid of, the scheme would be an addition to the Company. Besides, by the date above mentioned, they would know more about the working of their own line.

Mr. Broad saw little use in adjourning.

Mr. W. A. Smith seconded the adjournment.

A question having been asked as to the capital of the new line, the **Chairman** explained that it was larger than for the existing, £660,000 as against £600,000, because in going through the City it might be necessary to pay a large sum for station sites, and they were obliged to have sufficient capital in the Bill to cover this cost.

A **Shareholder** asked whether a physical junction between the existing and proposed lines was possible, and

Mr. Greathead, engineer to the line, said it was.

The adjournment of the meeting was then put from the chair, and carried.

A desultory conversation then ensued, during which the **Chairman** said, with reference to a question as to why the City and South London line was not worked on Sundays, that they must have patience. The staff were employed night and day, Sunday and every day. They had to feel their way, and the delays and difficulties were all capable of remedy and being remedied; but they could not do everything in six weeks. He thought they would be perfectly satisfied by-and-by, as no stone was being left unturned to make the line a success. There were no trains running on Sunday, but the time was not far distant when they would be.

A hearty vote ot thanks was accorded to the Chairman, on the motion of **Mr. W. A. Smith.**

PROVISIONAL PATENTS, 1891.

JANUARY 26.

1390. **An improved incandescent electric lamp.** Ernest Boehm, 42, Little Britain, London.

1396. **Improvements in arc lamps.** Francis Murray Newton, 46, Lincoln's-inn-fields, London.

1425. **Improvements in storage batteries.** Alfred Julius Boult, 323, High Holborn, London. (William Roberts, Canada.) (Complete specification.)

JANUARY 27.

1432. **Improved manufacture of carbon filaments for incandescent electric lamps.** Carl Bollé, New Bridge-street, Manchester. (William M. B. Keen, United States.)

JANUARY 28.

1527. **Improvements in and connected with apparatus for receiving electrical signals.** Thomas Alexander Garrett, 128, Clerkenwell-road, London.

1528. **Improvements in the method of cooling magic lanterns, resistance and other optical or electrical apparatus liable to get overheated.** Charles Walter Cox, 6, Lord-street, Liverpool.

JANUARY 29.

1599. **Improvements in apparatus for stopping any waterwheel or other motor used in generating electricity.** William Scott Elliot, 154, St. Vincent-street, Glasgow.

1639. **Improvements in or connected with distribution of power by alternating currents with the aid of condensers, alternate-current motors, fuses, and electrostatic measuring instruments, and improvements in telephone systems.** James Swinburne, Broom Hall Works, Teddington.

1672. **Improvements in laying or running wires for electric lighting.** William Turner Lord, Stamford Brook Villa, Hammersmith, London.

1680. **A new or improved process for the manufacture of wire for transmitting electric currents.** Alphonse Edouard Tavernier, 4, South-street, Finsbury, London.

JANUARY 30.

1741. **Improvements in electric welding, and in apparatus therefor.** Henry Howard, 24, Southampton-buildings, London.

JANUARY 31.

1779. **Improvements in motors and dynamos for use in mines and other places.** Wilson Hartnell, Volt Works, Leeds.

1788. **Improvements in the construction of battery elements.** Mark Bailey, 21, Finsbury-pavement, London.

1804. **An improved arrangement of shunt for electric motors.** George Frederick Redfern, 4, South-street, Finsbury, London. (Wirth and Co., agents for W. Lahmeyer and Co., Germany.)

1818. **A new or improved preparation of soluble bichromates and sulphuric acid for use in charging voltaic batteries and for other purposes.** John Benz Winder, 7, Staple-inn, London.

SPECIFICATIONS PUBLISHED.

1890.

836. **Long telephonic circuits.** Gwosdeff and Bunge. 8d.

873. **Electric supply meters.** Perry. 8d.

1306. **Galvanic dry elements.** Smith (Hellesen). 6d.

2091. **Secondary batteries.** Thompson (The Gibson Electric Company). 8d.

2653. **Electric meters.** De Ferranti. 8d.

2759. **Lighting railway trains by electricity.** Timmis. 8d.

3841. **Electric conductors.** Siemens Bros. and Co. (Taylor). 6d.

3842. **Electric circuit breakers.** Siemens Bros. and Co. (Taylor). 6d.

13319. **Electric bells, etc.** Townley. 8d.

15547. **Electric current circuits.** Iliffe and Teaque. 8d.

16064. **Electrical batteries.** Pumpelly and Butterworth. 6d.

16653. **Measuring the strength of electric currents.** Currie. 6d.

17181. **Electric switches.** Allison (McGregor and others). 8d.

18412. **Electric batteries and lighters.** Robertson. 6d.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The receipts for the week ended January 30 amounted to £6,215.

City and South London Railway.—The receipts of this Company for the week ended January 31 amounted to £704.

Direct Spanish Telegraph Company.—For the month of January the receipts show a decrease of £268 as compared with the corresponding period.

West India and Panama Telegraph Company.—The receipts for the half-month ended January 31 show an increase of £425 as compared with the corresponding period.

Venezuela Telephone Company.—The coupons on the debentures of this Company, now due, are payable on presentation at the Consolidated Bank, Limited, 52, Threadneedle-street, E.C.

Woodhouse and Rawson United.—The Directors have declared an interim dividend at the rate of 15 per cent. on the ordinary shares, and 8 per cent. on the preference shares, in respect of the profits to December 30 last.

Western and Brazilian Telegraph Company.—The receipts for the week ended January 30, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £4,996.

Cuba Submarine Telegraph Company.—The Directors, after providing for the dividend on the preference shares and placing £4,450 to the reserve fund, recommend a dividend on the ordinary shares at the rate of 8 per cent. per annum, tax free, carrying forward £715.

Smith's Patents, Limited.—Registered by Newman, Hays, and Co., 31, Abchurch-lane, E.C., with a capital of £5,000 in £1 shares. Object: to carry on the business of indiarubber manufacturers and merchants in Great Britain and elsewhere, in accordance with an agreement made January 22 between J. S. Smith of the one part and John Cunningham, on behalf of the Company, of the other part. Registered without articles of association.

NOTES.

Berlin Tramways.—The Allgemeine Gesellschaft of Berlin is erecting an electric tramway about six miles long at Gera.

Cavendish Laboratory.—Mr. R. T. Glazebrook, of Trinity College, has been appointed assistant director of the Cavendish Laboratory.

Ship Lighting.—The "Ottawa," a new screw steamer built by Messrs. Stephen and Sons, Glasgow, is luxuriously fitted throughout with electric light.

Matlock Bath.—There is a proposal to light Matlock by means of power from the river, and the engineer of the Local Board will shortly submit a report.

New Peru and Chili Cable.—The "Silvertown" has been reported from Arica, all well. She completed the cables between Chorillos, Yquique, and Valparaiso on February 2.

Cambridge Appointments.—Mr. G. F. C. Searle, M.A., of Peterhouse, and Mr. S. Skinner, M.A., of Christ's College, have been appointed demonstrators of experimental physics.

Duke of Westminster and the Electric Railway. In the House of Commons a petition has been presented against the Central London Railway Bill by the Duke of Westminster.

British Association.—At a conference of foreign consuls in Cardiff this week it was agreed to take steps for inviting distinguished foreign scientists to the meeting of the British Association.

Training Cannons by Motors.—Electric motors are being applied in France, at the La Seyne works, to train heavy cannons for armour-plated vessels, the dynamo supplying current being placed below the bridge.

Leeds.—The Electric Light Committee of the Leeds County Council have again discussed the question of electric lighting at considerable length, and requested Mr. Hewson, the borough engineer, to obtain further information.

St. Martin's Free Library, opened yesterday by Mr. Gladstone, is lighted by electric light. The Metropolitan Supply have undertaken to supply current until the London Electric, in whose district it is, are in a position to do so.

Oxford.—Before the Oxford City Council, an application was made by the Electric Installation and Maintenance Company, Limited, for an extension of time under section 7 of the Oxford electric lighting order, and it was granted.

The St. James's Theatre, whither Mr. Geo. Alexander has betaken himself, *vice* the Avenue, was opened by its new manager last week. It has been magnificently upholstered by Messrs. Oetzmann, of Hampstead-road, and is lighted electrically.

Substitute for Guttapercha.—Senhor da Costa, a Portuguese scientist, is reported from Goa to have discovered an excellent substitute for guttapercha in the solidified sap of the nivol-cantem, which grows wild in hedges in the Cencan district.

Patent Office.—Mr. Goschen, in answer to a question with reference to the surplus of £93,534 at the Patent Office, stated that this surplus, or a large part, would be applied to providing additional accommodation and not to reducing fees to patentees.

Tamworth.—At the meeting of the Tamworth United District Water Works Committee, the tender of Mr. H. Hicklin was accepted for laying telephonic communication between the offices of the committee and the pumping station at Hopwas, the price being £43. 10s.

Charterhouse School, though removed to Godalming, must still be considered as part of London, and is intending to do as London is now doing, introduce the electric light. The head master, we learn, is making determined endeavours to have the new illuminant introduced at once.

Grimsby.—There is talk at Scunthorpe, New Grimsby, about the electric light. The Local Board approached Lord St. Oswald about leasing some land that the gas works stand on, and were advised by him to have the electric light. The proposition is by no means badly received.

Hastings.—At its annual meeting, the Hastings Electric Light Company declared a dividend at the rate of 5 per cent. for the last nine months. The company are negotiating for the electric lighting of St. Leonard's Pier. A report of the meeting is unavoidably held over.

Electric Welding.—Two Belgian civil engineers, M. Lagrange and M. Paul Hoho, have perfected a system of electric welding differing essentially, it is stated, from that of Elihu Thomson. The process will be exploited in Belgium by the Julien Electric Company, of Brussels.

Electricians' Exhibition.—A third annual exhibition of engineers, electricians, builders, and ironmongers will be held in the Royal Agricultural Hall from April 23 to May 2, under the management of Mr. H. Hetherington, 42, New Oxford-street. Applications for space can now be received.

Hull.—Messrs. Baily and Grundy, of Paddington, have just completed the lighting of Messrs. Pearson and Bailey's large seed-crushing mills. The installation comprises about 200 16-c.p. lamps. The work was carried out under the direction of Mr. J. E. Tongue, manager for Messrs. Baily and Grundy.

Newcastle Telegraphs.—For the working of the Newcastle telegraph wires 3,890 battery cells are used, and it will interest electricians to notice the rate at which the Fuller battery is displacing the Daniell. There are in use at the Newcastle Post Office 2,420 Fuller cells, 1,270 Daniells, and 200 Leclanchés.

Fire Alarms for Coventry.—The Fire Brigade Committee of the Coventry City Council have requested the city surveyor to ascertain the cost of laying and maintaining communication, by means of electric bells, between the police station and the residences of the members of the fire brigade, for summoning them in case of an alarm of fire.

Portsmouth.—At a meeting of the Electric Lighting Committee last Friday morning, it was decided to recommend the Town Council to take the management of the electric lighting works in the borough instead of leasing the powers granted the Corporation to a private company. The Council is asked to adopt the low-tension system, whereby the danger of overhead wires is avoided.

Liverpool. — The Liverpool Electric Light Company wish to obtain power to extend their supply over a much larger area in the city than their present powers enable them to do. On making their application to the Lighting Sub-Committee, after explanations and considerable discussion, it was decided to decline to accede to the extension on the terms submitted by the company.

Manchester.—On the presentation of the minutes of the Manchester Gas Committee for approval, Mr. J. Brooks said he thought it was desirable to inform the Council that the Electric Lighting Committee were actively engaged investigating the best mode of supplying that light to the public. A report would shortly be presented to the Council as to the manner in which it was best to be done.

German Exhibition.—The Gulcher (New) Electric Light Company, of Battersea, we hear, have obtained the whole of the electric lighting of the German Exhibition this year to be held at Earl's Court. This will make the third year that the same company has lighted up the same buildings and grounds, and if this year is as great a success as the past two years it does the company great credit.

A Runaway Engine.—An awkward accident occurred at Lynn, Mass., which ought to have been avoided by the use of a proper governor. An electric station caught fire and the wires carrying current were burnt. Relieved of the work, the 700-h.p. engine started off, became unmanageable, and the flywheel was broken and scattered in all directions by centrifugal force, with much damage to the building.

Commissioners of Sewers.—In view of the imminent lighting of the City by the Commissioners of Sewers, the chairmanship of that body for the current year has been an object of keen competition. The contest was this week fought by three gentlemen, under the presidency of the Lord Mayor himself. Eventually Mr. Deputy Sheppard Scott headed the poll, and was declared to be duly elected.

Telephone on Shipboard.—Most of the French navy have been fitted with special telephone sets by the Société Générale des Téléphones, the parts being constructed so as not to be damaged by damp, even if dipped in sea-water for several hours. The line has five wires with a distinct circuit for the bell. Experiments on board the "Devastation" show that speaking is distinct even when firing big guns.

Telephone at Newcastle.—The Post Office exchange at Newcastle now has about 600 subscribers, and in anticipation of a large increase when the existing patents run out in July, the department is introducing the latest and most costly form of multiple switchboard, whereby inter-communication will be greatly facilitated for 1,000 subscribers. The National Telephone Company have one for 5,000 connections.

South Kensington and Paddington Subway.—A specially convened meeting of the Paddington Vestry has, by two to one, decided not to oppose the scheme for the construction of an electric railway from South Kensington to Bishop's-road, Paddington, provided the promoters give an undertaking to insert in their Bill protective clauses as regards the sewers and other matters which are under the jurisdiction of the Vestry.

Ipswich Asylum.—Tenders are invited for providing and fixing the engine and all necessary plant and appliances for lighting the Borough Asylum by electricity. The premises are about two miles from Ipswich railway station, and can be viewed and further particulars obtained on application to the medical superintendent at the asylum. Tenders, endorsed "Tender for Electric Lighting," to be sent to the chairman of the committee, at the asylum, before March 4.

Eastbourne.—At the Eastbourne Town Council, a letter from the Board of Trade, with a copy of the system proposed to be adopted by the electric light company under the provisional order, was read, and the borough surveyor reported thereon, stating that the system proposed was satisfactory, subject to the iron pipes containing the mains being provided with a sufficient number of service boxes. It was resolved that the report be adopted and forwarded to the Board of Trade.

Cantor Lectures.—The first of the set of Cantor lectures on "The Electric Transmission of Power," by Gisbert Kapp, will be given on Monday, February 16, at 8 p.m. Syllabus of Lecture I.: Importance of Transmission generally; Distinction between Live Power and Stored Power; Stored Power transmitted by Electricity and Air under Pressure; Comparison between Various Ways of transmitting Stored Power; Cost of transmitting by Battery and Electromotor; Application to Tramcars.

Dover.—At the meeting of the Dover Town Council, the town clerk reported that he had, by the request of the Finance Committee, written to the Local Government Board, asking if they could defer the loan for the preliminary expenses connected with the electric light until the loan for the works was asked for, and their reply was that it must not go beyond the financial year. It was ordered, therefore, that application should be at once made for permission to borrow £550 for the preliminary expenses.

Leamington.—A special meeting of the Corporation was held on Tuesday, for the purpose of taking steps to apply for a provisional order for the supply of the electric light for public and private purposes. Mr. J. Hinks, mayor, presided. The Council decided to apply under the Electric Lighting Act for a provisional order, and that the consent of the Corporation be not given to the application of the Midland Electric Lighting Company for a provisional order, but that the town clerk be instructed strenuously to oppose such application.

Oil Engine.—A new petroleum motor is described in this week's *Electricité*, designed by M. Daimler, and made by MM. Panhard et Levassor, of Paris. The sizes now made are from ½ h.p. (700 revolutions) up to 5 h.p. (550 revolutions), the latter type being with four cylinders. The fuel consumption is low, one pint of petroleum per horse-power hour. The larger type, 5 h.p., goes into small space, 2ft. 6in. by 1ft. 9in., and 3ft. high. It is well made, and has been applied with much success to driving dynamos for small private installations.

Bradford.—At the meeting of the Leeds Gas Committee Alderman F. Priestman, in referring to electric supply, said he thought the Corporation had taken the proper course in having an installation of electricity, instead of allowing private companies to get the power to compete with the gas works and eventually render it necessary for the Corporation to buy them out. It was unkind of Leeds aldermen to point to the action of Bradford as an instance of failure, for quite recently deputations from other towns had visited Bradford and expressed gratification with what they had seen.

Accrington.—At the Accrington Town Council the town clerk read a letter from the Accrington and Church Co-operative Society urging the Corporation to take into consideration the early introduction of electric lighting into the borough. It was resolved that the town clerk write to the society and ask them if they were prepared to take a supply of electricity for lighting up all their shops and premises within the borough at such price, not exceeding the maximum allowed by the provisional order, as the Corporation may supply it at after the establishment of their works.

The Trans-Pacific Cable.—The Hon. Audley Coates, a member of the Legislative Council of Sydney, writes to Sir John Macdonald, the Candian Premier, in reference to the Trans-Pacific cable, proposing a conference of Canadian and Australian delegates, to be held in May next. Mr. Coates says that three Governments will guarantee to share any loss that may occur, and that Hawaii and Fiji will each give £5,000 a year for 15 years. The projected route of the cable is from Vancouver to Hawaii, Samoa, Fiji, and Queensland. The cost is estimated at £2,000,000, and the guarantee is expected to extend to about £750,000 per annum.

Guernsey.—The Guernsey Railway Company, Limited, having obtained the necessary authority for the use of electricity as a motive power on the parallel system by means of an overhead conductor, the directors are prepared to consider proposals from firms willing to carry out the required alterations, including the supply of the electrical plant. The line may be inspected by appointment with Mr. William Gumbley, secretary and manager, 35, High-street, Guernsey, from whom any further information may be obtained, and to whom proposals should be addressed so as to reach him by 28th inst.

Utilising Tidal Power.—At the last meeting of the Yorkshire College Engineering Society, a discussion took place on "The Utilisation of Tidal Power." The subject was started by Mr. W. H. Drake, and Prof. Goodman took part in the discussion. The resultant opinion was that the power available from this source has been considerably over-estimated. The greatest possible advantage derivable from each acre of water 10ft. deep, reckoning a working day at eight hours, was stated to be 3¾ h.p. It was considered of more importance to economise the present wasteful consumption of coal by improved appliances and greater care.

Gatling Guns Fitted with Motors.—The Ordnance Bureau of the U.S. Navy Department has made a series of exhaustive trials at the Annapolis proving ground of the method of firing Gatling guns by electricity. The electrical apparatus substitutes for the man at the crank a small Crocker-Wheeler motor, by which the gun is fired at any desired speed up to 1,200 shots per minute, requiring only one man to direct the fire. The motor is attached to the breech of the gun and can be instantly detached if injured by a shot, and the crank can be used. As a result of these trials it has been decided to have the motors fitted to all Gatling guns on shipboard.

London County Council.—The sanction of the London County Council has been given to the works of the Notting Hill Electric Lighting Company, subject to conditions that the stone cover to the culvert shall be 2in. thick, and when crossing the roadway that 9in. of cement concrete shall be laid in addition. Also of the Westminster Electric Supply Corporation, with the conditions that the mains shall be laid under the footpath where practicable, and the boxes shall be of iron filled in with paving material. Also with reference to the Electricity Supply Corporation (Gatti), that four days' notice of intended service from distributing mains be sufficient instead of one month as heretofore.

Bath.—The Electric Lighting Committee of Bath having engaged Prof. Forbes, at a fee of fifty guineas, to make a thorough inspection and report for the Town Council upon the works at Bath, a meeting was arranged last week at the city surveyor's offices. At the same time, Mr. Massingham is having a most minute investigation made by Major-General Webber, R.E., who commenced his inspection about three weeks ago, but was unable to continue it owing to other engagements. This survey has been resumed this week. General Webber is thoroughly testing all the machinery to see that it is according to specification, and makes a separate inspection of each boiler, engine, dynamo, and circuit.

Electricity for Agriculture.—M. Camille Gonzy, the proprietor of numerous small farms in the commune of Millas (Western Pyrenees), having an area altogether of nearly 1,500 acres, has for some time past been utilising a neighbouring stream for electric lighting purposes. He has now applied electric power to the working of a wine-crushing plant. Besides providing the power for lifting and driving purposes, electricity is made to work the pumps for irrigating the vines. The 180 16-c.p. lamps employed are distributed over all the farms, and the area which they cover may be judged from the fact that the length of telephone wire connecting the buildings is 62 miles.

Coventry.—A special meeting of the City Council was held on Tuesday afternoon, when Alderman Tomson (deputy mayor), who presided, moved that application be made to the Board of Trade for a provisional order under the Electric Lighting Acts, authorising the Corporation to erect and maintain electric lines and works, and produce, store, supply, and distribute electricity for public and private purposes within the city. Mr. Andrews (chairman of the Gas Committee) seconded the resolution, and Mr Loudon, in supporting it, said that up to the present it was the experience of other towns where electric lighting had been adopted, that there was no perceptible falling off in the consumption of gas. The resolution was adopted.

French Telephones.—Before the Glasgow Philosophical Society last week, Mr. A. Erskine Muirhead exhibited and described the latest form of French telephones, including such as are specially adapted for railway signal cabins, steamers, and mines, or for military or other temporary purposes. The demonstrator explained that though the French telephones were new to the public of this country, they had been before the telephone experts of Europe for a decade. Mr. Muirhead alluded to the exchange system, and specially dwelt upon the defects in the present connecting and disconnecting system, which required great improvement. He concluded with an allusion to the batteries in use, and exhibited a new dry cell, made in Paris, and handy for steamers or railway carriages.

Ferranti Mains.—The workmen have been busy for the last few weeks along the railway line from Charing Cross to Deptford in completing the four sets of Ferranti mains, of which two only had been previously finished. For some time past, during the alterations and installation of the sub-distributing stations, current has been transmitted at full pressure of 10,000 volts from Deptford to London and back, the load being taken off again at Deptford. Not a single fault resulting from the high pressure has yet been found, though difficulty was met with in the first laying, to find a fault of blank want of continuity in the underground main—a problem it will be felt by electricians, on a little reflection, to be a very peculiar one, when combined with absolutely good insulation, to readily find out by any ordinary means of testing.

High Tension for Frankfort.—The Oerlikon Company have recently carried out some experiments with reference to their proposed intention of transmitting 300 h.p. to the Frankfort Exhibition from Lauffen-on-Neckar, a distance of over 100 miles, in conjunction with the Allgemeine Gesellschaft of Berlin. The experiments were carried out over a line a mile long with pressure increased gradually, commencing at 1,500 volts and rising to 33,000 volts. Transformers were inserted at one end of the line to transform upwards and other transformers at the further end to retransform downward. The result of these experiments, when they have had accorded to them such a practical shape as that proposed, if consistently successful, could not but prove extremely important as the starting point of many attempts of transmission of power at these enormous voltages.

New Book.—We have received a copy of "An Explanation of the Phonopore, and the Simplex Phonopore Telegraph," by C. Langdon-Davies, with reports on the Phonopore system by Mr. Latimer Clark, Prof. Silvanus Thompson, Mr. Conrad Cooke, and others. It is printed both in French and English in parallel columns. The author says that in this book there is no attempt to advance or discuss theories, results only being described, and the means by which they have been obtained. It is the answer to the enquiries of nearly a thousand correspondents who have asked for information, and is intended to enable others to understand what has been done. The phonopore, as probably many of our readers know, is the outcome of an endeavour on the part of Mr. Langdon-Davies to utilise induction effects which, in the telephone, are so objectionable.

Jamaica Exhibition.—The exhibition at Jamaica was formally opened on January 27th by Prince George of Wales. The exhibition has been arranged under the general management of Mr. S. Lee Bapty. The exhibition grounds are situated at the north of the city of Kingston upon the race track. It is a charming spot, about a mile and a half from the harbour, covering over 23 acres, and flanked by the Blue Mountains. Along the roof and sides of the exhibition building red and yellow electric lights alternate, while within electric lights of red, yellow, and blue add to the beauty of the somewhat Oriental scene. The gardens around the building are beautifully laid out with pretty walks. The English display, next to the native exhibit, is the largest and most successful. All Kingston was *en fête* for the occasion, the public buildings being decorated with flags and flowers.

Electrically-Heated Printing Plates.—A novel and promising field for electric heaters has been tried in the Government printing and engraving office at Washington. The heaters invented by Dr. Leigh Burton, of Richmond, Virginia, are used instead of gas stoves for warming the plates for printing the bank notes, and apparently with much success. The plates have first to be warmed, when the ink is rubbed into the design after the manner of printing business cards. The ink is then cleaned off when the face of the plate is hot, and the impression taken. The objections to the employment of gas stoves as hitherto used are numerous, and the ease and cleanliness of the electric heater commend itself for extensive use in such work. In order that the attendants shall not be called upon to manipulate unaccustomed forms, the electric heaters are made to fit into the spaces occupied by the gas stoves.

Electric Tramways for Burton.—A largely attended meeting has been held in Burton to consider the application to introduce electric tramways into the borough. Mr. Slater, solicitor, of Darlaston, and Mr. E. Pritchard, C.E., of Birmingham, explained the details of the scheme for the promoters, and showed that there were no difficulties in the way of the construction or working of the line which could not be overcome. It was also pointed out that the Corporation, by the General Tramways Act, were thoroughly protected against loss, and that they were empowered to supervise the work and regulate the traffic. It was stated, however, that the Corporation could not work the line themselves except by obtaining a special Act of Parliament. A resolution approving of the proposal was unanimously carried, and it was also decided to appoint a deputation to wait upon the Council and inform them of the feeling of the meeting.

City of London Pioneer Company.—As mentioned in our article last week, a company entitled The City of London Electric Lighting (Pioneer) Company, Limited, was brought out on Monday with a capital of £100,000 in £50 shares, to take up and work the contracts for the lighting of the City. The board of directors is: The Right Honourable Alderman Joseph Savory, Lord Mayor of London, chairman; His Grace the Duke of Marlborough, chairman of the Electric and General Investment Company, Limited; the Right Honourable the Earl of Suffolk and Berkshire, Charlton Hall, Malmesbury; the Honourable Alan Charteris, 23, St. James's-place, S.W., and Lloyd's, E.C.; J. Bevan Braithwaite, jun., Esq., director of the Electric and General Investment Company, Limited. Consulting engineer: Major-General C. E. Webber, C.B. J. Cecil Bull, Esq., secretary. Offices, 1 and 2, Great Winchester-street, E.C. We believe the capital was considerably over-subscribed, and there is a whisper that shares are already at a considerable premium.

Bibliotheca Polytechnica.—It is sometimes necessary for professional engineers to turn up at once the best authorities on certain subjects, whether in English or in foreign languages. A work embodying much industry and research has been published, entitled "Bibliotheca Polytechnica, a Directory of Technical Literature," being a classified catalogue of all books, annuals, and journals published in England, America, France, and Germany, including their relation to legislation, hygiene, and daily life. Edited by Fritz von Szczepanski. (London: Sampson Low, Marston, and Co.; price 2s.) The catchwords are given in three languages (English, French, and German), so that readers of every nationality can at once turn to the branch he seeks in the literature of the latest investigations. An exhaustive enumeration of the technical journals in the three great languages of the world is also given. We should imagine the book will prove exceedingly useful, and as there is a promise of an annual issue, the information will be constantly kept up to date.

Electric Treatment of Wine.—In the Paris Exhibition M. de Meritens, of the firm of early dynamo fame, showed a process of ripening wine which seems to be attracting attention in practical circles, and may possibly be adopted in the treatment of wines for use. It is a question of the destruction of the microbes of ferment. In sending a continuous current through a liquid the microbes would certainly be destroyed, but some of the liquid—wine in this case—would be dissociated into gas and its bouquet is destroyed. By the use of alternate currents M. de Meritens obviates any disadvantages in the employment of electric currents and yet destroys the microbes. In this process the wine is allowed to percolate through tubes in which are fitted silver-plated diaphragms with numerous holes punched therein, alternate discs having their holes punched in a different patterns to ensure a movement of the liquid passing. Alternate sets of the plates are connected together in parallel, and alternate currents of low potential are passed while the wine circulates through the tubes. Specimens of the plates were given to us when at the Paris Exhibition and the process exhibited in action, but its usefulness for Britain is naturally very limited.

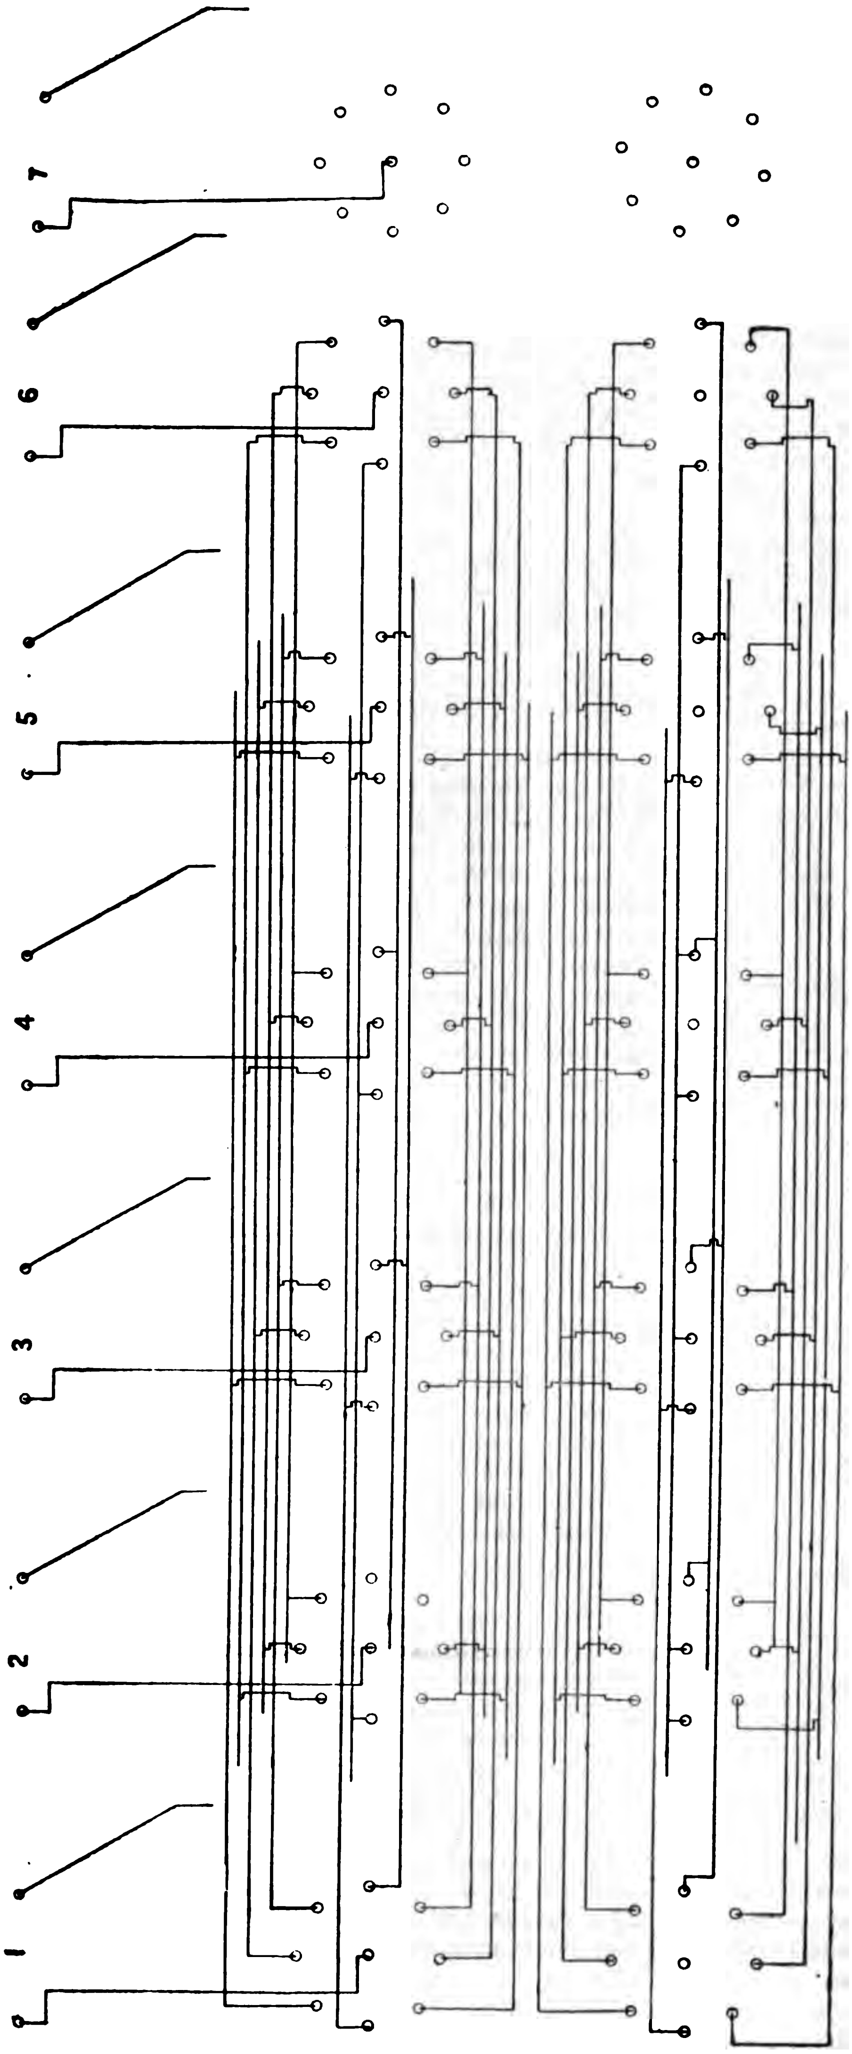
The Liverpool Overhead Railway.—The half-yearly meeting of the Liverpool Overhead Railway Company shareholders was held at Liverpool on Tuesday. Sir W. B. Forward, chairman, explained that the delay in construction had taken place mainly through the non-delivery of material. The progress now, however, was fairly rapid. The line, which is to be 5½ miles in length, along the dock line, is complete for one mile, from its northern extremity, and foundations have been laid to the centre of the city. It was hoped the northern section would be at work by October. Electricity was proposed as a motive power, and tenders from four engineering firms were to be in by the end of the present month, being both for equipping the railway and working it. Quoting from American experience, he showed the probable enormous growth of the traffic on the line, and anticipated no difficulty in paying a good dividend. Further calls of £1 per share would be made in April and July. The report and accounts were adopted, and the retiring directors were re-elected. The chairman, replying to a vote of thanks, expressed the opinion that not many years hence the Liverpool Overhead Railway would be looked upon as the best railway property in Lancashire.

Life of Incandescent Lamps.—We are in receipt of a new American technical journal, *Electrical Enterprise*, published in Boston. In one of the first numbers we notice the following sensible remarks upon the life of incandescent lamps as affected by the means of producing the vacuum: "In the processes of manufacturing incandescent lamps there are as many devices, secrets, kinds, and methods as there are varieties of lamps. In one particular they all agree, and that is in heating the carbon filament during exhaustion. That in this portion of the process, so necessary to the production of the perfect lamp, there may be conditions whereby the filament can be injured, has recently been brought to the attention of electricians by the development of mechanical quick-acting air pumps. With these a fairly good vacuum was obtained in a few minutes, and then the current was turned on to expel the air and the exhaustion continued. These lamps showed both higher efficiency and longer life than other lamps made from similar filaments, but exhausted in the usual way, where possibly not nearly as good a vacuum had been obtained by the mercury pump when the current was turned on. The filaments in the latter case were possibly partially consumed and disintegrated in the rarefied atmosphere. It is a question well worthy of study, whether lamps as manufactured in quantities to-day are not injured by heating the filaments to incandescence before nearly all the air has been removed."

Secondary Batteries.—Dr. J. H. Gladstone and Mr. Hibbert have been experimenting on the effect of adding sodium sulphate to secondary batteries, and have communicated the results to the *Phil. Mag.* [5], 30. We take the following condensed account of the experiments from the "Abstracts" in the January number of the Chemical Society's *Journal*: "The addition of sodium sulphate to the acid solution of an ordinary secondary battery is known to be of considerable advantage to the working of the cell. The authors find that in this case a large proportion of sodium sulphate is formed in close contact with the lead sulphate at the cathode, and they show that this would be favourable to the reduction of the latter substance, as a paste made of equal parts of red lead and lead sulphate is more readily reduced in a solution of normal sodium sulphate than in dilute sulphuric acid. They find also that the presence of sodium sulphate diminishes the local action arising between the acid and different parts of the plates. No indication could be found of the formation of either of Frankland's sub-sulphates of lead on treating litharge with dilute sulphuric acid, and the authors believe the ordinary sulphate of lead to be the substance produced in the voltaic reaction. The high initial E.M.F. observed in a secondary battery when the charging current has just been stopped is shown to be due to inequalities in the acid strength produced by the current. An increase in the strength of the acid surrounding the positive (peroxide) plate is found to take place, and this causes the abnormal E.M.F., which gradually disappears as the strength of the acid is equalised by diffusion."

International Niagara Commission.—The Cataract Construction Company, having invited various firms to send in projects for the utilisation of about 125,000 h.p. at Niagara, and its distribution, partly to an industrial district in the neighbourhood of the Falls, and partly to the town of Buffalo, appointed an international commission to adjudicate on the plans sent in. This commission consisted of Sir William Thomson, F.R.S., president; Dr. Coleman Sellers, Professor of Engineering Practice at the Stevens' Institute of Technology, Hoboken, N.J.; Prof. E. Mascart, Membre de l'Institut, Paris, and Directeur du Bureau Central Météorologique; Colonel Th. Turrettini, Directeur des Travaux d'Utilisation des Forces Motrices du Rhone à Genève. After a careful examination of a large number of projects sent in, in accordance with the letter of invitation of the Cataract Company, the commission have awarded the following prizes—Projects combining the development of power and its distribution. First prize: Not awarded. One second prize: To the scheme of Messrs. Faesch and Piccard, Geneva, and Messrs. Cuenod, Sautter, and Co., Geneva. Four third prizes: To the projects of Mr. A. Hillairet and Mr. Bouvier, Paris; Mr. Victor Popp, Paris, and Prof. Riedler, Berlin; Prof. L. Tigreux and Mr. L. Levy, Paris; the Pelton Water Wheel Company, San Francisco, Cal., and Norwalk Iron Works Company, S. Norwalk, Conn. Projects for the hydraulic development of the power—First prize: To the project of Messrs. Escher Wyss and Co., Zurich. Two second prizes: To the projects of Messrs. Ganz and Co., Budapest; Prof. A. Lupton, Leeds, and Mr. J. Sturgeon. Projects for the distribution of the power: No prize awarded.

Ipswich.—At the last meeting of the Ipswich Lighting Committee a letter from the Ipswich Electricity Supply Company to the Mayor asking for reconsideration of their demands, which were originally recommended for consent in conjunction with Messrs. Laurence, Scott, and Co., but which, owing it was maintained to misstatements, the Council had set aside. The Mayor said he did not like bringing up a thing that was settled, but he thought this company had been hardly dealt with. In the course of a further conversation the vice-chairman demurred to bringing the matter up again, and Mr. Brand argued that it would be wrong to have more than one company in operation; and further, that it would always be open to the Corporation, if they chose, to go for an order for power themselves to light the streets with electricity. Eventually, the Mayor said he should confer with the town clerk as to placing the notice on the agenda paper for the Council meeting, and the town clerk intimated that he should advise a notice to read the letter and consent to the order if thought advisable. The town clerk next read a letter from the Board of Trade enclosing a copy of a letter from the agent to the promoters of the order applied for by Laurence and Scott, Limited. The promoters agreed to make the alterations desired in the first resolution passed by the Town Council on January 7, those being the conditions on which the consent of the Corporation was given. As to the other resolutions: that the committee secure such a modification of the draft order as would give the Urban Sanitary Authority power to acquire the undertaking after 10 years instead of 42 years, and making the dividends vary in inverse ratio to the rates charged, the promoters did not see their way to agree to either proposition. Mr. Brand hoped someone would give them the electric light before long. He did not care who it was. The town clerk said he had seen the officials of the Board of Trade on the subject, and was told by them that the course pursued by the Board was to get the promoters and the Sanitary Authority to agree between themselves whenever they could, and it was added that if they did not agree the Board would deal with it very shortly, as their minds were made up. In the end it was agreed to report that the letter had been received, and that in the opinion of the committee it was not desirable to go to any expense in the matter.



POST OFFICE INSTALLATION. FIG. 5.—Connections of Dynamo Switches.

POST OFFICE INSTALLATION.

We herewith continue the illustrations of the details of this installation, and shall in our next issue consider the work as a whole.

Fig. 5 shows the connections of the dynamo switches, and Fig. 6 shows details of the fuse-chamber board.

Fig. 7 shows the elevation of the fuse-board one-eighth full size. The details (Fig. 6) are one half full size.

Fig. 8 shows the interchangeable dynamo switch one-quarter full size.

ELECTROLYSIS OF SILVER SALTS.

BY ALEXANDER WATT.

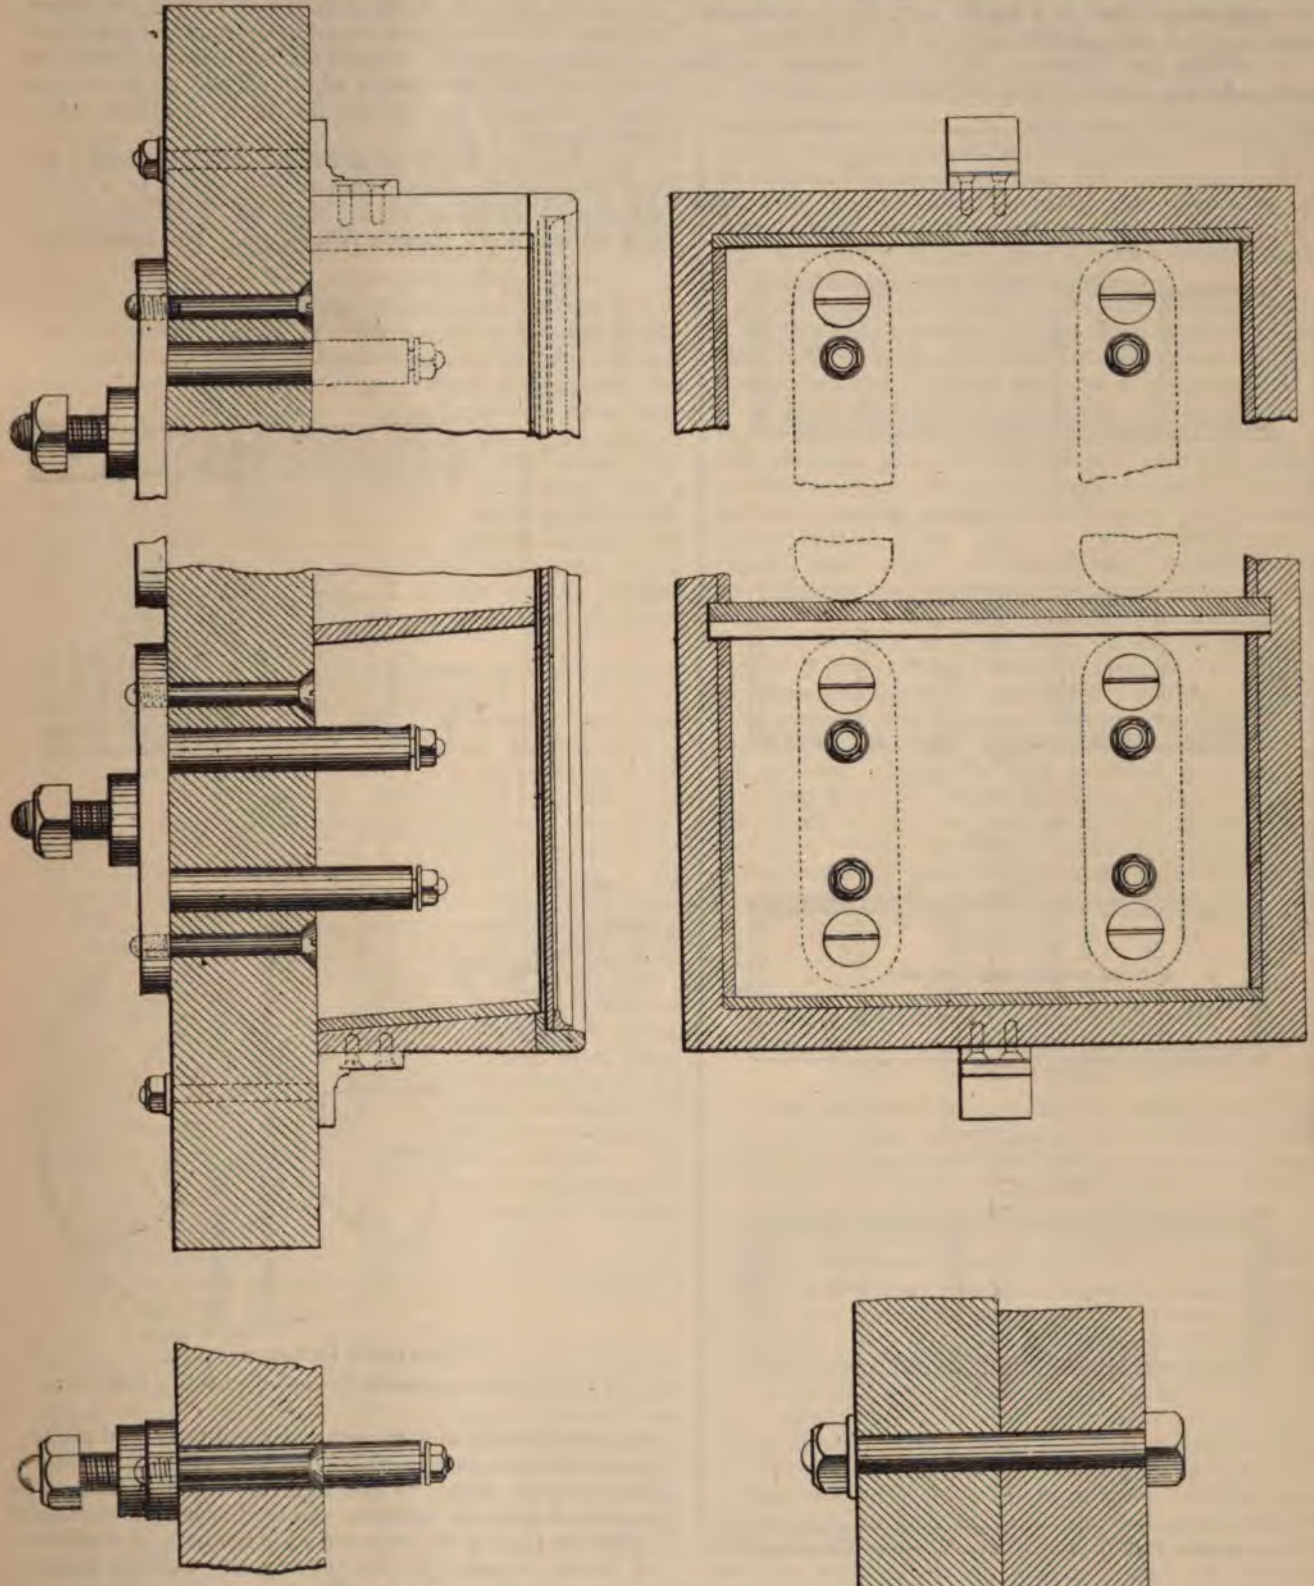
(Continued from page 7.)

In the following, and some subsequent experiments, an endeavour was made to determine whether it would be possible to obtain a satisfactory electrolyte from what may be termed *acid* solutions, in contradistinction to the ordinary alkaline solutions used in electro-plating, which could be useful for some purposes in the electrodeposition of silver. Well knowing the difficulties which usually present themselves when dealing with such solutions electrolytically, the subject was not approached without considerable misgivings. Having been successful, however, in depositing alloys of metals from mixed solutions of non-alkaline metallic salts, the writer indulged a faint hope that possibly a few trials in the direction indicated might lead to more or less favourable results.

13. *Sulphate of Silver.*—A solution of this salt was prepared by digesting moist carbonate of silver in a moderately strong solution of sulphuric acid, and the resulting solution was afterwards diluted with water, the proportions of acid and water being 500 parts of the latter to each five parts of the former. The solution thus prepared was then tried with the current from a single Daniell cell, a clean brass plate being used as the cathode, when, in a few moments after immersion, the plate received a film of a golden-yellow colour, the deposit gradually becoming grey and of a granular character, the particles of which fell from the plate when it was gently moved in the bath. When the plate had been immersed for about 10 minutes or so, spongy metal commenced to form at its lower corners. A further addition of water was then made to the solution, and a newly prepared plate immersed, but even in this very weak solution the metal still refused to deposit in the reguline form, with the exception of a thin film of white metal, which in each case was found attached to the plate after the non-reguline deposits had been removed. A solution of the sulphate was next prepared by double decomposition, from mixed solutions of

nitrate of silver and sulphate of soda, and the resulting precipitate of sulphate of silver then treated with water until a saturated (though weak) solution of the sulphate was obtained, which was then electrolysed as before with the current from one cell. In this case, as in the preceding, the brass plate became promptly coated with a golden-yellow film, and there was no disposition whatever (except a very slight film of white metal adhering to the brass) for the metal to deposit in a reguline condition.

14. *Sulphate of Silver by Electrolysis.*—It was next determined to ascertain the behaviour of silver sulphate when prepared by electrolysis, by which the varying degrees of acidity of the bath could be noted, and their effects upon the character of the deposit more closely observed. For this purpose a solution of sulphuric acid was prepared by adding five parts of the acid to each 500 parts of the water used. A silver anode, and brass plate for cathode being placed in this liquid, the current from two Daniells was allowed to pass, when, in a few seconds after, the brass plate gradually assumed the golden-yellow colour, indicating the presence of silver in the solution, and in about a quarter of an hour or so a spongy deposit of silver was found to have formed at each of the lower corners of the plate. When this loose form of metal was rubbed off the plate with the finger, a slight film of white silver as before was found beneath, and which adhered firmly to the brass surface of the cathode.

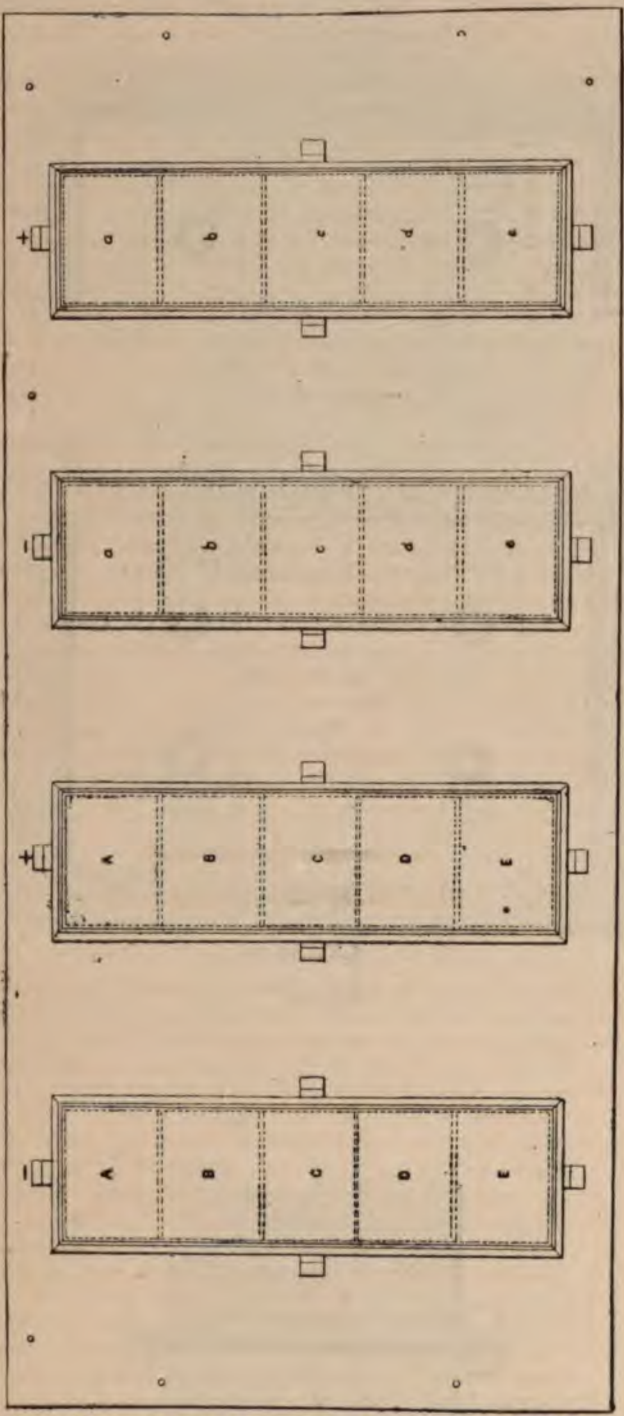


POST OFFICE INSTALLATION. FIG. 6.—Fuse Chamber Board. Details.

15. *Sulphates of Silver and Alumina, Etc.*—It was now resolved to ascertain if the addition of other sulphates, from which their metals are not reducible by electrolysis,

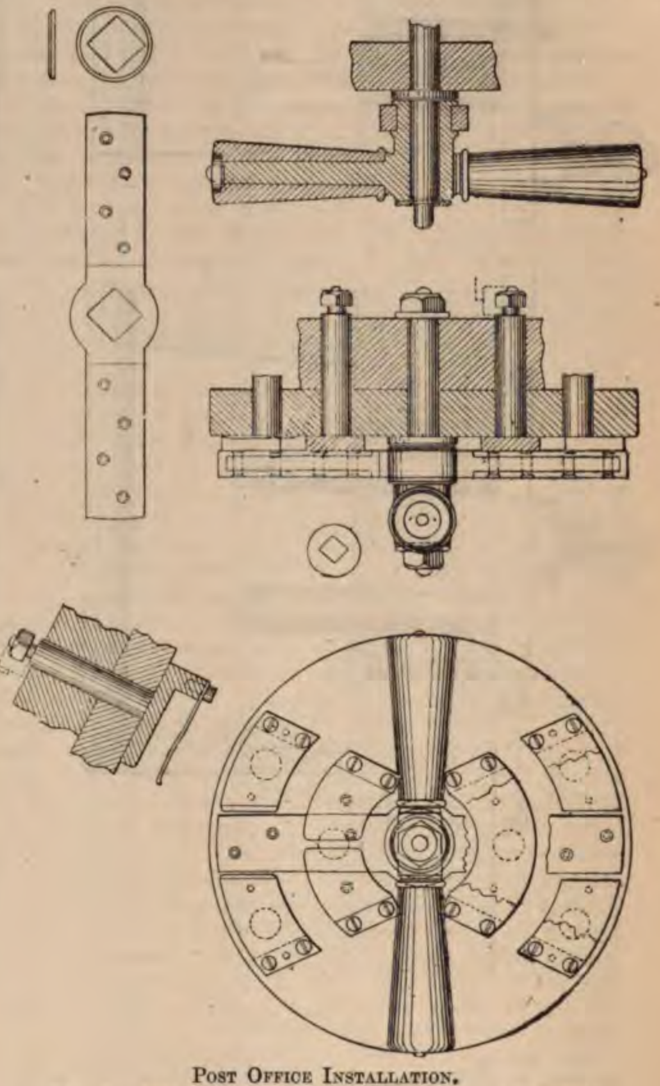
would have a tendency to check the formation of non-reguline silver upon the cathode. With this end in view, a solution of sulphate of alumina was first added to one of sulphate of silver, and the compound liquid then tried with the current from a single Daniell cell, but it was found that the silver still refused to deposit in a proper condition. Sulphate of magnesia, ammonia, and bisulphate of potassa were afterwards tried in a similar way, but no favourable results followed these modifications of the electrolyte.

16. *Sulphate and Nitrate of Silver.*—A solution of the mixed salts was obtained electrolytically, as follows: An acid solution was formed of nitric acid five parts, and water 500 parts; in this was immersed a silver anode connected to a single Daniell and a brass cathode, when in a very few seconds a black film formed on the brass surface, which, on being rubbed off the plate, exposed a slight film of silver attached to the brass. To the above solution was next added a weak solution of sulphuric acid (five in 500 parts), and the mixed solution was then tried with the same current, when it was found that a grey deposit of silver quickly formed, but, excepting the slight film of reguline metal before noticed, the metal, which deposited with considerable rapidity, persistently assumed the spongy character, and when the plate had been left undisturbed for about half an hour a mass of spongy metal was found at the bottom of the vessel, which nearly approached the anode. The solution was next diluted with about 250 parts of water, when a fresh plate became coated with a yellow film immediately after immersion. A similar addition of water was again made, the anode surface reduced, and a long thin iron wire interposed in the circuit, under which conditions, although the same yellow deposit reappeared, it was found to be firmly adherent, whereas all the previous deposits of a like character were easily wiped off the plate with the finger. Beneath the yellow film, as before, there was a white deposit of silver.



Post Office Installation. Fig. 7.—Fuse Chamber Board.

17. *Ammonio-Nitrate of Silver.*—A solution of this salt was prepared by adding ammonia in excess to a strong solution of nitrate of silver, until the oxide of silver at first thrown down became redissolved. This solution was then considerably diluted with water and the liquid electrolysed with the current from one cell, when it was found that metallic silver, in the form of a fine powder, was deposited upon the cathode, and readily became dislodged when the plate was gently moved in the bath. An addition of nitrate of ammonia was next given and the solution further diluted, but no modification of the solution or of the current induced the metal to assume the reguline condition beyond a mere film which attached itself to, but did not alloy with, the brass plate.



Post Office Installation.
Fig. 8.—Interchangeable Dynamo Switch. ¼ Full Size.

18. *Ammonio-Sulphate of Silver.*—A bath was formed by adding recently precipitated and moist sulphate of silver to a warm solution of ammonia (one part ammonia to two parts water), the mixture being repeatedly agitated for a few minutes. The clear liquid being decanted from the undissolved sulphate was then diluted with water, and the solution electrolysed with the current from one Daniell. The deposition from this solution was pretty quick, but the

silver was of a rather dark colour, and after a short immersion of the plate it was found that a film of an uniform brown colour had deposited upon the first layer of reguline metal, and when the plate was gently rubbed the brown film readily came away, exposing a film of white metal on the brass surface. Even when this solution was considerably diluted, the deposited metal, at first bright and reguline, gradually became coated with a brown, and, indeed, almost black film, which was especially dark in colour at the lower corners of the plate.

19. *Ammonio-Chloride of Silver.*—A solution of this salt was prepared by dissolving moist chloride of silver in strong liquid ammonia, the solution being afterwards diluted with water. With the current from two cells, metallic silver, in a spongy form, was deposited upon the negative plate, and the metal gradually assumed a bright crystalline appearance at the extreme edges of the spongy metal. No modification of the solution or of the current could induce the metal to assume the reguline form.

20. *Chlorides of Silver and Ammonium.*—To form a bath of this combination moist chloride of silver was dissolved in a strong solution of salammoniac, and the solution was afterwards diluted with water. When electrolysed with the current from two cells, a white deposit of silver soon formed upon the brass plate, but a short time after it was found that the electrolytic action had ceased. On examining the anode it was found to be covered with a firmly adherent film of a dark colour, which was with difficulty dislodged from the plate. A portion of this film, after being washed, was treated with nitric acid, which produced no effect upon it. A further portion, treated with strong ammonia, became dissolved; the salt, therefore, was probably a subchloride of silver.

21. *Chlorides of Silver and Ammonium by Electrolysis.*—A moderately strong solution of salammoniac was first prepared, in which was then placed a silver anode and brass cathode, as before, and the current from two Daniells in series passed through the liquid. In about four or five minutes a white deposit of silver formed upon the brass surface, but, as in the last case, the anode soon became iridescent, then blackened, and in a few minutes after the current stopped. Liquid ammonia was then added to the solution, and the anode cleaned, when white metal again deposited upon the cathode; a few minutes after, however, the current again stopped, and the anode once more appeared coated with the film of subchloride.

21. *Phosphate of Silver.*—A solution of this salt was prepared by dissolving moist carbonate of silver in a strong solution of phosphoric acid. The solution, after being moderately diluted with water, was electrolysed with the current from one cell, when a somewhat iridescent film quickly formed upon the brass plate, the deposit eventually exhibiting brown patches on both sides of the plate. On rubbing the plate with the finger the brown deposit readily became dislodged, when a film of white metal, as so often noticed before, appeared on the surface beneath. A good reguline deposit, however, could not be obtained from this solution by any subsequent modification of the strength of the bath or of the current.

22. *Mucate of Silver.*—A bath of this salt was prepared by digesting moist carbonate of silver in a strong solution of mucic acid. With the current from one cell only a slight patchy film of silver appeared on a freshly-cleaned brass plate. A second cell being introduced, deposition was much quicker, but it was soon found that the white metal at first deposited was succeeded by the brown variety of the metal. This solution was a rather poor conductor, and whether used in its more concentrated form or diluted, it failed to yield a fair deposit of reguline metal.

23. *Permanganate of Silver.*—To form a bath of this salt, a solution of nitrate of silver was added to one of permanganate of potassa, and the crystalline salt which subsequently formed was then dissolved in water, and electrolysed with the current from two Daniells, when an iridescent film at once formed on the cathode, which on being removed exposed a film of white metal beneath, but beyond this no satisfactory result could be obtained.

24. *Sulphocyanides of Silver and Potassium.*—A solution was prepared by dissolving carbonate of silver in a strong solution of sulphocyanide of potassium, the latter being in excess to prevent the sulphocyanide from being thrown down when the liquid was diluted with water. The diluted solution, electrolysed with the current from one cell, yielded a very quick deposit, somewhat iridescent at first, but the metal gradually became white and very bright; indeed, the deposit remained bright during about half an hour's immersion of the plate, after which period, however, it slowly became dull and of a darkish colour. The metal, however, after being scratch-brushed, presented the usual appearance of electro-deposited silver, and was very firmly adherent to the brass surface.

24. *Salicylate of Silver.*—A solution was prepared by digesting carbonate of silver in a strong warm solution of salicylic acid, in which the carbonate slowly dissolved. When cold the solution was separated from the uncombined acid and carbonate present, and after being again warmed was electrolysed with the current from two cells, when an iridescent film slowly formed upon a brass cathode, beneath which was found a grey film of silver.

It will have been noticed, in perusing the details of some of the foregoing experiments, that from many of the solutions tried the metal, after the first white film of silver had become deposited, assumed the form of a non-metallic film of a golden-yellow or brownish colour, and that this deposit was readily removed from the plate by slight rubbing. In most instances the golden-yellow film gradually darkened to a brown colour, and after a longer immersion of the plate this was generally succeeded in its turn by a deposit of spongy metal. From this it is inferred that the yellow film and its subsequent modifications of brown, more or less dark in colour, was in reality metallic silver in a highly-comminuted condition, the character of which may ultimately merge into the granular state of a grey colour, a blackish powder of non-metallic appearance, or a group of agglomerated particles of a spongy form, while in some instances, as before observed, crystals of bright silver are found to spring out from the edges of the spongy mass. It may be here remarked, in passing, that the writer has before called attention, when treating of the electrolysis of tin, lead, and some other metals, that the crystalline form of metal invariably succeeds the spongy condition provided the vessel in which the operation is conducted be allowed to remain undisturbed.

(To be continued.)

UNDERGROUND MAINS.—IV.

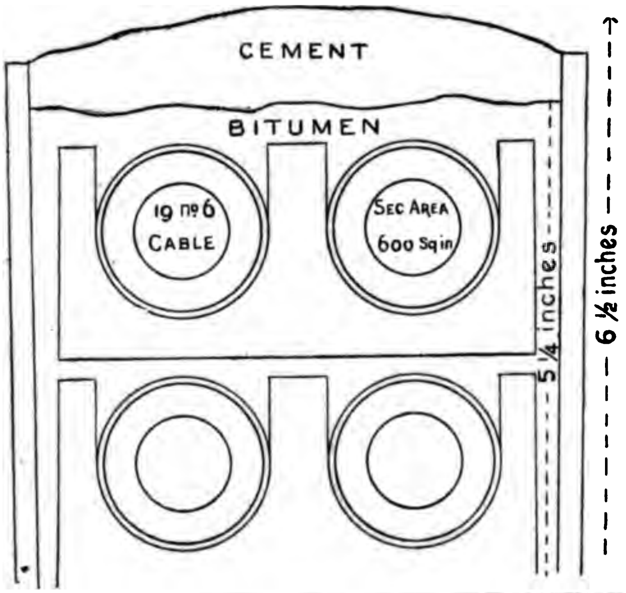
THE CALLENDER SOLID SYSTEM.

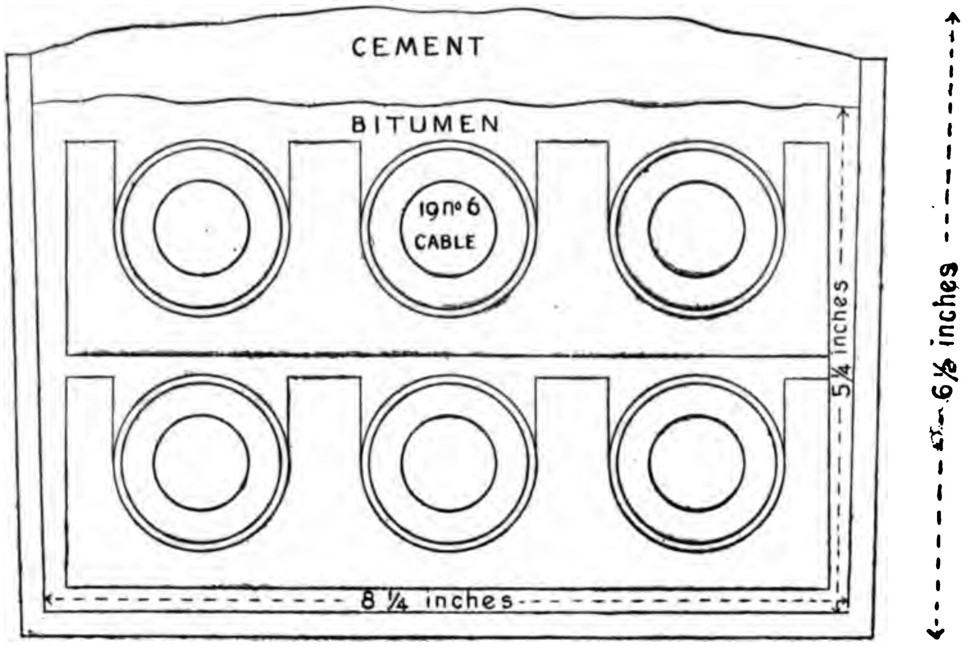
In the Callender solid system of underground electric mains, the cables, heavily insulated, are laid in suitable troughs, generally of cast iron, placed in trenches under the street, and the whole of the vacant space in the trough round the cables is run in solid with refined bitumen. All the bitumen employed is genuine natural Trinidad bitumen, free from any admixture of gas, tar, and pitch.

The whole forms a solid and compact mass, into which neither gas nor water can possibly penetrate, and which itself forms a very high electrical insulation. There are few substances more durable than this bitumen, and with cables thus embedded there is little probability of any deterioration taking place in mains when once laid, while the thorough mechanical protection which is ensured reduces to a minimum the liability of injury from exterior causes.

Mains laid on this plan are permanent, and form a sound engineering job. It is of course clear that such mains should only be laid when the conditions do not require that the capacity of the cables should be afterwards altered. The Callender solid system is especially suitable for connecting mains for isolated plants where the conditions are settled and well known; for heavy mains in large cities where the consumption is likely to attain its maximum at once; for heavy distributing networks; and for the heavy feeders which are run to various points of the system of three-wire distribution. It is also peculiarly suitable for arc lighting on the series system where long lengths of single or double mains are required to be run.

The combination of vulcanised bitumen as the insulation for the cable itself, with plain bitumen run around it as a sheath in the trough, is one that ensures an absolutely safe and constant insulation, on which faults are unlikely to appear. Repairs, when necessary, are easily and rapidly made. Altogether, it forms one of the most trustworthy and satisfactory methods of placing cables underground, and has a certainty of being more permanent and lasting than most of the other parts of an electric lighting plant. The work of laying, once done, is thorough and complete.





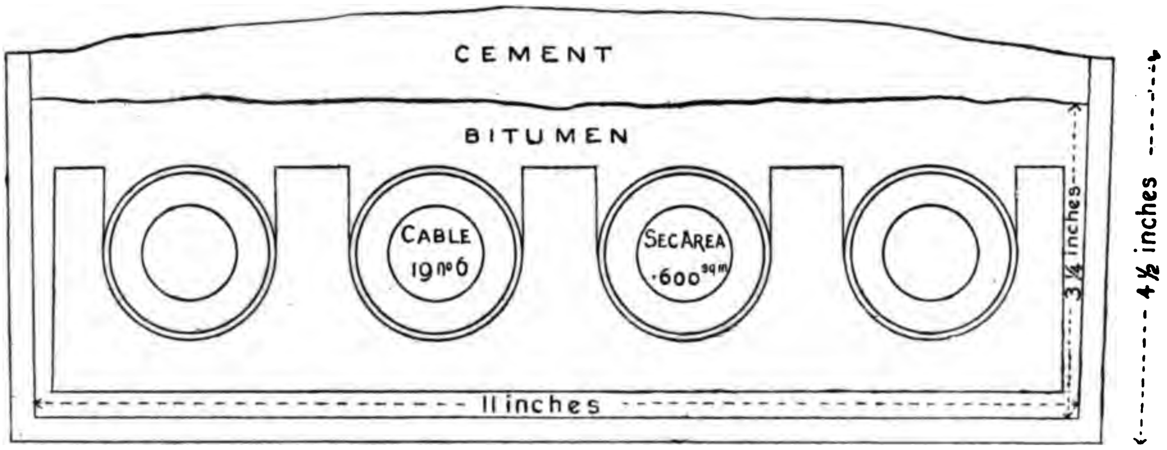


Fig. 1.—Callender Solid System of Underground Mains. Sections of 4 and 6-way mains in trough with cement cover.

The troughs for the mains are made of cast iron. For town work this is especially preferable, as it offers a permanent protection from the picks of workmen of other companies. In some cases the upper surface of the trough having been filled nearly to the level by bitumen, is covered by a layer of cement. In others the trough is covered in with cast-iron lids. The thickness of the metal is from $\frac{3}{16}$in. to $\frac{5}{16}$in., varying with the size of the trough and the liability of the soil to disturbance. These iron troughs are made in lengths of 6ft., having socket pieces cast on one end, so that when fitted together the surface inside the trough is of one level. For carrying the mains round corners, and for changing levels at crossings, circular pieces and curved troughs are made, but considerable deviation from the straight line is possible with the ordinary type.

In country roads, and in places where wood is plentiful, troughs of sound timber are often substituted for those of cast iron, care being taken to select wood which will stand underground without rotting. The planks should not be less than ¾in., and the lid should be of 1in. stuff. It is not advisable to use creosoted wood, as the action of the products of coal-tar distillation are found to be injurious to nearly every form of dielectric.

Brick and cement trenches are occasionally used for special situations, but they are expensive, and offer no advantages over those of cast iron.

The ordinary shapes and sizes of mains on the Callender solid system are shown in Fig. 1, which comprises sections of four-way and six-way insulated mains, laid in bitumen in iron troughs and covered over at the top with cement.

A very usual case in a distributing network is where a pair of heavy feeders to a distant point are run along with the distributing mains in the same trough. This arrangement is shown in Fig. 2. In both cases the position of the cables in the trough is kept by bridges of hard bitumenised wood of the shape shown, which are first thoroughly dessicated, and then saturated with bitumen. These prevent the cable from touching the bottom of the trough, or of accidentally shifting their relative positions.

In Fig. 3 is shown a pair of heavy feeders, 91 strands of No. 9 wire. These are highly insulated, and each covered with outer lead casing; then laid one above the other in solid bitumen in a narrow iron trough, and covered in with cast-iron lid. The joint of the trough is shown in section below.

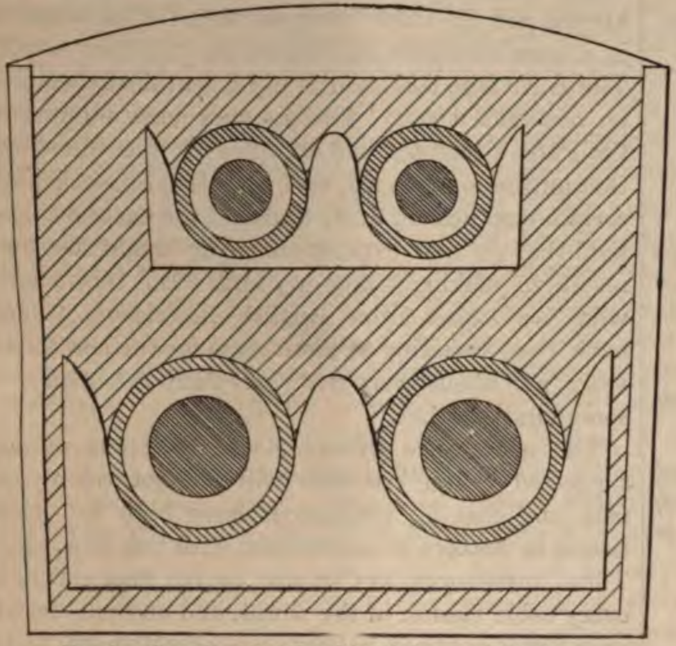

Fig. 2.—Trough containing Distributors and Feeders.

In actual practice the method of laying is as follows:

The trenches in the ground having been dug and levelled, the iron troughs are laid therein, and are jointed together in one length with countersunk bolts and nuts, Fig. 4.

Bitumen is meanwhile being heated in the cauldrons, and a little of this run along the bottom of the trough. While still molten, the bitumenised wood bridges are pressed into place across the trough at intervals of 18in. apart. When the bitumen is set, the cable, which has been brought on huge drums, is paid out into the trenches, and laid along into the spaces of the wooden bridges. The cable is then drawn taut, and melted bitumen is poured in between the cables and between the cables and the sides of the trough.

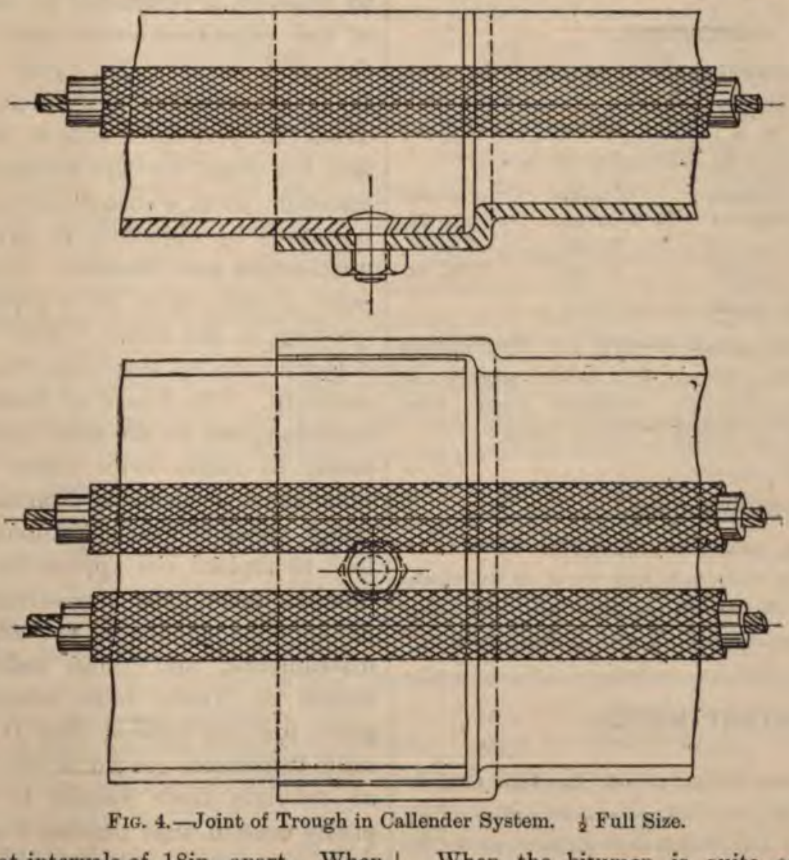

Fig. 4.—Joint of Trough in Callender System. ½ Full Size.

This is done by moving the bitumen cauldron on wheels along the trench, and by means of a large ladle, pouring a little molten bitumen in at a time. When this first layer is cool, the men come back again and pour in a little more, and so on, for about six times, thus allowing the bitumen to fill up every cavity round the cables. In the case of cables above one another, the whole process is, of course, repeated along the length. The bitumen is run in to within an inch of the top of the trough.

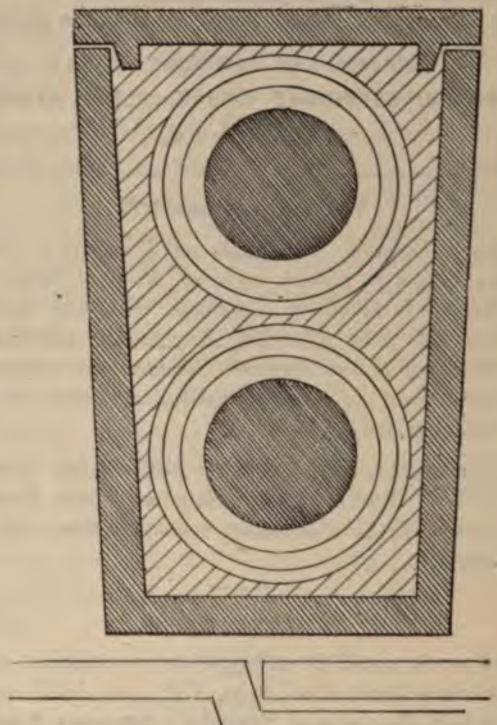

Fig. 3.—$^{91}/_{9}$ Lead Covered Cable. ½ Full Size.

When the bitumen is quite cold a layer of Portland cement from 1in. to 3in. thick, according to circumstances, is put upon the top of the bitumen, and where crossing a roadway a brickwork, cast-iron, or other protection is placed over the top, to guard against damage from heavy traffic.

Editorial and Publishing Offices :
139-140, SALISBURY COURT, FLEET STREET,
LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms :—*

	3 months	6 months	12 months.
United Kingdom............	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d	17s. 4d.
Other Places..................	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court Fleet Street, London, and be crossed " Union Bank."*

BOUND VOLUMES.

Vols. I. to VI. inclusive, new series, of "The Electrical Engineer" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

We may occasionally follow the lead of our American Contemporaries, especially when they point out a serviceable way. They are not backward in asking their friends to do all they can for the welfare of the paper. We ask our friends to remember us. No Paper that we know ever refuses Subscribers or Advertisers. Nor do we; in fact, we invite them, believing that they will get full value for their money.

Specimen copies of the paper will be sent on request.

THE BOARD OF TRADE AND STANDARDS.

As might have been expected, the report of the Standards Committee, as foreshadowed in the statement given elsewhere in our columns, will come practically to saying we authoritatively adopt the C.G.S. system and the Paris Congress ohm. This adoption is a pure formality, and leaves us "as you were." The B.A. standard ohm is not scientifically exact—no one said it was. The mercury unit adopted at the Paris Congress, and accepted by the Standards Committee, is not exact, and, what is more, we believe certain electricians, J. T. Sprague, for example, contend that no two experiments can obtain the same results in making a mercury unit. But this is only what we expect from English electricians. They have been tinkering at these units for the last thirty years, and about every five years there is a change of some kind or other.

The acceptance by the Board of Trade of any suggested "ohm" as unit will not get rid of one fact, and that is, resistances have been for years issued by makers in accordance with the B.A. ohm. These resistances are in use in the Post Office, in every cable station in the world, and any new resistance-boxes required in such offices will have to be made to agree with these old resistances. There is no logical reason why resistances in agreement with the B.A. ohm should not be generally and universally accepted. The only result of adopting another unit will be to add to the work of those who use the old units, as if there was not enough work in the world now. A man wants to measure a resistance in ohms, and he has one of the resistance-boxes made in agreement with the B.A. unit. He gets his resistance, and then, forsooth, has, if connected with the Board of Trade, to perform a sum in arithmetic, or to translate his result for the edification of a lot of ultra-scientific men, whose object is to make themselves notorious by objecting to everything "that is" as unscientific and illogical. From a purely scientific point of view, there is no objection to pursuing this question of the exact "ohm" to finality—the only objection is to the changing of the commercial standard. The Board of Trade, if it has to do with anything, has to do with commercial matters, and ought to think twice before occupying a position that must lead to complication. Will the Post Office spend a hundred thousand pounds, more or less, to replace old apparatus with new, or will its officials insist upon measurements being tabulated in two columns—those actually ascertained by the instruments, and those calculated because the Board of Trade have adopted the Paris Congress unit as against the B.A. unit? Will the cable companies get rid of all their resistance-boxes or tabulate their results in duplicate? We are pretty certain that neither the Post Office nor the cable companies will trouble themselves one iota about the new unit, but go contentedly along measuring as they have measured in past years, and ignoring the new broom. If there had not been a large number of resistances in use, or if "resistances" had come in with electric lighting, then the "legal ohm" would have been as good as any other, except it should prove somewhat difficult of duplication.

We may even go farther, and say the adoption of the new standard by the "Board of Trade" will not necessarily involve the manufacture of the new standard. The old B.A. ohm may be used, and the results translated for the edification of the Board's officials, although it would save trouble if those who have to buy new resistances were to have them in accordance with the requirements. This change to the Paris Congress unit is something like a change in railway gauge would be from the normal, say, to a 5ft. gauge. None of the older lines would change, though new lines might adopt it, and the new gauge might scientifically be the better of the two. Once more, then, our objection is not to the introduction of the Paris unit as being a more scientifically accurate unit than the B.A. unit, but to its introduction as a commercial unit, from which no earthly benefit can arise. It means simply the substitution of one "arbitrary unit" for another "arbitrary unit"; and we are further inclined to agree with those who say that the substitution should not take place, because it is not so easy to reproduce the mercury resistance as it is the B.A. resistance.

LEEDS.

"The Leeds Municipality will have a bad record when the annals of electric lighting are written." Such is the statement of a local paper, when commenting upon the vacillation and procrastination of the authorities. It would be interesting to hear the opinions of such men as Wilson Hartnell and Mr. Crompton on this subject. If we mistake not, in years gone by Messrs. Crompton were active in attempting to introduce electric lighting into Leeds, and the result seems to be rather of the nature of "the cold shoulder." The contemporary making the above statement, goes on to say that the Municipality has, during the last three years, expended over £1,000 in considering the advisability of adopting the electric light, and has not arrived at a decision yet. More information is to be obtained, and more money expended. There is no reason for this delay, except the authorities at Leeds are in the condition of not knowing their own minds. Either they want the electric light or they do not. If they want it, the proper course to pursue is to employ a capable adviser, just as they would employ an adviser if a sewage scheme was under discussion or a new town hall to be built. Such names as Hopkinson, Kapp, Forbes, are not unknown as electrical engineers, and an appeal to an engineer who has made lighting a speciality would cost less than continual half-and-half measures. If the authorities do not want to take the lighting into their own hands, let one or other or all of the applicants for provisional orders have a free hand.

The questions before the authorities as to provisional orders are summed up thus: Must there be only one company? If so, which is best? What is to be the price of the light? What are to be the opportunities and terms of purchase afforded to the Corporation? As these questions concern all authorities when electric lighting is proposed, they may be briefly considered. Our answer to the first would be emphatic. One company and one only, unless the district was, like London, too large. Already in London mutterings of discontent are heard when one side of a street is in the hands of one company, and the other side in those of a second company. Again, when the time of purchase comes, negotiations with one company are preferable to negotiations with several. Authorities must decide as to the best company. The price will be stated by the applicant for the provisional order, and should be a maximum, not necessarily to be charged, and not permitted to be charged if the dividends to shareholders ranged above a certain agreed upon percentage. As regards purchase, there is only one just method, and that is to purchase the undertaking as a going concern at the valuation agreed upon by experts or by arbitration. Compulsory purchase at a fixed predetermined price is unjust, and will prove unworkable.

DUBLIN.

It is necessary to recur to this subject to say that the latest advices from Dublin are to the effect that the tenders of two companies, or rather tenders for a part of the work from each of two companies, have been accepted. We are, as yet, unable to give the exact portions of the work appropriated to each, but the favoured companies are:

1. The Electrical Company of Ireland.
2. The Irish House-to-House Electrical Company.

A reference to our issue of January 23 will show page 97, that the report of Messrs. Harty and Manville stated that "a good arrangement with two contractors might be made by selecting the Electrical Engineering Company of Ireland for the engines, boilers, and the public lighting plant, amounting to £16,033, and the Irish House-to-House Company for the alternators, regulating apparatus, transformers, meters, and cables, amounting to £15,244." It seems probable, then, that this suggestion has, in the end, been accepted, in preference to the giving of the whole work to the first named of these companies.

LIES.

Someone once said that a lie given 24 hours' start could never be overtaken. That seems to be true in connection with electrical matters, and especially with regard to electricity and fires. Only let an electric light wire be within a few miles (*à la* Artemus Ward) of the scene of accident, and forthwith the ubiquitous reporter to the local paper describes the conflagration as being caused by the electric light wires. No doubt careless workmanship has something, has much, indeed, to answer for in this direction, but the systematic jumping to this conclusion is "giving the dog a bad name," and is unmistakably stopping business. Novelists and writers in society papers are permitted to draw upon their imaginations—their productions would not be read were they not to do so—but the ordinary dry-as-dust penny a liner is supposed to be exact in his description, especially when he is "on the spot." Unfortunately the reporter is always on the spot, and as often has a go at electricity. It has struck some electrical engineers that "reporters" are almost to a man shareholders in "gas companies," and thus have unconsciously imbibed a bias against the rival illuminant. The most recent exemplification of diametrically opposed opinions is that at Cardiff. Men who sat at the table and saw the beginning of the fire, say it wasn't the electric apparatus; men who didn't sit at the table, but who were, of course, present, say it was; and those who were neither at the table nor present are in their conclusions divided. It did—it didn't. *Quien sabe.*

FERRANTI CENTRAL STATIONS.

A descriptive catalogue of the manufactures of Messrs. S. Z. de Ferranti and Co. has not hitherto been published. Their attention has, it seems, in great part been devoted to the supply of complete equipments for electric supply stations at home and abroad, which they have dealt with in each case specifically.

The enquiries, however, have become so numerous that the publication of a complete and ready catalogue of the plant and accessories required for electrical distribution on the Ferranti system has become necessary.

From the preface of this catalogue, which is to be issued shortly, we are able to quote the following information of some of the supply stations equipped with Ferranti plant, which will prove interesting to electrical engineers:

Grosvenor Gallery station, London.—This station was equipped with two alternators, and had as many as 35,000 lamps wired to the mains; the demand was such that the machines were frequently running for several hours at 50 per cent. more than their stated maximum output.
Deptford station is connected by four Ferranti concentric mains to various distributing stations which are now being completed in London. The capacity of the plant now erected at Deptford is 90,000 lamps, and this capacity is being increased by the building of two 200,000-light machines.
Rochester has a small station with a capacity of 3,000 lamps, which will shortly be extended.
Glasgow station has two alternators with a capacity of 6,000 lamps.
La Plata station, Argentine, has three alternators with a capacity of 9,000 lamps.
Rosario station, Argentine, has two alternators with a capacity of 6,000 lamps.
Barcelona station, Spain, has two alternators with a capacity of 6,000 lamps.
Municipal station, Paris, has three alternators with a capacity of 9,000 lamps.
Plaza de Toros, Paris, has one alternator with a capacity of 3,000 lamps.
Nancy has three alternators with a capacity of 9,000 lamps.
Havre has two alternators with a capacity of 12,000 lamps.
Melun has two alternators with a capacity of 6,000 lamps.
Troyes has two alternators with a capacity of 6,000 lamps.
Nimes has two alternators with a capacity of 6,000 lamps.
Dijon has one alternator with a capacity of 3,000 lamps.
Sens has one alternator with a capacity of 3,000 lamps.
St. Ceré has one alternator with a capacity of 600 lamps.

It may be pointed out that while a few of the smaller stations have been able to run continuously with single machines—*i.e.*, without reserve plant—their extension is either in hand or in contemplation.

Every facility is now afforded to contractors, supply companies, local authorities, and engineers requiring information upon the Ferranti system, and the company prefer, when possible, that their works at Charterhouse-square should be visited for that purpose.

SALFORD CORPORATION SEWAGE WORKS.

The Salford Corporation during the last year instituted an exhaustive series of experiments on the treatment of sewage, with the object of deciding on the most suitable system to adopt in the purification of the Salford sewage. In addition to the borough engineer (Mr. Arthur Jacob) the Corporation secured the services of Mr. Carter Bell, the borough analyst; Mr. John Newton, civil engineer; Dr. Burghardt and Mr. O. Giles, of Messrs. Mather and Platt's engineering works, to report on the various engineering, chemical, and electrical features of the systems experimented upon. The reports of these gentlemen have now been presented, and contain some interesting information. The magnitude of the question of the proper treatment of sewage and the difficulties involved in its accomplishment can scarcely be over-estimated. At the Local Government enquiry held with respect to the Manchester sewage scheme it was pointed out that the amount of sludge produced by the chemical treatment of sewage would be something like 200 tons per day. Although the Patent Office shows a record of many hundreds of attempts to deal with the sewage problem, it is one which is still far from being satisfactorily settled. So late as 1884 the Royal Commission which was appointed to enquire into the matter, after patiently investigating it for two years, had to report that "the efficient and effectual purification of sewage, according to our present state of knowledge, could not be effected by chemical means alone, but required a further filtration through land."

The systems which were submitted to trial at the Salford sewage works were the International, the Electrical, and the Aluminoferric, and the Barry systems. The borough engineer points out that in his opinion the main features which should influence the Corporation in their choice are—first, that the effluent or treated sewage which has to pass into the Ship Canal should be so purified that no nuisance will arise from it after decomposition, that the sludge produced should not exceed half the weight of the sludge produced by the lime process, that the efficacy of the process should be permanent, and that the working expenses and capital cost of the process should not be disproportionate to the result to be obtained. The sewage to be dealt with contains a large amount of manufacturing refuse from chemical and paper works, and Mr. Carter Bell has estimated that the bleaching powder and caustic drugs produced in the various paper works using the Irwell and the Roach must be something like 150 to 200 tons per week. About one-eighth part of the sewage treated at the works comes from the Pendleton sewers, and is richer in organic matter. Up to the present time the system of precipitation by lime, which has been found to give good results at Birmingham, Leeds, Bradford, and other large towns, has been the one adopted by the Salford Corporation; but the effluent resulting from the lime treatment is known to be subject to a process of secondary decomposition, which would unfit it for discharging into the confined waters of the Ship Canal, and the recent experiments were therefore entered upon with a view to discover some more efficacious method.

The International Water and Sewage Purification Company, Limited, undertook a series of experiments with their system, which is a filtering system, in use at Acton, Hendon, Tottenham, Swinton and Pendlebury, Royton, and other places, and has been very favourably reported on. Professor Frankland, who is perhaps the highest authority on such matters, stated in a report submitted to Major Tulloch, of the Local Government Board, that "no chemical process of purifying sewage had ever in his experience approached this in efficiency."

The system of the Electrical Purification Association, Limited, consists in passing an electrical current through the liquid sewage. No addition of chemicals is requisite, the necessary reagents being evolved from the sewage itself by electrolysis. It will be seen that the theoretical basis of the system is extremely simple, but its application necessarily involves a considerable outlay in channels for the sewage, electrodes, and dynamos. In the experiments at the Salford sewage works, which were designed to deal with 3,000 gallons of sewage per hour, the crude sewage was passed through a channel of brickwork 90ft. long and sufficiently large to contain the 364 plates of cast-iron which formed the electrodes. Each of these plates weighed about 2cwt. The sewage in its course along the narrow channel was subjected to the electric current passing between the electrodes, and the impurities were separated in the form of a flocculent scum, which floated on the surface. A period of quiescence was allowed in a tank set apart for the purpose, and the impurities then settled to the bottom, leaving the purified effluent to be withdrawn. The electric current was derived from a dynamo which, in the report of Mr. Giles, of Messrs. Mather and Platt, is described as of the Charlesworth and Hall type, with an output of 50 volts, 50 amperes, and was driven by a small inverted compound engine working at about 600 revolutions per minute, with 100lb. steam pressure. The current and E.M.F. were measured with instruments carefully tested with Messrs. Mather and Platt's instruments, and readings were registered hourly. In order to test the consumption of iron due to the decomposition of the iron plates, each plate was carefully weighed before being inserted in its place, and again washed, dried, and weighed at the completion of the experiments. The weight before commencing was 34 tons 8cwt. 2qr. 18¾lb., and at the conclusion they were found to have lost 1cwt. 1qr. 19⅝lb. As the daily flow of sewage is about 10 million gallons, the annual consumption of iron involved is shown to be something like 700 tons. The amount of sludge produced by the electrical system was smaller than by any of the other systems under consideration, and the quality of the effluent was excellent. In summing up his report on the chemical aspects of the two systems above named, Mr. Carter Bell says: "If the International or the Electrical Company will guarantee the Corporation of Salford to produce an effluent from the whole of the Salford sewage which shall equal the effluents they have produced during the last few months, then I think the Corporation will be justified in expending the large amount of money that would be involved in purifying the sewage."

The other system tested was the Aluminoferric system, using alum cake. The results were far from satisfactory from a chemical point of view; Mr. Carter Bell reporting that all the effluents were very unsightly from suspended matter, and also from being of a brown colour. As he could not distinguish by the appearance the effluents from the crude sewage, this was certainly not a system which he could recommend the Corporation to adopt.

ELECTRICAL STANDARDS COMMITTEE.

The following draft resolutions, with others, dealing with the practical measurement of power, whether developed by unvarying or alternating currents, will be submitted to the Electrical Standards Committee for discussion at their next meeting, which will take place on Friday, the 20th inst.

1. That it is desirable that new denominations of standards for the measurement of electricity should be made and approved by Her Majesty in Council as Board of Trade standards.

2. That the magnitudes of these standards should be determined with reference to the centimetre as unit of length, the gramme as unit of mass, and the second as unit of time, and that by the terms centimetre and gramme are meant the standards of those denominations deposited with the Board of Trade.

3. That the standard of electrical resistance should be denominated the ohm, and should have the value 1,000,000,000 in terms of the centimetre and second.

4. That the resistance offered to an unvarying electric current by a column of mercury of a constant cross-sectional area of one square millimetre, and of a length of 106·3 centimetres at the temperature of melting ice may be adopted as one ohm.

5. That the value of the standard of resistance constructed by a committee of the British Association for the Advancement of Science in the years 1863 and 1864, and known as the British Association unit, may be taken as ·9866 of the ohm.

6. That a material standard constructed in solid metal, and verified by comparison with the British Association unit, should be adopted as the Board of Trade standard ohm.

7. That for the purpose of replacing the standard, if lost, destroyed, or damaged, and for ordinary use, one or more copies should be constructed, which should be periodically compared with the standard ohm and with the British Association unit.

8. That the standard of electrical current should be denominated the ampere, and should have the value one-tenth (0·1) in terms of the centimetre, gramme, and second.

9. That an unvarying current which, when passed through a solution of nitrate of silver and water containing from 15 to 20 parts by weight of nitrate of silver in 100 parts of water, deposits silver at the rate of 0·001118 of a gramme per second, may be taken as a current of one ampere.

10. An alternating current of one ampere shall mean a current such that the square root of the time average of the square of its strength at each instant, in amperes, is unity.

11. That an instrument constructed on the principle of the balance in which, by the proper disposition of the conductors, forces of attraction and repulsion are produced which depend upon the amount of current passing, and are balanced by a known weight, should be adopted as the Board of Trade standard for the measurement of one ampere, whether the current be unvarying or alternating.

12. That the standard of electrical pressure should be denominated the volt, being the pressure which if steadily applied to a conductor whose resistance is one ohm, will produce a current of one ampere.

13. That the electrical pressure at a temperature of 62deg. F. between the poles or electrodes of the voltaic cell known as Clark's cell, constructed and used in accordance with the specification attached to these *Proceedings*, may be taken as not differing by more than — parts in 1,000 from a pressure of — volts.

CONTINUOUS-CURRENT TRANSMISSION AT CALAIS.

The railway company at Calais in lighting their stations had to solve the problem of lighting three stations at some distance from each other in such a manner as to be independent of each other, while at a minimum cost for plant and maintenance. Calais being the point of embarkation for Dover, the whole station has been organised in a manner different to other stations to expedite as much as possible the progress of passengers. The station comprises, in reality, three stations at the points of a triangle about the same distance from each other—nearly two miles. Calais town is the one in use for ordinary passengers to this town from inland; Calais pier is reserved for the direct traffic between France and England; and the third is the Calais goods station. It is evident that the town station has no need of the light after a certain hour at night. On the other hand, the pier station needs light at certain irregular intervals at the arrival and departure of boats, while the goods station, in which the work of shunting is carried on all night, requires a constant illumination.

The problem has been solved, according to an interesting article in the *Bulletin Internationale de l'Electricité*, by constructing a central station with transmission of power for the respective service of each of the stations. At first it was proposed to use alternate currents, but this was abandoned from a fear of accidents to the staff, and the scheme was definitely adopted of using high-tension direct currents for motors which transform into low-tension direct currents by the mains of second dynamos.

The lighting comprises 30 arcs and 320 incandescents at Calais town, 23 arcs and 221 incandescents at Calais pier, and 20 arcs and 150 incandescents at Calais goods station.

The central generating plant installed at Calais town station comprises two steam engines of 250 h.p. each, at 90 revolutions per minute, driving four dynamos (horizontal field magnet type), giving at 700 revolutions a current of 27 amperes at a pressure of 1,000 volts.

Each of the other stations is connected with a double set of overhead lines to guard against accident. The length of each line is about two miles, a total in all of about 24 miles for the double lines for the three stations. The section of the copper is 38 mm. square.

The pier and the goods stations, respectively, have two motors each of exactly the same type as the dynamos on the generating station. Each of these is coupled direct to two Manchester dynamos, giving 200 amperes at 70 volts, making four dynamos for lighting at each station.

The arc lamps are of three different systems—Cance, Pilsen, and Maquaire—and are run in parallel with 70 volts at the terminals of the machines, and 55 volts at the lamps. Besides this a battery of 160 accumulators, of a total capacity of 700 ampere-hours, are placed at Calais pier station. The two other stations are furnished with similar batteries.

It is thus seen that the independence of the three stations is complete. Any one of them needing light has only to start its motors, and when the dynamos have built up to full pressure, switch on the lamps.

This installation, which has been working since May, 1890, has experienced no accident whatever since starting.

NOTES ON THE ELECTRIC RAILWAY: HISTORICAL, STATISTICAL, AND TECHNICAL.*

BY FRANKLIN LEONARD POPE.

Every trade and profession has its well-worn stock of traditional anecdotes, handed down from a remote antiquity, which the veterans are accustomed to relate in hours of idleness for the amazement, or the amusement, as the case may be, of the youngsters.

The telegraphic service, in which 30 years ago I was an aspiring and ambitious youthful "plug," was no exception to the rule. You will pardon me if I recapitulate two of these ancient tales, which I tell as they were told to me, for the sake of the moral which they point.

One of these stories was to the effect that an inventive genius down East, which meant Boston or beyond, had once contrived a great improvement on the telegraph as we knew it, inasmuch as by its means the telegraph operators, or anyone else for that matter, could converse directly through the wire.

"A most magnificent invention," solemnly asseverated our chief operator, Jack Selden; "it was tried with perfect success between Boston and New York, but, sad to say, it had to be given up, because the New York operator's breath smelt so strongly of bad whisky." But in later days Alexander Graham Bell, of Boston, did actually show us how to speak through the whispering wire, and owing, let us charitably hope, to the permanent reformation of the objectionable habits of the New York operators, it did not this time "have to be given up."

The other story was about an unsophisticated old man, a shoemaker, who lived and had a little shop in Natick, between Worcester and Boston; for aught I know, he may have been the original "Natick cobbler." The only son of this old man was a soldier in our army in Mexico This was in 1848, when the telegraph was a new thing and a great mystery, and its frequent despatches, bringing the latest news from the seat of war, kept the community in a continual state of feverish anxiety, of which in later years we all came too well to know the full meaning. One day a letter came to the shoemaker from his son complaining of the condition of his boots, worn to shreds by long and hard marches, and wishing that he had a durable pair of the paternal manufacture. Struck with a happy thought, the good old man immediately constructed a pair of his very best No. 12 cowhides, affixing a tag to them inscribed with the proper address, tied the straps together, and hung the boots over the telegraph wire which passed his house. In the morning they were gone. A belated tramp had appropriated them, and with a certain sense of grim humour not unknown among these gentry, had hung his own dilapidated brogans in their place. "Look, Marthy," exclaimed the delighted cordwainer the next morning as he gazed out of his window in the dim light of dawn, "Johnny has got his new boots so quick, and has sent his old ones back by telegraph to be mended."

But to-day the improbable romance of the talking wire, and the imagined electrical transportation of the simple cobbler of Natick, have both become realities. The speaking telephone is found in every business office and in almost every home. Freight and passengers are hauled over elevated ways by electric power, and probably no one in this audience entertains a doubt that the day is close at hand when the electric transportation of passengers will be conducted at a rate of speed which most people now deem almost inconceivable.

Every consideration of common humanity, not to speak of public convenience and economy, unite to urge the speediest possible substitution of mechanical for horse power on our numerous street railways, and this is for many reasons especially to be desired in cities in which the most desirable residential neighbourhoods can be reached only by routes including long and comparatively steep ascending grades. It is but just to the street railway managers of the United States to say that these considerations have not been without effect.

It is only six years ago that an electric street railway was put in actual commercial service in the United States for the first time. This was in the city of Cleveland, O. To-day considerable more than one-third of the total street railway mileage of the United States is either operated by electric power or contracts have been entered into for the substitution of an electric equipment for that now in use, at the earliest possible moment.

At a meeting of the American Street Railway Association held in Washington only a little more than two years ago, almost the sole subject of discussion was the question of improved motive power for street railway service. Every manager and superintendent present realised that the demands of traffic were rapidly outgrowing the existing methods, and many of them had begun to look forward to the application of electric power as the only possible solution of the problem. As one delegate after another reported his experiences and observations in respect to electric traction, a member who had listened to it all with evident impatience arose and entered his solemn protest against all the new-fangled talk about electricity. He said that he had come there upon the assumption that it was a horse-railroad convention in order to get information about horses. He wanted to know how to shoe them, how to feed them, and how to work them to the best advantage; and as he continued to complain, it was evident that in more than one place in the assemblage his ideas met with a sympathetic response.

Less than four months ago the same association held its annual meeting at Buffalo, and in his opening address the president, Thomas Lowry, of Minneapolis, made the following significant remark:

"I am so thoroughly convinced that electricity is the coming power for street railways (except on very heavy grades, where the cable is best suited), and that it will prove so effective as a means of rapid transit for cities, that I believe that this is the last convention that will ever seriously consider horses for the operation of street railways."

Nor was this all. Many of you who are familiar with the fact that President Lowry, whose energy, ability, and foresight will never be questioned by anyone familiar with his career, threw away, in 1889, a brand new cable plant, which cost nearly half a million dollars, in order to replace it with electric motors.

Some of his associates undoubtedly entertained grave doubts of his sanity, but every new electric road brings a fresh tribute of approval to his enterprise and to his courage. Since he took that memorable action, electricity has changed the whole aspect, both scientific and commercial, of municipal transportation.

Few people have any conception of the enormous extent of city and suburban traffic in the cities of the United States. A few statistics are more impressive than pages of rhetoric.

The official returns show that during the year ending

---

* Paper read before the New York Electric Club, Jan. 22.

Sept. 30, 1889, the 110 street railways in the State of New York carried over 686,000,000 passengers, or 100 times the total population. In New York City alone the surface and the elevated roads carried together about 400,000,000. In Boston 100,000,000, and in Philadelphia 150,000,000 passengers were carried. In fact, statistics indicate that the street railways of the United States carry something like twice as many passengers as all the steam roads, and, moreover, it has also been found that the number of passengers increases from year to year in a much greater ratio than the population, which means, not only that more people ride, but that the same people ride more frequently each succeeding year.

The transportation of this enormous number of passengers—probably not less than four or five billions, taking the whole country together—with safety, comfort, speed, and economy, must be recognised as an undertaking of the most gigantic description. It is well worth our efforts to carefully consider the best means by which it can be accomplished. No work has ever been done by the inventor, the engineer or the electrician, of such immediate and direct benefit to the masses, as that which has to do with the subject under consideration.

Considered in a general sense, the electric car is a self-propelling vehicle, the actuating force of which is derived from an electric current, through the agency of an electric engine, or, as it is technically termed, a motor. We may conveniently consider the subject of electric railways by dividing them into three classes, which are distinguished from each other in the manner in which the current is supplied to the motor upon the car. These are :

1. The so-called overhead system, in which the electric current is supplied to the car through a wire suspended above the track.

2. The underground system, in which a supply conductor is placed in a conduit beneath the surface of the street, and the current is taken into the car by an arm projecting downward through a slot in the top of the conduit.

3. The storage battery system, in which the current is furnished by storage batteries (which are, in fact, a species of electrical reservoirs) placed underneath the seats of the car, and charged at the terminal station with a sufficient quantity of electricity for each trip.

While differing from each other in respect to the manner in which the current is supplied, certain essential principles are common to them all. In all electric cars the motor is composed of a stationary portion called the field magnet, and a moving portion called the armature. The electric current causes the armature to revolve, and the armatures being geared to the car axles move the car. The driver starts the car by establishing an electric connection between the motor and the electric conductor, overhead or underground, or the storage battery, as the case may be, stops the car by interrupting the electric connection, and reverses it by reversing the direction of the current which passes through the motor.

The time which I have allowed myself will not permit me to enter as fully as I should like into the history of the electric motor, but there are certain prominent epochs in its development which require a passing notice.

The discovery that it is possible to produce continuous mechanical motion by the agency of the electric current is due to an eminent English philosopher. It was made early on the morning of Dec. 25, 1821. For many years this discovery was regarded as nothing more than an interesting philosophical experiment, but the world is now awakening to some adequate conception of the magnificent possibilities of the humble gift which was slipped into its stocking on that Christmas morning, by one who had not long before jocosely described himself as "Michael Faraday, late bookbinder's apprentice, now turned philosopher."

In 1831 Joseph Henry, then Professor of Natural Philosophy in the Academy at Albany, N.Y., and afterwards the distinguished secretary of the Smithsonian Institution at Washington, in a letter to Prof. Silliman, of New Haven, said : "I have lately succeeded in producing motion by a little machine which I believe has never before been applied in mechanics, by magnetic attraction and repulsion." This was a crude and simple affair, but served sufficiently to illustrate the principle of such apparatus. Those who are interested to see it will find it carefully preserved in the cabinet of Princeton College.

Having thus demonstrated the possibility of constructing an electromagnetic engine, so far from giving way to the natural enthusiasm of the successful inventor, Henry proceeded, with that calm sobriety of judgment for which he was peculiarly distinguished, to forecast the future possibilities of the new motor. He was soon led to see that under the conditions of knowledge then existing the power could only be derived from the oxidation of zinc in a galvanic battery, and hence the heat energy required in the original smelting of the metal must represent at least an equal amount of power. Hence his conclusion that the fuel required for that purpose might with better advantage be employed directly in performing the required work.

While feeling thus assured that electricity could not hope to compete with, much less to supersede, steam as a primary source of power, Henry, nevertheless, did not hesitate to predict that the electric motor was destined in the future to occupy an extensive field of usefulness, particularly in applications in which absolute theoretical economy was subordinate to more important considerations.

Time has shown that Henry's conception of the legitimate field of the electric motor was prophetically accurate, but his views failed to impress themselves upon the minds of his contemporaries. In the expectation that electricity would soon be the universal motive power, the problem of its utilisation was during the next 10 years attacked with great zeal by a considerable number of inventors. The earliest as well as the most meritorious of these was a Green Mountain village blacksmith by the name of Thomas Davenport. Some time since, while preparing a lecture to be delivered before the Board of Trade, in Springfield, Mass., I accidentally learned that this inventor had constructed a model of an electric railway in Springfield more than 50 years ago, undoubtedly the very first appearance of the electric railway in the history of the world. The work of this pioneer electrician, and even his very name, being almost unknown to the present generation of labourers in this fertile field, my curiosity and interest were sufficiently excited to lead me to undertake an investigation, with a view to rescue whatever knowledge of his work had escaped the ravages of time. In this it has been my fortune to meet with an unexpected degree of success. The record of his career shows that Thomas Davenport was a man of no ordinary merit, pursuing the occupation of a village blacksmith in Brandon, Vt., at that time an obscure country town, far removed from all main lines of travel and transportation, and long before the day of railroads, but as Prof. Eaton justly said of him, "possessing one of those minds which cannot be confined to the limits of a blacksmith's shop, nor any other shop less than the canopy of heaven," he had no sooner been shown as a curiosity the effect of Prof. Henry's electromagnet in lifting a blacksmith's anvil by the magnetic power generated by three small battery cells than he was seized with the idea that electromagnetism might be applied to the propulsion of all kinds of machinery, and, in fact, might be made a universal motive power. From that moment his whole life was devoted solely to the realisation of this conception.

(To be continued).

THE DEVELOPMENT OF THE ELECTROMOTOR.

The electromotor has ceased to be a curiosity and has taken its place as a piece of ordinary everyday machinery. It is being applied to such a variety of uses that it is difficult to prophesy to what extent its use may not grow in the near future. It furnishes us, without doubt, with one of the most economical means of transmitting energy, and this, combined with its portability and reliability, ensures its adoption in numberless directions.

Already the "boom" for "electric traction," or the propulsion of tram and railway cars by its means, has commenced, and one has only to listen to ordinary conversation to hear of new ways in which it is proposed to utilise it. In electric cranes, electrically wound clocks, electrically worked pumps, the transmission of energy over long distances, the distribution and economical subdivision of energy in factories, and in many other ways electric motors find everyday application.

This being the case, it will not be inopportune at the present time for us to pass in review the chief stages of its development from the rotating wheel of 1830 to its present form, to note how our ideas as to its mode of action have gradually formed, and to explain in a popular form the various modifications motors have to undergo in order to enable them to be economically employed under widely differing conditions.

The electromotor dates from 1830, for it was in that year that Michael Faraday, our illustrious fellow-countryman, discovered that we could generate electric currents by rotating a closed conductor, placed at right angles to a magnet, in a magnetic field.

Faraday did not follow this discovery up, but left others to tread in the path he had indicated. Sturgeon soon after brought out his simple rotating wheel, of which a description is given in many text-books on electro-dynamics, and Prof. Henry introduced, in America, his method of obtaining powerful electromagnets by winding many coils of wire round a soft-iron core. Barlow, Page, Davidson, and Ritchie are but a few of those pioneers who during the next few years invented and perfected various means of producing rotation by means of the reactions taking place between a wire carrying a current of electricity and a magnet. These are interesting from a historical point of view, but a detailed description of them does not enter within the scope of this paper.

Some of these early motors were of considerable size, for we read that in 1839 Prof. Jacobi, of St. Petersburg, who paid a great deal of attention to this subject, constructed one large enough to propel a boat holding 12 persons at a speed of 2½ miles an hour on the River Neva, using as the means of obtaining his current 64 large Grove cells. Motors were also constructed by other experimenters large enough to work at 10 h.p., but the cost of producing the current to drive them from primary batteries, and the lack of knowledge as to the principles underlying motor action, sufficiently explains why so many of these wonders were relegated to the lumber-room.

The fact which, for a time, was a sore stumbling block was this—the motor started all right, but as the speed increased the current passing through it decreased, therefore, it was urged, the resistance of the armature must increase. This was certainly puzzling, and although men thought it a deathblow to their hopes of an economical machine, when properly understood it proved to be one of its chief merits.

It was Jacobi who found the clue to this mystery, and even he did not fully appreciate the meaning of his explanation, while others for a long time did not accept it. He noticed that when the motor was working it acted as a generator on its own account, and produced an E.M.F. acting in opposition to that driving it, and consequently decreasing the current. He enunciated the following law to which, when speaking of the work obtainable from a motor, we shall have occasion to refer:

"The mechanical work given out by a motor is a maximum when the motor is geared to run at such a speed that the current is reduced to half the strength it would have if the motor were stopped."

This showed that a motor did most work when half the current was used in warming up the machine, and when accepted, as it ultimately was, it led to the general though not universal opinion that a motor could not attain a greater efficiency than 50 per cent.; electricians did not generally grasp the fact that although a motor might do most work when working under these conditions, yet it might not do it in the most economical manner.

Meanwhile, the modern dynamo machine had been gradually evolved; in 1856, the introduction of Siemens's shuttle-wound armature had greatly improved the magneto machine, and in 1863 the now historic Pacinotti machine was made by a professor of that name at Pisa, in Italy. For some years the description of this machine, published in an Italian magazine, was unnoticed, and in 1867 the self-exciting principle appears to have been rediscovered by Wheatstone, Varley, and Siemens, all working independently of each other. The two ways of winding field magnets "in series" and "in shunt" with the armature were found out, and when, in 1870, Gramme added to the general stock of knowledge his method of making and winding ring armatures and the Von Alteneck way of winding drum armatures was introduced, our modern dynamo was complete.

These machines were found to work as motors, and Siemens soon afterwards showed that Jacobi's law did not relate to "maximum efficiency," but only to "maximum activity," or rate of doing work, for he exhibited one of his dynamos working as a motor at an efficiency of 67 per cent.; an impossibility if Jacobi's law was to be received as popularly understood.

He stated that we obtained maximum efficiency when the relation of useful work done by the motor to the total amount of energy taken from the current bears the same ratio as the back or counter E.M.F. generated by the motor to the E.M.F. at the terminals of the motor. This is now usually called "Siemens's law of maximum efficiency," and when speaking of this in the subject we shall have occasion to recur to it.

Electromotor science was now well under way; it was seen that the production of a counter E.M.F. by the machine itself was no drawback, but only a fresh confirmation of the great principle of the conservation of energy. The motor as we now know it was an accomplished fact, and the next thing to find out was how best to design it, and how to modify the design to suit varying conditions of supply and varying requirements of work.

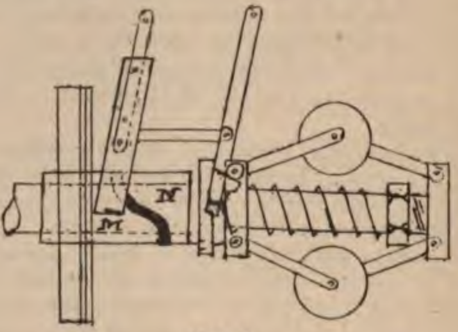

Fig. 1.

The first attempt at a complete scientific explanation of motor action was made by Profs. Ayrton and Perry, who, in March, 1883, read a paper on "Electromotors and their Government," before the Society of Telegraph Engineers. This proved to be a very valuable contribution to electromotor science, for after reviewing previously known facts, they went on to state their own views on the matter. Although through lack of time no discussion took place then, yet since, both in the Press and on the platform, their conclusions have been strongly opposed; and by noting the arguments used by both parties, we may learn a great deal. It will be well to find out what these varied views are.

Commencing by saying that the chief advantages of motors were four, Profs. Ayrton and Perry went on to enumerate them—viz.:

1. Portability.
2. Small weight per horse-power of work done.
3. Ability to be used at a distance from the prime mover.
4. That they work to better advantage when running fast.

Then, after reminding their hearers of the two ways of winding field magnet circuits—viz., "in series" or "in shunt" with the armature—they went on to describe various methods of governing the speed at which motors run under varying loads and varying conditions of supply.

Dealing first with supply at constant potential and varying load, they say: "A motor can be governed to run at the same speed, whatever work it may be doing, in one or other of two distinct ways. First, the power may be cut off in proportion as the work is cut off; or, second, a brake may be employed to replace the useful load removed."

The device then in use for governing by the first mentioned method was called the "spasmodic governor," and after reading the description of it, those will fully appreciate it who have had any experience with mercury spark.

It consisted of a cup containing mercury, into the centre of which a wire was led, thus completing the electrical circuit. This cup rotated with the armature, and at low speeds the circuit continued closed. When it ran fast, however, owing to the fact that the surface of the mercury assumed a circular form, being of course depressed in the centre, the wire ceased to dip into the mercury, the circuit was broken, the current interrupted, and the motor slowed down. The wire again dips into the mercury and the motor commences to run a little faster; by this means a rough kind of government is carried on.

They proposed, as an improvement upon this, the "periodic governor," of which a drawing is given above. Instead of shutting off all the power when too much was supplied, it only cut off a portion of it during a part of each revolution, the time during which the smaller supply was given being governed by the work. This was done in the following manner. On a continuation of the armature spindle two circular pieces of metal, M N, shaped as in the diagram, insulated from the spindle, and connected with each other through a resistance, were placed. Upon this a brush rests, and the position of this brush is regulated by the speed by means of the governor balls. As the motor runs faster the governor balls diverge, and the brush is brought for a longer period upon the part where less current is supplied, and the motor, consequently, is slowed down, only again to be accelerated when, by the governor balls collapsing, the brush is moved upon the other portion of the collector for a longer time, and more current is given to the motor. Governors of this class all suffer from the defect of excessive sparking, a fault which practical men will say altogether disqualifies them from general adoption. Partly for this reason, and partly, also, because at the best only jerky and imperfect regulation is possible by these ways, the writers recommended government by electrical means on their second method, and suggested the following arrangements:

1. The armature of a small series-wound motor was connected with the armature spindle of the motor. The external circuit of the small dynamo is so arranged that its critical speed is the same as the required constant speed of the motor. When the motor runs below its proper speed but little current is generated by the small dynamo, and consequently not much energy being absorbed from the motor, it acts as a weak brake. When the speed, however, gets above the required limit, much more current is generated by the dynamo, much more energy taken from the motor, and immediately it acts as a powerful brake and tries to pull the motor speed down.

2. They proposed using a small magneto machine in conjunction with the motor, the current generated by the small dynamo being led round the motor magnets in such a direction as to weaken them. The armature of the magneto machine is mounted on the same spindle as the motor armature. The resistance of the circuit is constant, therefore the current will increase in the same ratio as the E.M.F., which is in its turn dependent upon the speed. Therefore when the motor "races," the action of the magneto machine is to cause it to slow down; if it slows down, the field magnets become stronger and the speed is increased. Regulation by these means was not perfect, and these combinations of two machines soon grew obsolete.

Profs. Ayrton and Perry, in explaining these methods of government, compared the action of the small dynamo to that of a brake which acted in opposition to the motor, and balanced any inequalities of external work.

Various modifications of these ways were proposed to render them suitable for constant current circuits, but as these ways are not at the present time in use, it does not fall inside the scope of this paper to describe them.

Passing on from the subject of the government of motors, they went on to investigate into the proper relative proportions of armature and field magnet. From mathematical and theoretical considerations, they came to the conclusion that in a motor to obtain maximum output from a machine of a given weight, the armature should form 90 per cent. of the total weight and the field magnets 10 per cent., while for a dynamo the reverse held good—viz., 10 per cent. for armature and 90 per cent. for field magnets. We conclude from this that in their opinion at that time a good motor was a very different thing from a good dynamo, and we may prove this by the following two quotations from this part of their paper.

"We cannot lay too much stress on the importance of this fact, that a motor must work mainly by attractive force and not by repulsive force. The magnetic fields due to the field magnet and armature must help one another and not oppose one another, as is the case with a dynamo."

Further on they say:

"We have every reason to believe, therefore, that an investigation concerning these relative sizes in a motor made to any design, such as we can at present imagine, if soft iron is used in the field magnet, must have the result that the armature part ought to form a much greater part of the whole weight than the field magnet part, whereas in a dynamo machine it is the armature to which the very small weight must be given."

These quotations show clearly what was intended by the writers.

They exhibited at the same time their own motor, which they were then introducing, and which in appearance was very unlike our present types. The armature, which was the outside portion and fixed, was of the Pacinotti form, the field magnets to which the brushes were fastened looking like a Siemens shuttle-wound armature. The commutator was fixed, and the brush in rotating pressed successively against every part of it. The efficiency of a small one which weighed 37lb., and whose output was about one-fifth of a horse-power, was about 40 per cent. when running at 1,576 revolutions per minute.

Mr. Mordey has been very prominent in his opposition to Profs. Ayrton and Perry's views on this subject. Looking at a dynamo as a reversible machine, he approached the subject from a different standpoint. While the writers of the paper appeared to consider maximum output for minimum weight as the chief end to aim at in designing motors, Mr. Mordey and others argued that other considerations, such as minimum sparking and small amount of attention required in using them, were quite, if not more important. Instead of thinking of motors as working because of the magnetic attraction between the poles of the field magnets and the magnet poles in the armature core which are produced at the points in the armature where the current enters and leaves it, by the circulation of the armature current round the armature conductors, as Profs. Ayrton and Perry appeared to do, they preferred to consider the iron of the armature core as acting the part merely of a conductor for the magnetic energy of the field magnets, and the rotation of the armature to be due to the reactions caused by the presence of the armature conductor with a current flowing along it, in the magnetic field produced by the field magnets.

This way of looking at motor actions greatly simplifies them, and soon leads us to enquire whether further analogies may not be found between dynamos and motors, and if, after all, a good dynamo may not prove itself to be an equally good motor. Of course it would be unfair to compare a dynamo where only high efficiency had been considered in the design, with a motor where light weight had been made the chief aim. But when designed for similar conditions of work, ought not the best dynamo to prove the best motor? Mr. Mordey and his followers said "Yes," and the general agreement of practice to-day with their views proves to many minds their case. In dynamos the prevailing idea has been to keep the magnetic field as powerful as possible in comparison with the armature, and so to reduce as much as possible the variations of lead and the difficulties of sparking. We find that if we work on similar lines with motors we obtain similarly satisfactory results.

In the *Philosophical Magazine* for January, 1886, Mr. Mordey published the following results of some experiments he had made with a Victoria dynamo, at the works of the Anglo-American Brush Corporation. If we have a shunt-wound dynamo, with a very low armature resistance, and drive it at a constant speed, we find that the terminal difference of potential remains nearly constant during a long range of output. Mr. Mordey, to prove the converse of this, took a low resistance armature shunt-wound Victoria dynamo and supplied it with current at constant potential, and obtained the following results :

Speed.	Current.	Diff. pot. at terminals of motor.	Horse-power taken from motor.
975 rev.	36·3 amp.	140 v.	1·8
965 ,,	66·5 ,,	,,	6·6
948 ,,	97·1 ,,	,,	12·87
945 ,,	130·8 ,,	,,	16·3

The difference in speed with loads varying from 1·8 to 16·3 h.p. is 3 per cent.

Speed.	Current.	Diff. pot. at terminals of motor.	Horse-power taken from motor.
680 rev.	29 amp.	100 v.	1
677 ,,	61·4 ,,	,,	4·8
675 ,,	102 ,,	,,	9·14
660 ,,	123 ,,	,,	11·7

Here, again, the maximum variation of speed does not exceed 3 per cent.

This proved conclusively that for all practical purposes, when constant-potential circuits are used, a shunt-wound motor having a very low armature resistance, and consequently one in which the armature would be small compared with the field magnets, was the most suitable arrangement wherewith to obtain approximately constant speed for varying loads.

Meanwhile the practice of motor manufacturers was tending towards the same ends. Profs. Ayrton and Perry's design had become obsolete, and types gradually approaching nearer and nearer to our present dynamo forms were forthcoming.

The Griscom, a small American motor, was introduced into this country with the object of popularising the use of motors worked from primary batteries for domestic purposes, but it did not appear to meet with striking success. In this the armature was of the Siemens shuttle-wound type, and the field magnets of the shape known as the double-horseshoe form.

The De Meritens, Reckenzaun, and Immisch motors also made their appearance. Of these the Immisch was one which had certainly come to stay. In this machine the armature is a little larger in proportion to the field magnets than is usually the case with a dynamo, but the magnetic effects of the field magnets so overpowers that of the armature that usually the makers send them out with their brushholders fixed, considering no adjustment to be necessary. As now made, these motors still more nearly resemble dynamos, and because of their good mechanical construction, and the careful attention shown to electrical details, they have won for themselves a commendable reputation.

Messrs. Elwell-Parker, Mr. Reckenzaun, and others who were at work utilising the motor for tramcar propulsion, used as little iron as possible in their field magnets, but of as good quality as obtainable; in fact, in many of our present tramcar motors the magnetic effects due to the field magnet so overpower those due to the armature, that the brushes are fixed once at right angles to the magnet poles, and are not moved even when the direction of rotation of the armature is altered.

In the United States about this time the introduction of electrically-propelled tramcars went on apace, and among the many pioneers in this field Mr. Sprague occupies a prominent position. In October, 1886, he published in the American technical journals a description of his now well-known system of electric traction. In his motor, by using the very best iron in his field magnets, he was able to keep them powerful relatively to the armature. Apparently ignorant of Profs. Ayrton and Perry's differential mode of field magnet winding, and of Prof. S. P. Thompson's work as embodied in his "Dynamo Electric Machinery," published in 1884, he claimed to have discovered the facts :

1. That a shunt-wound motor runs faster if its magnetic field is weakened by inserting resistance into its field magnet circuit.

2. That by differentially winding the field magnets of a motor you may obtain perfect speed regulation for varying loads. Although he fully appreciated this result of differential winding, he appears to have considered as its chief advantage for tramcar work, the fact that he was able by weakening his magnetic field so to distort it that the magnetic effect of the increased armature current was neutralised, and adjustment of brushes for varying loads avoided.

That a shunt-wound motor runs faster when its field magnets are weakened, though at first sight paradoxical, is really what we might expect. Upon what does the "torque," or turning moment, of a motor depend? We find that it depends upon two things, the strength of the magnetic field and the amount of current passing along the armature conductor, and that it may be expressed as the product of these two terms suitably expressed. Although weakening the field magnet may lessen one of these factors—the strength of the magnetic field—yet at the same time it increases the other to a greater degree, for the magnetic field being weaker, a lower counter E.M.F. is generated, more current passes through the armature, and the product of the two, which is the expression for the "torque," is greater, consequently the motor runs faster.

With reference to the second claim, it was pointed out a month or two later by Prof. S. P. Thompson that this was in reality only an application of Ayrton and Perry's theory, and that he had so regarded it, and therefore that what was called Sprague's law of winding—viz., "that the number of turns in the shunt coil of the field magnet circuit must bear the same ratio to the number in the series coil as the resistance of the shunt coil and the armature"—was known previously. This drew from Mr. Sprague the challenge that both he and Prof. Thompson should make a motor on principles known prior to 1881, and that these should be tested by some impartial electrician. The challenge, however, was not accepted, and in April, 1888, Mr. Sprague published a lengthy reply, in which he further tried to substantiate his claim.

A feature of novelty in his method of motor regulation, and one that greatly increased its utility, was his proposal when starting the motor to reverse the direction of the current in the series coil, so that instead of acting differentially—*i.e.*, weakening the field magnet—it strengthened it, and so increased its starting power. When the motor was started, he altered the direction of the current in this coil so that it acted differentially. Previous to this time the fact that in all differentially-wound motors the large current used at starting was sufficient oftentimes to completely reverse the polarity of the field magnet, and so cause the motor to start backwards, had proved very troublesome.

Meanwhile—that is, during the summer and autumn of 1886—an interesting discussion, in which Mr. Mordey, Mr. Esson, Profs. Ayrton and Perry, and some others, had taken part, had been carried on in the technical journals, in which the vexed question how best to design a motor had been fully discussed. Mr. Mordey and Mr. Esson, among others, were strongly in favour of powerful magnets, relatively weak armatures, and small amount of lead ; while Profs. Ayrton and Perry still maintained their old position, and endeavoured, though in a slightly modified form, to enforce their views. Again last spring, during the discussion at the Institution of Electrical Engineers on the two papers—Mr. Swinburne's on "The Theory of Armature Reactions in Dynamos," and Mr. Esson's "Some Points in Dynamo and Motor Design"—the question came to the front. Mr. Swinburne said : "A motor is nothing but a dynamo running the other way, as a dynamo is a practically reversible machine"; while Mr. Esson was quite as sure that the armature should not be the preponderating portion. Prof. Ayrton gave the results of some experiments he had had made, details of which will be found in the *Journal* of the Institution (Vol. XIX., Part 85, p. 180), and among other things, mentioned that Mr. Snell had told him that Messrs. Immisch put 10 per cent. more iron into the field magnets of their machines when manufactured as dynamos, than when as motors of the same size. Mr. Mordey and Mr. Swinburne replied, and the long controversy has ended by the general adoption of Mr. Mordey's views.

At the meeting of the British Association in Birmingham in 1886, Mr. Mordey read a short paper "On an Electric Motor Phenomenon," which, as it brings to notice a peculiarity of these machines, may fitly be mentioned here. He was testing a 30-h.p. series-wound Brush motor, constructed to work with a current of 20 amperes. He found, on connecting it up and starting the generator, that it only ran slowly, and would not do much work. Wishing to find out what was wrong he pulled out one of the connections from the terminals, when the motor stopped suddenly and then commenced to run backwards rather faster than it did before, gradually, however, slowing down until it came to rest. On examination he found that the series winding of the field magnets had by mistake been connected "in shunt" with the armature. Hence, the resistance of the field magnet circuit being very small, most of the current had gone round them, very little through the armature, and the "torque," or turning moment, had been small.

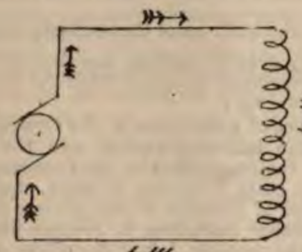

FIG. 2.

While the motor was rotating it was, of course, developing a counter E.M.F., small in this case because it was running slow, but when the circuit was broken this was able to send an appreciable current, in the reverse direction through the armature, but the same way round the field magnets, Figs. 2 and 3, because the resistance of the field magnet circuit was so small. Under these conditions the motor tried to start in the opposite direction, but was opposed at first by the inertia of the moving armature, which it quickly neutralised, and the motor stopped. This sudden stoppage of the current induces a momentary current in the same direction, which, under the peculiar conditions here present, is sufficient to so strengthen the field magnets that the armature is started again in the reverse direction to that in which it was originally running. These conditions are present in all shunt-wound motors, but the high resistance of the shunt circuit prevents, as a rule, the results above mentioned occurring.

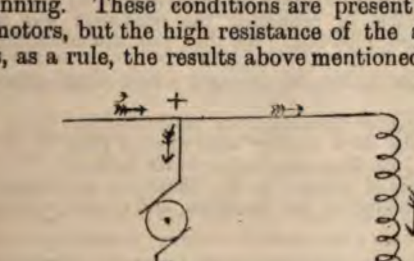

FIG. 3.

Having thus reviewed some of the chief facts connected with motors, dealing with them from an historical point of view, it would now be well to summarise our results and add anything else which might help us towards getting a clear perception of motor action.

There are two ways of winding the field magnets of motors, putting them either "in series" or "in shunt" with the armature.

Series-wound motors are extremely useful in cases where great starting power is required. Owing to the fact that when starting the magnets are fully excited and the armature current is also a maximum, the torque is greater than under any other conditions. They are, however, very sensitive to changes in load, and this renders them unsuitable for use when steady running is required.

If we wish to reverse the direction of rotation of a series-wound motor, we must remember that simply reversing the current through the machine will not do it, although we may alter in this way its polarity. We must only alter the direction of the current through either the armature or field magnet part.

Shunt-wound motors have very little torque or starting power. It is sometimes said they have none. An ideal one would not have any, as in such a motor the field magnets would be made of such perfectly soft iron that they retain no permanent magnetism. The resistance of the armature being *nil*, all the current would circulate round it, the magnets would be left unmagnetised, and no torque would be produced. In practice, however, these conditions do not hold good. We have both a small quantity of armature resistance and permanent magnetism, so that the motor will start, and the more readily the further it is from ideal perfection. If any practical difficulty arises from this source, do not switch the current through the armature until the field magnets have had time to magnetise.

The results quoted previously in this paper show how on constant-potential circuits motors are within a very small range self-regulating. This renders them extremely useful for practical purposes.

The efficiency of the motor depends upon a due appreciation of the laws of Jacobi and Siemens, both of which have been already stated and explained. Speaking generally, the faster we run our motor the more efficient it is; in fact, theory tells us that we get 100 per cent. when the counter E.M.F. generated by the motor is equal to the terminal E.M.F., but as in this case we should have no current, and consequently should be unable to do any work at all, we are obliged to be content with more practical figures. In recent machines, 94 and 95 per cent., when doing full work, have often been obtained. Those of us, therefore, who are looking forward to the time when motors will not only be generally used in factories and tramcars, but also for domestic purposes in every household, may well be satisfied with the machine we pride ourselves in having helped to bring to the state of perfection it at present occupies.

LEGAL INTELLIGENCE.

DICKINS v. THE METROPOLITAN ELECTRIC SUPPLY COMPANY, LIMITED.

This case came before the Master of the Rolls, and Lords Justices Bowen and Fry, in the Court of Appeal, on Wednesday. It was an application for a new trial. The action was brought (*vide E.E.*, Nov. 28, p. 486, vol. vi.) by Messrs. Dickins and Jones, drapers, of Regent-street, against the defendants, who were supplying them with current, for damages for suddenly cutting off the supply and plunging their premises into darkness. It appeared that in 1888 the plaintiffs were supplied with current by Mr. Pritchett under an agreement which, however, was not signed, but which purported to be terminable by six months' notice on either side. The defendants in March, 1889, took over the business of Pritchett, and wrote to the plaintiffs to inform them of their having done so, and the plaintiffs paid the quarterly payments due for the supply thenceforward to the defendants. In May the defendants wrote to the plaintiffs saying that they contemplated closing all the old agreements, and enclosing a form for a new agreement for the supply of electricity, which they requested the plaintiffs to fill up and return if they wished the supply to be continued. The plaintiffs put the agreement away, and inadvertently forgot to take any notice of the defendants' letter. The supply was continued as before, and the quarterly payments on the footing of the agreement with Pritchett were made by the plaintiffs to the defendants. On September 26, 1889, the defendants wrote saying that as they were turned out of the plaintiffs' parish they would not be able to supply the plaintiffs much longer, and advising the plaintiffs to make arrangements with some other electric supply company. On September 30 the defendants wrote again saying that they would continue to supply the plaintiffs until they were taken over by some other company. After that there were several complaints by the plaintiffs of decrease in the light, and on November 16 it failed altogether. Mr. Justice Stephen, before whom the case came, non-suited the plaintiffs, holding that there was no evidence of any contract to go to the jury, and that the defendants were only supplying the plaintiffs at will, and could at any moment stop the supply of electricity. The plaintiffs appealed.

Mr. Jelf, Q.C., and Mr. R. A. M'Call were for the appellants, and Mr. Lumley Smith, Q.C., and Mr. R. B. D. Acland were for the respondents.

The Court granted the application, and ordered a new trial of the action.

The **Master of the Rolls** said he thought the learned Judge had taken too strict a view of the matter. The question was whether there was any evidence which could go to the jury of any contract between the defendants and the plaintiffs for the supply of electricity. In his opinion there was such evidence, although he would not say that the jury must necessarily find that such a contract existed. There was evidence of an agreement between Pritchett and the plaintiffs which appear to have been adopted and acted upon by the defendants when they took over Pritchett's business. The case must therefore go for a new trial.

The **Lords Justices** concurred.

COMPANIES' MEETINGS.

CUBA SUBMARINE TELEGRAPH COMPANY.

Report of the Directors for the half-year ending 31st December, 1890:

The Directors beg to submit, duly audited, the balance-sheet and accounts for the half-year ended 31st December last. From these it will be seen that the gross receipts (including the balance brought from last account) amount to £21,325. 19s., and the gross expenditure (including the half of the annual payment on account of the 1881 cable) to £6,759. 11s. 3d., leaving a sum of £14,566. 7s. 9d. to the credit of revenue account. Of this the sum of £4,450. 13s. 10d. has been added to the reserve fund, which now stands at £79,000. The dividend on the preference shares will absorb £3,000, and leave £7,115. 13s. 11d., out of which the Directors recommend the payment of a dividend on the ordinary shares at the rate of 8 per cent. per annum, free of income tax, the balance, £715. 13s. 11d., being carried forward to the current half-year's account. The new cable between Batabano and Cienfuegos, referred to in paragraph 6 of the last report, was completely laid on the 19th inst., but will not be taken over from the contractors until it has undergone the tests required by the contract. The instalments already paid have been deducted from the reserve fund, which will also be charged with the balance of the contract price. The Cienfuegos-Santiago 1881 cable broke down on 21st August last, and the 1875 one, between the same points, became interrupted on the 13th inst. The latter is now being repaired by the Company's engineer, the vessel which laid the new Batabano cable having been hired for the purpose, and the restoration of communication is daily expected. When this is accomplished the vessel will proceed to repair the 1881 cable, the cost of which has to be borne by Messrs. Hooper, the contractors. A special meeting has been convened to remedy a defect in the articles of association which is deemed to be necessary in the interests of the shareholders. With regard to the suit against the Spanish Government, the necessary forms for bringing the case under the consideration of the Contencioso Court are not yet complete, but it is expected that within a short time the case will be ready for hearing. The usual comparative statement of traffic is submitted herewith.

The thirty-ninth ordinary general meeting of this Company was held at the offices, 58, Old Broad-street, E.C., on Wednesday, the 11th inst., at 12 noon, Mr. Thomas Greenwood, chairman, presiding.

The **Secretary** having read the notice convening the meeting,

The **Chairman** said that the report and the accounts had been in the hands of the shareholders for some days, and he apprehended they had made themselves sufficiently acquainted with them, so that it would not be necessary to have them read. [The report is given above.] The incidents in the history of the Company during the last six months had been few and not of sufficient importance to be brought to their notice that day. They had gone on the even tenour of their way. Their income had increased—*i.e.*, they had made an improvement on the corresponding period of £1,450, while their expenditure had been increased about £250, which had been mainly caused by an unusual outlay on land lines; they had therefore about £1,200 increase. There had been no breaks in their cables during the past half-year, and therefore no expenditure upon repairs. This had enabled them to carry forward a much larger sum to the reserve fund, £4,450 after paying dividends, and a balance of £715 to next half-year. That was a satisfactory state of affairs. Their new cable between Batabano and Cienfuegos had been very successfully laid, and their reports were satisfactory. When the tests had been made he had no doubt they would find it was in perfect condition, and the balance of the purchase money would have to be paid. So far as this had been paid it had been taken out of the reserve fund, and the remainder would further reduce that fund. Still, it would leave them a considerable amount of reserve. There had been a break in the cable which had been in the hands of the contractors. The 1881 cable ceased to speak in August last, but, inasmuch as the contractors were about to go out to lay the new cable, they (the Board) did not press them to repair the broken one immediately, because they would have the vessel ready to do the business. Their 1875 cable broke last month, and they had used that vessel for the purpose of repairing it. He was glad to say that repair had been completed, and their line was in full working order. The 1881 cable was now under repair at the cost of the contractors, and they were expecting to hear every day that it was in perfect working order, when all their lines would be in that condition. There was one other item he had to go into, and that was the action they had against the Spanish Government. Their case had been under the consideration of their lawyers there, and had been very carefully drawn. It had been translated, sent over here and considered by the Secretary and himself, and had gone back with certain alterations to Spain. It would come on for hearing soon. He thought they had a good case, but there was always the glorious uncertainty of the law to be reckoned with. However, when they got the intelligence they would make the shareholders acquainted with it. He thought he had touched upon all the items, but would be glad to give any further information. He moved that the report and accounts for the half-year ending December 31 last be received and adopted.

This was seconded by **Mr. Low**.

In reply to a shareholder, the **Chairman** said that the above-mentioned action was brought under the following circumstances. The Spanish Government were about to grant a concession to their (the Company's) rivals—a French company—with the object of giving them the right to lay cables on the north side of the island, parallel to the Cuba Company's, which were on the south side. They (the Board) contended that that was a direct violation of the concession to them, and before the concession to the French company was granted they had taken action in the courts with a view of preventing it being done.

Mr. Griffiths asked as to the local and through traffic on their lines; what were the probabilities of each; and as to external rivalry?

The **Chairman** said they had no knowledge whatever of any variation likely to take place between the present relative income from the local and through traffic, though they might hope for an improvement in both. A cable had been laid from Halifax to Bermuda, but he knew nothing of that being continued to the island of Cuba. He then put the resolution, which was carried unanimously; as also was a resolution declaring dividends of 10 per cent. per annum on the preference and 8 per cent. on the ordinary shares.

This concluded the business of the ordinary meeting.

An extraordinary general meeting was then held to consider the following special resolution proposed from the chair and seconded by another Director—viz.:

"That the articles of association of the Company be altered by the addition of the following article, and the same is hereby adopted as one of the regulations of the Company:

"No person, not being a retiring Director, shall be eligible for election to the office of Director at any general meeting, unless he or some other member intending to propose him has, at least 21 clear days before the meeting, left at the offices of the Company a notice in writing under his hand, signifying his candidature for the office, or the intention of such member to propose him."

This, the **Chairman** explained, was moved in the interests of the shareholders, and in order that they might have notice of any change which any of them might desire to make in this direction. They had not got their full complement of Directors. They had only four out of the nine they could have. Four were quite sufficient for the work, and to increase the number would not benefit the Company, whilst increased fees would have to be paid. He then moved the above resolution, which was seconded by a **Director**.

Mr. Cochrane moved an amendment to the effect that that meeting considered any alteration in the articles of association undesirable and unnecessary.

This was seconded by **Mr. Griffiths**.

In putting it to the meeting, the **Chairman** remarked that they had gone on for 20 years with these articles, but they had got into days of competition, and they did not want to have any persons on that Board who might have interests in a rival company. No single member of that Board at that time had any interest in any other company which was antagonistic to that Company. Their only object in proposing the resolution was to protect the shareholders' interests. He then put the amendment, which was lost.

Mr. Cochrane thereupon proposed a further amendment, which was also lost.

And after further discussion the resolution put from the chair was carried, the days having been altered from 21 to 14, by 12 votes to three, the Directors voting in its favour.

A cordial vote of thanks to the Chairman was moved by **Mr. Cochrane**, seconded by **Mr. Griffiths**, and carried unanimously.

PORTRUSH ELECTRIC TRAMWAY COMPANY.

The annual meeting of the shareholders was held on February 2, at the offices of the Company at Portrush. The following Directors were present: Dr. Traill, F.T.C.D., chairman; Mr. C. M'D. Stuart and Mr. Wm. A. Traill, C.E.; Mr. Danl. Fall, jun., secretary and manager.

On the motion of **Mr. Stuart**, seconded by **Mr. Henry**, the seal of the Company was affixed to the register of shareholders.

The report of the Directors was then submitted, from which the following is taken: Your Directors beg to submit for the approval of the shareholders their annual report to December 31, 1890, which completes the eighth year since the line was opened for traffic. Your Directors are glad to be able to report another large increase in the passenger traffic in the year, the first-class passengers having increased to 8,943 from 7,847 last year, and 6,970 in 1888; and the third-class passengers having increased to 73,859 from 56,822 last year, and 48,370 in 1888—the total for the year being 82,802, with corresponding receipts amounting to £2,573. 19s. 5d., as against a total of 64,669, with receipts £2,038. 11s. 7d. in 1889, and a total of 55,340, with receipts £1,880. 6s. 10d. in 1888. The goods and mineral traffic amounted to 316 tons, compared with 323 tons in 1889, and the receipts have been respectively £41. 8s. 11d. and £37. 9s. 9d. The receipts for parcels and miscellaneous traffic have increased during the year from £43. 8s. to £77. 7s., so that the total receipts from the revenue account have been £2,698. 15s. 4d., as against a total of £2,114. 9s. 4d. in 1889. There has at the same time been a reduction on the expenditure side of the account, which shows a total of £1,687. 12s., as against £1,732. 10s. 9d. in 1889, and £1,929. 6s. 11d. in 1888. There is, consequently, a credit balance on the result of the year's working of £1,011. 3s. 4d., as against £381. 18s. 7d. in 1889, and £290. 5s. 5d. in 1888. This result has fulfilled the anticipations of the Directors stated in last year's report, and is traceable not only to the increase in the passenger traffic, but to the alteration made two years ago in the arrangements with regard to the goods traffic, which had previously been a constant source of loss to the revenue. It will be seen on an examination of the above figures that the ratio of expenses to receipts, which was 82 per cent. in 1889, has been reduced to 62 per cent. in the past year. The value of electricity as a locomotive power, when generated by water power, has been remarkably shown during the past year, owing to the great rise in the price of fuel for the steam engines. The expenses of the electrical working amounted to £272 for 20,884 miles run, or 3⅛d. per mile while steam power cost £707 for 11,286 miles run, or 15d. per mile. In 1889 the number of miles run by electrical and steam power respectively were 17,960 and 13,192, and the respective costs 6d. and 13½d. per mile, so that a change in the price of fuel has had a serious effect in the one case and none at all in the other. The cost of coke delivered in Portrush went up during the year from 26s. to 34s. 6d. per ton. The favourable state of the revenue account is, therefore, largely owing to the increased use of electricity as the motive power upon the line, with a corresponding reduction in the use of steam. The total mileage run shows an increase of 1,288 over the previous year, the respective numbers being 32,170 and 30,882. In dealing with the balance of £1,011. 3s. 4d. to credit of the revenue account, your Directors feel that they will have the approval of the shareholders in charging this balance with interest at 4 per cent. on £10,000 of £11,500 for the construction of the branch line to the Giant's Causeway. The net revenue account has, therefore, been charged with £400 interest on the above £10,000, and with £400 interest on the advance of £10,000 by the Board of Works. The rapid increase in Portrush from year to year is most favourable to the prospects of the Company, as that town provides a constant stream of visitors to the Giant's Causeway and the intervening coast scenery, while tourists from distant parts and the artisans from the manufacturing towns of Ulster will add a large contingent so long as the country generally is prosperous and agitation is crushed out by firm government. Your Directors have co-opted Mr. James Stewart Moore, of Ballydivity, as a director, in place of Mr. Atkinson, whose death they had to report at the last annual meeting. Sir William Thomson, F.R.S , and Dr. Traill retire by rotation, and are eligible for re-election.

Engineer's Report.—I have to report that the permanent way and works, electrical plant, engines, and rolling stock have been maintained in an efficient state during the past year. The anticipations in my last report have been verified. There has been a considerable reduction both in the working expenses and in the maintenance of the permanent way, although the total mileage has been greater than in any previous year, and I anticipate a still further reduction in the expenses in the ensuing year. The number of miles run by electricity has exceeded that of any year since the opening of the tramway—viz., 20,884 miles—worked at a cost of £271. 13s. 1d., or at 3⅛d. per mile, a lower rate per mile than has ever been attained before. The number of miles run by steam has been reduced to 11,286 miles, and they have been worked at a cost of £707. 7s. 5d., or at 1s. 3d. per mile run. From these figures, at once is apparent the enormous advantage of the electric motive power over the steam motive power, being about one-fifth the cost, mile for mile. Of the total 32,170 miles run, 28,166 miles—viz., 16,880 electric miles and 11,286 steam miles—were run during the six summer months, while only 4,004 miles, and these entirely by electricity, were run during the six winter months.

The report having been duly proposed and seconded, was passed.

Mr. Henry (shareholder) stated that he considered the report most satisfactory; that upon the year's working of the tramway there was an additional net gain of £629 above that of the preceding year, and that the total revenue gain of £1,011. 3s. 4d. was very gratifying, and that he looked forward to a prosperous future for the Company.

The usual vote of thanks being passed to the Directors, the meeting terminated.

COMPANIES' REPORTS.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY, LIMITED.

Directors: S. Wm. Silver, Esq. (chairman), Neil Bannatyne, Esq., Abraham Scott, Esq., Matthew Gray, Esq. (managing director), Robert Henderson, Esq., the Hon. Henry Marsham, A. Weston Jarvis, Esq., M.P.

Report of the Directors for the year ending December 31, 1890, to be presented at the twenty-seventh ordinary general meeting of the shareholders, to be held at the Cannon-street Hotel, London, on Thursday, February 19, 1891, at twelve o'clock:

The annexed accounts show the net profits for the past year to be £65,334. 11s. 2d. Adding £41,236. 6s. 8d. brought forward, and deducting £20,800 interim dividend paid in July, there remains a disposable balance of £85,770. 17s. 10d. The Directors have added £25,000 of this balance to the reserve fund (raising it to £300,000), and recommend the distribution of a dividend of 10s. per share, free of income tax, amounting to £20,800, making, with the interim dividend, a total payment for the year of 10 per cent., and leaving £39,970. 17s. 10d. to be carried forward. During the past year the Company has done a much larger general business than in any previous year, and a fair amount of cable work; but keen competition and increased cost of material continue to reduce the rate of profit. The works and machinery are maintained in a thoroughly efficient state. Mr. Bannatyne and Mr. Henderson, the directors retiring by rotation, offer themselves for re-election. Mr. Weise is re-eligible as auditor.

BALANCE-SHEET, 31ST DECEMBER, 1890.

NEW COMPANIES REGISTERED.

Shropshire Electric Light and Power Company, Limited.—Registered by Chester and Co., 36, Bedford-row, with a capital of £25,000 in £10 shares. Object: to carry on the business of an electric light and power company. The first subscribers are:

	Shares.
T. S. Eyton, Walford Hall, Shrewsbury	50
J. A. Bratton, Shrewsbury	20
J. B. Lloyd, Hetton Hall, Shrewsbury	20
R. Maddox, Belle Vue, Shrewsbury	20
J. Lea, Coton-hill, Shrewsbury	20
J. C. Porter, 3, Princes-street, Shrewsbury	20
H. Robinson, Bottaloy, Merioneth	20

There shall not be less than five nor more than seven Directors. The first are T. Slaney Eyton, J. A. Bratton, R. Maddox, H. Robinson, and J. A. Lea. Qualification, £200. Remuneration, £100 divisible.

Telegraph Construction and Maintenance Company.—The Directors, subject to the audit of the accounts, propose paying a dividend of 15 per cent., £1. 16s. per share, in addition to the 5 per cent. already paid, making 20 per cent. for the year 1890.

CITY NOTES.

City and South London Railway.—The receipts for last week were £702.

West Coast of America Telegraph Company.—The receipts for January were £3,925.

Brazilian Submarine Telegraph Company.—The receipts for the past week amounted to £5,956.

London Electric Lighting (Pioneer) Company.—Letters of allotment and regret have been posted.

Great Northern Telegraph Company.—The receipts for January were £20,800, against £19,600 in the same month of 1890.

Eastern Extension Telegraph Company.—The receipts for January amounted to £46,575, as against £40,610 in the corresponding month of 1890.

Eastern Telegraph Company.—The traffic receipts for the month of January were £60,005, against £59,478 in the corresponding period of 1890.

Western Brazilian Submarine Telegraph Company.—The receipts for the past week, after deducting 17 per cent. payable to the London Platino-Brazilian Company, were £4,858.

Cuba Submarine Telegraph Company.—The receipts for January were £2,400, as compared with £3,176. The decrease is owing to an interruption during the latter half of the month.

Edison and Swan United Company.—The Directors have decided to pay an ad interim dividend for the half-year ending Dec. 31, 1890, at the rate of 7 per cent. per annum upon the A shares, to be distributed in accordance with the articles of association. It is intended to issue the dividend warrants on the 20th inst.

Bell's Asbestos Company.—The Directors have resolved, in view of the audited accounts to the 31st of December, 1890, to recommend to the shareholders at the general meeting to be held on the 23rd inst. the payment of a dividend of 5s. per share, which, with the interim dividend paid in July, makes a total distribution of 15 per cent. for the year. The amount to be carried forward is £1,973.

PROVISIONAL PATENTS, 1891.

FEBRUARY 2.

1844. **Arm or elbow rests for telephonic purposes.** Joseph Slater Lewis, The Swifts, Yardley, near Birmingham.

1905. **An improved method of and means for distributing electric currents.** Llewelyn Birchall Atkinson, 1, Queen Victoria-street, London.

FEBRUARY 3.

1908. **Improvements in electrical switches.** David Maxwell, 87, St. Vincent-street, Glasgow.

1912. **An improved galvanometer or instrument employed for measuring, indicating, or detecting electric currents.** Joseph Slater Lewis, The Swifts, Yardley, near Birmingham.

1913. **An improved electric bell.** Joseph Slater Lewis, The Swifts, Yardley, near Birmingham.

1923. **Improvements in electrical switches.** Gustav Binswanger, 71, Queen Victoria-street, London.

1928. **Improvements in the method of and means for increasing the strength, volume or intensity of sound during transmission, applicable to telephones, microphones, phonographs, and other sound transmitting and emitting instruments and apparatus.** Charles Herbert Demuth, 1, St. James-square, Manchester.

1963. **Improvements in methods of and apparatus for electrically soldering cans and other sheet metal ware.** Mark Wesley Dewey, 45, Southampton-buildings, London. (Complete specification.)

1968. **Improvements in and relating to electric lamps or lighting apparatus.** Henry Harris Lake, 45, Southampton-buildings, London. (Frederick Victor Maquaire, France.)

1969. **Improvements in electrical signalling apparatus.** Henry Harris Lake, 45, Southampton-buildings, London. (Samuel Jason Burrell, United States.) (Complete specification.)

1987. **Improvements in electric lamps.** Alexander Melville Clark, 53, Chancery-lane, London. (James W. Easton, United States.) (Complete specification.)

FEBRUARY 4.

1994. **An electric light lamp shade.** Georgina Belt, Parliament-mansions, Victoria-street, London.

2009. **Electric thief and fire-alarm** Emanuel Berg, Link-strasse 29, Berlin.

2033. **Improvements in dynamo-electric machines.** William Lowrie and Robert Hammond, 433, Strand, London.

2040. **Improvements in switches for secondary batteries or accumulators.** Hermann Müller, 45, Southampton-buildings, London.

2045. **Electrical ore stamping and pulverising apparatus.** Richard Richardson Hutchinson, 11, Furnival-street, London.

2046. **Improvements in and relating to electrically propelled vehicles especially adapted for high rates of speed.** Richard Richardson Hutchinson, 11, Furnival-street, London.

(the

2061. **Improvements in electric lamp holders.** William Phillips Thompson, 6, Lord-street, Liverpool. (Joseph Benjamin Moore, United States.) (Complete specification.)

2067. **Improvements in electrical transformers.** Casper Baur and Wilhelm Dieselhorst, 28, Southampton-buildings, London.

2081. **Improvements in or relating to multiple circuit telegraphy.** Charles Adolph Gisborne, 77, Chancery-lane, London. (David Herbert Keeley, Canada.)

FEBRUARY 5.

2115. **Improvements in or connected with metallic gauze brushes employed in dynamo-electric machines.** Joseph Dean and Charles Jubb, Commercial-street, Halifax.

2152. **Improvements in electric switches.** James Cowan Woodburn, 96, Buchanan-street, Glasgow.

2155. **Improvements in armatures for dynamo-electric machines.** John Nebel, 28, Southampton-buildings, London.

FEBRUARY 6.

2180. **Improved means or appliance for fixing or driving staples or like devices, especially applicable to electric fittings.** George Thomas Mackley, 17, Southampton-buildings, London. (Carl Mackley, Germany.)

2199. **Improvements in automatic electric switches** Charles Walter Cox, Frederick Robinson, and William Henry Gritton, 6, Lord-street, Liverpool.

2200. **Improvements in or relating to electromotors.** Edward Attenborough, 323, High Holborn, London.

2201. **Improvements in laying and insulating underground mains for carrying electricity.** James Ernest Spagnoletti, 2, Great George-street, Westminster, London.

2219. **Improvements in electric arc lamps.** Emily Eliza Lever, 77, Chancery-lane, London.

2221. **Improvements in and relating to machinery for covering telegraph and telephone cables and wires with lead or other metallic compounds, also applicable for the manufacture of metal pipes and the like.** George Edward and Thomas Edward, 96, Buchanan-street, Glasgow.

2225. **Improvements relating to motors for electric railways.** J. B. Berlier, 45, Southampton-buildings, London.

FEBRUARY 7.

2289. **Electrical block signalling apparatus for single line railways.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, London. (Siemens and Halske, Germany.)

2293. **An improved cut-out fuse.** William Wilson Horn, 151, Strand, London. (George Herbert Whittingham, United States.)

2297. **A method of and apparatus for prolonging the life of the carbons in electric arc lamps.** Charles Walter Hazeltine, Norfolk House, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1883, Sec. 103, 9th July, 1890, being date of application in United States.) (Complete specification.)

NOTES.

Extension at Vienna.—The central station in Kaunitzgasse, Vienna, is to be extended, to comply with the increasing demands of customers.

Pacific Cable Rates.—The Eastern Telegraph Company will reduce their rate in 15 days after the Australian Government have accepted the conditions proposed.

Lost Children.—The latest telephone scheme is the organisation of a "lost child" telephone service, which in some towns has, it appears, given good proofs of usefulness.

Overhead Wires. — The London County Council General Powers Bill and the Overhead Wires Bill have been postponed till to-day, with a view to modification in some of the provisions of the measures.

Honolulu Cable.—The Naval Appropriation Bill, as amended last week by the United States Senate, appropriates a sum of 25,000dols. for soundings for a cable between San Francisco and Honolulu.

Eisenach.—The Allgemeine Company of Berlin, which has undertaken the establishment of an electric central station for Eisenach, has invited applications for capital for a third of the 300,000 marks, the estimated first cost for the plant.

Electrotechnics in Germany. — In the technical college at Darmstadt there were in 1890, out of 339 students, 97 electrical students against 48 architects, 46 engineers, 67 builders, 54 chemists, and 25 mathematicians and naturalists.

Cannes.—The Société d'Eclairage Electrique de Cannes has been formed in Lyons with a capital of 1,100,000f., divided into 2,200 shares of 500f. each. The object of the company is to supply electric light and power in Cannes and neighbourhood.

Edison Company.—It is stated that there is good reason to believe that the Vanderbilts have bought a large interest in the Edison General Electric Company, and rumour states the purchase at from 10,000 to 15,000 shares. The capital stock of the company is 13,000,000dols.

Ipswich.—At their last meeting, and after considerable discussion, the Town Council rescinded that part of their previous resolution which refused assent to the Ipswich Electricity Supply Company. Mr. A. Cattermole gave notice that at the next meeting he would move to rescind the rescinding resolution.

Nuremberg.—The Allgemeine Company are erecting a central station at Schnilling for the purpose of lighting the villages around Nuremberg. In each of these a sub-station will be placed, to afford independence of the centres of distribution. The price will be 1d. per 100 watt-hours, with a 5 per cent. reduction above a certain quantity.

Walsall.—The General Purposes Committee of the Walsall Town Council at the last meeting reported that they recommended the employment of Mr. F. Brown, of the Walsall Electrical Company, to advise with the Electric Lighting Sub-Committee, it being incumbent upon the Council to light a certain area by electricity within two years.

Compensation.—An action brought, before Mr. Justice Lawrance, against the City and Southwark Subway Company by the executors of Mr. J. F. Lovering, to recover £3,083 award for damage by the defendant company, was not held to be good upon grounds of wrong description of the lawful possessor, and judgment was given for the defendants with costs.

Brighton Grand Hotel.—The ordinary general meeting of the Brighton Grand Hotel was held on Wednesday at the City Terminus Hotel. Mr. W. Sharp, in moving the adoption of the report, stated that they had themselves now established an installation of the electric light at a cost of £6,000. They anticipated a considerable saving under this heading in the future.

Aberdeen Infirmary and Asylum.—At the annual meeting of the Aberdeen Royal Infirmary and Lunatic Asylum Corporation held last week, under the presidency of Lord Provost Stewart, Mr. J. Dove Wilson, LL.D., spoke in favour of the introduction of electric lighting into the institution, mentioning the success which had attended its adoption in the Victoria Hospital, Glasgow.

Cheltenham Theatre.—A new theatre and opera house at Cheltenham is to be built, and the tenders of Messrs. Bradney and Co., Wolverhampton, are accepted. It should be worth the while of electrical engineers to see that the electric light is introduced and provided for at an early stage. The address of the architect is Mr. F. Matcham, 3, Great James-street, Bedford-row, W.C.

Society of Arts.—The second of the Cantor lectures on "The Electric Transmission of Power," by Gisbert Kapp," will take place on Monday, February 23, at 8 p.m. Syllabus of Lecture II.: Transmitting Live Power—Fundamental Principles—The Dynamo and Electromotor—Regulating Appliances—The Line—Best Section of Conductor—Cost of Plant and Working Expenses—Examples.

New South Wales.—On January 1, at Newcastle, New South Wales, the official installation of the electric light took place. The installation will cost £9,000, and the contractors work the system for a period of 12 months. There are 360 incandescent lamps and 22 arc lights. It was pointed out at the ceremony that Newcastle is the first city in Australia to be entirely lighted by electricity.

The Royal Naval Exhibition.—The work at the Royal Naval Exhibition is progressing. The water-basin, the "Victory," and the different buildings are being pushed on. Capt. Wilson, V.C., of Her Majesty's ship "Vernon," has sent up some most valuable suggestions relative to the working of electric models on the water-basin, which will add another interesting item to those already thought of.

Glasgow Tramways.—The Glasgow Tramway Company have lodged a petition in the House of Lords against the Glasgow Corporation Bill *re* tramways. They object as future competitors to additional powers being granted to the Corporation, and maintain that the application of electricity to tramways is yet in its infancy, while much experience is required before its application to Glasgow can be said to be expedient.

Canterbury.—The question of electric lighting came before the Canterbury City Council last week. The Brush Company's offer was considered, and the lighting of the cathedral was alluded to, it being understood than the Dean and Chapter thought the initial cost far too large. The motion to accept the Brush Company's offer was not seconded, and eventually a committee was appointed to consider the proposed provisional order.

Simple Tester.—A little handy tester for linesmen, a modification of a well-known experiment, has been designed thus: a penny block of indiarubber has two plates of brass fastened thereon on each side, a strip of zinc and a shilling can be slipped under between brass and the rubber, while from the plates two leading wires are taken. Tests of continuity can then be taken by connecting the wires to the circuit and touching the two metals with the tongue.

Leamington.—The resolution has been carried by the sub-committee of the Leamington Town Council to discontinue the contract for lighting certain public streets. It was stated that the illumination had tested to only 10·3 candles. In the matter of further electric lighting, they agreed to be under the advice of the clerk, who had instructions to obtain a provisional order for lighting the borough, and the committee would not interfere with his position in any way.

Royal Society of Edinburgh.—The sixth ordinary meeting of the session of the Royal Society of Edinburgh took place on Monday, Sheriff Forbes Irvine presiding. Prof. Cargill G. Knott sent a note on a recent paper by himself on the interaction of longitudinal and circular magnetisation in iron and nickel wires. Prof. Tait, who read the note, said it raised a curious question as to the extraordinary influence of a very slight twist in the wire upon the results obtained from it.

Vienna.—There are now four electrical companies competing with each other in Vienna. These are the lately formed Austrian General Electric Company and the International Electric Company, the Vienna Electric Company, and the International Air and Electric Company. The last named exploits the Popp system. The Vienna Municipal Council have granted a concession to the Popp Company for distribution by compressed air and electricity. The central station will be commenced shortly.

Patent Office.—Sir Michael Hicks-Beach in the House of Commons stated that the abridgments for the subjects of electricity, acids, alkalis, oxides and salts, and benzene and carbon derivatives have been published up to 1876; and as regarded the period between 1877 and 1883, the bulk of them have been made and are now in course of printing. The subject matter index for 1856 to 1883 is out of print, but it has been widely distributed. For the future, its place will be taken by indexes to abridgment classes.

The Jarman System.—A practical demonstration of the Jarman system of electric traction is intended to be undertaken shortly on one of the tramway company's lines at Clapham. The system is being promoted by the Electric Tramcar Syndicate, Limited, who have already acquired a depôt in High-street, Clapham. There are now ready for placing on the lines two cars which are self-contained or accumulator cars, similar in appearance to those running on the Barking line of the North Metropolitan Tramway Company.

Electric Light in the Holy Land.—A decided sensation has been caused in Jerusalem by the introduction of electric light into a new and flourishing flour mill lately started there. The building in which the light has been introduced is near to the supposed site of Calvary, and close to the Damascus Gate. It need hardly be said that the Arabs and Jews are much puzzled to account for a light in a lamp in which there is no oil, and up to the present time, while gazing with wonder, have been keeping at a respectful distance.

Peroxide of Lead.—To cover iron and steel with a layer of peroxide of lead, Mr. Haswell, of Vienna, plunges the objects to be coated in a bath composed as follows:

Nitrate of lead	·8
„ ammonia	2
Water	100

The objects are connected with the positive pole of a source of electricity giving ·2 to ·3 amperes of current. Mr. Haswell has patented this process, but we do not quite see its utility.

Sunderland.—A special meeting of the Sunderland Council was held on Monday for the purpose of passing a resolution to apply to the Board of Trade for a provisional order for the supply of electricity within the borough. Alderman Pecket, in the absence of the Mayor, presided. Alderman Bell, in moving the resolution, said the deposit of £50 to cover the cost of the order had been lodged, but, if there should be any opposition, the expenses would probably be larger. Alderman Wilson seconded the motion, which was carried unanimously.

Meresole's Dry Battery.—To make the composition in this battery, mix intimately in a dry state—carbon, three parts; graphite, one part; binoxide of manganese, three parts; slacked lime, one part; arsenious acid, one part; glucose or dextrine, one part. This mixture, when finely pulverised, is then commingled with a saturated solution of sal-ammoniac and sea-salt, strengthened by one-tenth of its volume with a solution of bichloride of mercury and an equal quantity of hydrochloric acid. When this has been thoroughly mixed, the paste can be placed in a cell and sealed.—*Bulletin International de L'Electricité.*

Glasgow Art Museum.—Mr. James Paton, curator of the Corporation Art Galleries, read a paper the other day giving a sketch scheme of the proposed Glasgow Art Museum, for which a site has been granted. In his remarks upon the light, it should be admitted, he said, at as low a level as possible, and he instanced the galleries of the "Sheepshanks Collection" at South Kensington as answering satisfactorily the requirements. The incandescent electric light afforded a means of illuminating a picture gallery practically free from every objection which could be urged against an artificial system of lighting.

South Kensington Subway. — In the House of Commons on Thursday last week, the Bill for the South Kensington and Paddington Subway was read a second time. Mr. Baumann stated that the Bill was one to construct a railway from Bishop's-road, Paddington, underneath Kensington Gardens to the Albert Hall. Mr. T H. Bolton moved that the committee consider the insertion of a clause to provide that a certain share or royalty after a fair interest had been earned should be set aside as compensation for underground rights, but after discussion and a statement on the law of the subsoil, the motion was by leave withdrawn.

A Useful Book.—We have received the eighteenth edition of Spon's "Architects and Builders' Price Book" (1891), by W. Young. Besides the usual information as to building materials, ironwork, plumbing, glazing, etc., we have this year a chapter devoted to electricity, in which the author gives complete specifications and estimates for lighting installations as carried out by him. These include a country house (isolated plant), a town house (supplied from a central station), and a London bank (isolated plant using gas engines). The book is published by Messrs. Spon, 125, Strand, and will be found of practical utility to electrical engineers.

City and South London Subway.—The siding accommodation of the South London electric railway has been found insufficient, and arrangements are now in progress for the construction of additional sidings at Stockwell. On the recommendation of the Board of Trade, a fourth engine and dynamo is to be added to the generating plant at Stockwell depot, and it is intended also to add two additional trains and four additional locomotives to the rolling-stock. As soon as these additions are complete, it will allow of a considerable accession to the number of trains run, and the opening of the line on Sundays, if thought desirable.

Gaseous Fire Extinguisher for Telephone Exchanges.—Fires at the back of telephone switchboards are not uncommon, and has become with the overhead wires for electric railways in America so great a source of trouble that an automatic fire extinguisher has been devised by Mr. J. J. O'Connell, electrician to the Chicago Telephone Company. The action of the extinguisher is based upon the fact that carbonic acid will extinguish fire and will not affect insulation. A tank is filled with a solution of soda in water, over which an open vial of sulphuric acid is suspended; the mixture when set off on occasion of an accident, forms carbonic acid and the pressure is utilised to play upon the flames.

Leeds.—A meeting of the members of the Parliamentary Committee of the Leeds Corporation was held last Friday, Alderman Harrison presiding, for the purpose of hearing the representatives of the electric lighting companies which have applied for powers to supply the borough with the light. These are the Electric Installation and Maintenance Company, the Yorkshire House-to-House Supply Company, Limited, and the National Electric Supply Company, Limited. The proposals submitted by the representatives of the companies were discussed at great length, and the meeting was adjourned. A meeting will subsequently be held in order to arrive at a decision as to which of the companies the committee will recommend to the Council to supply the light.

Electric Alarms for Colney Hatch.—The Asylum Sub-Committee of the London County Council report that the only existing electrical communication in the buildings at Colney Hatch (which cover an area of eight acres) is the electric fire alarm. This is not sufficient, and it is often necessary to communicate by other means, by messengers, with the medical and other officers, which involves delay. The cost of providing this additional electrical communication is estimated to be £400. They are of opinion that these works should be carried out, and therefore recommend that subject to an estimate being submitted to the Council by the Finance Committee as required by statute, that they should be authorised to provide electrical communication at Colney Hatch Asylum.

The Fire at Cardiff.—It having been suggested that the fire at the Marquis of Bute's recent mayoral banquet might be due to gas, and not to the electric light, Mr. W. H. Massey, of Twyford, engineer in the Queen's Household, was asked to report upon the matter. He finds that there was no gas burner within 15ft. of the point where the fire broke out, and that the accident was undoubtedly caused by electricity. One of the electric collar-holders became overheated by an arc at the inside terminals, and this set fire to the tissue paper decorations which improperly surrounded the fittings. The roof of the drill-hall in which the banquet was held has been slightly scorched in places, but the building itself has sustained no damage, although some valuable family paintings were destroyed.

Cardiff.—At the meeting of the Parliamentary Committee of the Cardiff Corporation, the town clerk, with reference to the Cardiff Electric Lighting Bill, read a communication from Mr. J. A. Corbett, on behalf of Lord Bute, the Bute Docks Company, and the Glamorganshire Canal Company, embodying certain amendments, which he asked the committee to insert in the electric lighting order. Alderman Carey remarked that the object of the amendments was simply for the protection of the Bute and canal company's property; and they were adopted. The town clerk stated that opposition to the electric lighting order also came from the Taff Vale Railway Company and the Cardiff Gas Company, but the latter body in its original objections practically admitted the necessity for the Bill being promoted by the Corporation.

Telegraphic Communication between Bradford and America.—In the course of another week or so Bradford will be placed in possession of a direct cable service with America. Premises on the ground floor of the Midland-buildings, Forster-square (near the General Post Office), have been taken for the purpose, and workmen are at present engaged in putting in the requisite appliances. This arrangement is due to the large number of cable messages, chiefly of a commercial character, which daily pass between Bradford and the United States. Recognising the probability of an increase of such messages, the Government, in conjunction with the Commercial Cable Company (the Mackay-Bennett cable), have decided to provide direct communication from Bradford, *viâ* Liverpool, to Valencia, in the South of Ireland, the cable station for the Mackay-Bennett cables.

Birmingham Town Hall.—The Estates Committee of the Birmingham City Council have had before them the question of certain improvements in the Town Hall. With reference to lighting, they report that the committee have come to the conclusion that while retaining the use of gas in the hall, provision should be made for a proper installation of electric light. They have had before them some estimates of the number of lamps required, and they propose to take the necessary steps for carrying the installation into effect, the disposition of light and designs for lamps, electroliers, etc., being submitted to Messrs. Cossins and Peacock, in conjunction with the firms employed to do the work. The probable cost of the foregoing is estimated by the committee as follows: Entrances and staircases, stairs and alterations to basement, additional staircases from orchestra, firemen's staircases, etc., £3,767; heating and ventilation, £1,000; electric lighting, £1,200; total, £5,967.

Electric Plumbing.—A series of articles has been started in the *Plumber and Decorator* entitled "Electric Plumbing" by "Volt," to give an elementary insight into electric fitting. The author strenuously disclaims any idea of instigating the plumber to attempt to become an "electric engineer," or any intention of endeavouring to instruct him how to become one, but thinks that many country plumbers will be thankful for plain, practical instructions in electric bell fitting, and sufficient information *re* electric lighting to enable them, at least, to step into the gap where there has been a breakdown, and do a little ordinary repairing. A plumber can make a good soldered joint, and with some knowledge of electrical principles it is thought might become a good electric wireman. The tendency of the time lies in this direction, and the organ of the plumbing industry is no doubt well advised to induce its readers to turn their attention to electric light—always of course under the proper superintendence of a properly qualified electrical engineer.

Glasgow Lighting.—Before the Glasgow Police Commissioners on Monday, Mr. Gray mentioned that the Watching and Lighting Committee had directed the inspector of lighting to make enquiry as to the towns in which the electric light was used, and to report. He explained that they were not desirous of doing anything which would interfere with the interests of the Gas Committee. Mr. Ure, the convener of the Gas Committee, approved of their action, and explained that all that was wanted was to learn what was being done elsewhere, as to the lighting of streets with electricity, particularly in England. If it were found that the streets could be more efficiently lighted by electricity than by gas, the Gas Committee would not stand in the way. The committee would be glad to get all the information they could. Mr. Primrose said it was understood that in the metropolis electric lighting companies were having districts allocated to them. Proceedings in regard to electric lighting were being taken in many places, conspicuously in Leeds. The committee desired to know the merits of the various systems.

The London Library.—Both by its traditions and its popularity, the London Library in St. James's-square is virtually a public institution, and its committee is therefore properly subject to public criticism. The *Pall Mall Gazette* criticises it in a friendly manner, and wants to know why the committee of the London Library has not yet adopted the electric light. The mains of one of the lighting companies run past the door, and an institution that devotes nearly £1,000 a year to the wiping off of debt could easily spare a couple of hundred pounds for the installation and fittings. A library is a place where the electric light is more wanted than almost anywhere else, for books suffer horribly from gas. And the gas in the London Library is specially bad. Both readers and attendants complain of the bad light and the hot, stuffy atmosphere. Such an obvious improvement as the introduction of the electric light ought not to be delayed any longer. The extra expense incurred for lighting will soon be recouped to the funds of the library by the reduction of the binding bill, and by the increased efficiency of the staff.

Yarmouth.—The Electric Lighting Committee of the Yarmouth Town Council reported that they had considered the electric lighting provisional order obtained in the last session of Parliament by the Council, and a report was read showing that in nearly all the other towns in which provisional orders had been obtained nothing had been done further than to appoint committees to report upon the subject. It was resolved to recommend the Council to let the matter of lighting the main streets of the town with electricity stand over till July next, when the committee would again report on the subject. The town clerk and the borough surveyor were directed to supply the committee, in July next, with reports upon the electric lighting carried out in other towns to that date. The Council were recommended to pay the following charges in connection with the Great Yarmouth electric lighting provisional order: Sharpe and Co., parliamentary professional costs, £127. 16s. 6d.; costs out of pocket, £121. 8s. 2d.; (£249. 4s. 8d., less paid on account, £100) £149. 4s. 8d.; town clerk, professional costs and payments, £46. 18s. 4d. The report was adopted without discussion.

Welding Glass and Porcelain to Metals.—M. Cailletet has communicated to the Société de Physique a method of welding glass and porcelain with metals, which may prove extremely useful for instruments of research, or for any metallic fitting, such as taps, communicating tubes, conducting wires, etc., so as to avoid all leakage even under high pressures. The process of welding is of the simplest. A portion of the tube that is to be welded is covered with a very thin coat of platinum. To obtain this deposit, it is sufficient to paint, by the means of a small brush, the slightly warmed glass with completely neutral chloride of platinum, mixed with essential oil of camomile. The essence is made to evaporate slowly, and when the white and coloured vapours have ceased to be given off, the temperature is raised to dull red heat, and the platinum being reduced covers the glass tube with a brilliant metallic coating. Connecting the tube thus metallically coated to the negative pole of a battery of suitable energy, it is placed in a bath of sulphate of copper. A ring of copper is deposited upon the platinum, and strongly adheres thereto if the operation has been properly carried out.

London County Council.—The Highway Committee of the London County Council have considered a notice, dated Feb. 2, 1891, from the London Electric Supply Corporation, of intention to lay mains in Whitcomb-street, Spur-street, and Leicester-square (one plan). It is intended to lay the mains in 3in. cast-iron pipes, the mains themselves being lead-covered concentric cables. They see no objection to what is proposed, and recommend: "That the sanction of the Council be given to the works referred to in the notice, registered No. 158, dated Feb. 2, 1891, of the London Electric Supply Corporation, upon condition that the company do give two days' notice to the Council's chief engineer before commencing the works in any thoroughfare; that the mains be laid under the footways, and be kept 9in. below the under side of the paving, wherever it is found practicable to do so; and that where the mains cross the carriageways they be kept at the same depth below the concrete, or the road material, as the case may be." They have also considered a notice, dated 9th February, 1891, from the Kensington and Knightsbridge Electric Lighting Company of a proposed extension of mains in Ennismore-gardens (one plan). These works are of the ordinary character, and they recommend: "That the sanction of the Council be given to the works referred to in the notice."

Electro-Harmonic Society.—The next concert of the Electro-Harmonic Society will be a ladies' night, on Friday next, the 27th, at the St. James's Hall Restaurant (Banquet-room), Regent-street, at eight o'clock. Artistes: Miss Margaret Hoare, Miss Violet Robinson, Mr. Henry Guy, Mr. Bantock Pierpoint, Miss Frances Thomas, Mr. Alfred Izard; musical directors, Mr. T. E. Gatehouse and Mr. Alfred Izard. Programme.—Part I.: Trio, "Ti Prego" (Curschmann), Miss Hoare, Miss Robinson, and Mr. Henry Guy; song, "The lass that loves a sailor" (Dibdin), Mr. Bantock Pierpoint; song, "Bel Raggio" (Rossini), Miss Margaret Hoare; clarinet solo, Miss Frances Thomas; song, "The sailor's grave" (Sullivan), Mr. Henry Guy; lieder, "Geständniss," and "Du Fragst mich Täglich" (Helmund), Miss Violet Robinson; humorous selection. Part II.: Piano solo, "Ballade in G minor" (Chopin), Mr. Alfred Izard; song, "Where the Bee sucks" (Dr. Arne), Miss Margaret Hoare; new song, "Three Knights of old" (Boscovitz), Mr. Bantock Pierpoint; clarionet solo, Miss Frances Thomas; old French air, "Marguerite," Miss Violet Robinson; serenade, "Stars of the summer night" (Lassen), Mr. Henry Guy, humorous selection. With such a programme before them we hope every member who can do so will attend and afford the same pleasure to the ladies.

Shrewsbury.—At the Shrewsbury Town Council meeting the town clerk read a communication from the Shropshire Electric Light and Power Company, giving notice of their intention to apply for a provisional license to authorise them to supply electricity for public and private purposes within the borough, and asking the consent of the Council. Alderman Southam, in moving that the subject of electric lighting should be referred to a committee, said he did not like to see their good old town in any way lagging behind other towns. He thought the time had arrived when this question of electric public lighting would have to be taken up practically by all boroughs. Ludlow was, he noticed, about adopting it for the lighting of its streets, and he certainly should not like Shrewsbury to be behind Ludlow. He, therefore, would ask the Council to approve the reference of the question to a committee of the whole Council, in order that it might be fully considered. When such committee presented their report, the Council would be in a better position, with fuller information, to enter into a discussion of the question. He alluded to progress in Bradford and London, and proposed that the question of electric lighting in Shrewsbury should be referred to a committee of the whole Council to consider and report as early as possible to that Council with respect to it. Councillor Williams suggested the inclusion in the motion of the words "and the application of the Shropshire Electric Light and Power Company." Alderman Southam expressed his readiness to accept the suggestion and add it to his motion. The motion was amended accordingly, and agreed to. It was understood that the committee would meet within the next few days.

Preservation of Accumulators.—M. Gaston Roux, demonstrator at the Government Ecole de Physique et Chimie of Paris, has made a series of experiments to establish the conditions under which accumulators are best preserved when they remain a certain time without current being drawn therefrom. According to M. Roux, the most practical method is to charge them to saturation and then leave them to themselves. Trials were made with two Julien accumulators of 200 ampere-hours—part of a battery which had been serving for more than a year for experiments in the laboratory. The liquid of these accumulators is covered with a layer of paraffin wax, which was pierced with a small hole to permit thé gas produced in charging to escape. The containing cells are of glass, and are charged upon oil insulators. The solution, which contained 4 per cent. of sulphate of soda, had a density of 1·2 when the accumulators were charged to saturation. The two cells in question were charged on the 5th and then discharged on the 6th of August last, until their pressure was 1·8 volts. They furnished in this discharge 233 ampere-hours. On the 7th August they were again charged under the same conditions, and then left intact until 20th October. On this date they were discharged under the same conditions as on the 6th August, and 220 ampere-hours were taken out. As it must be admitted that the accumulators had received on the 5th and 7th the same quantity of electricity, it results that they only lost 13 ampere-hours—that is, 6 per cent.—during the 2½ months for which they were left to themselves. It may be said, as a general conclusion, that well-formed cells, well insulated, preserve their energy perfectly without being used, when the precaution is taken of charging them to saturation before being left to themselves.

Magnetic Rotation.—Before the Chemical Society a paper on "Magnetic Rotation" was read by Prof. W. Ostwald, of which the following is the abstract: "The magnetic rotation of organic compounds, according to Perkin, is an additive function of their composition and equal to the sum of the rotations of the components, but this is not the case with the rotation of inorganic compounds, which is usually found greater than that calculated on such an assumption. In the case of hydrogen chloride, for instance, the calculated value is about 2·18, and as a matter of fact the value obtained for hydrogen chloride dissolved in an organic solvent, isoamyl oxide, is 2·24, but when disolved in water the value found is from 4·05 to 4·42, increasing with the dilution. The author points out that these exceptional values are only obtained in the case of electrolytes, and that they must therefore be referred to a fundamental difference existing between the constitution of electrolytes and that of non-conductors. That such a difference exists has been already deduced from other considerations, and has led Arrhenius to the formulation of the theory of electrolytic dissociation. The author claims that the facts established with regard to magnetic rotation are in perfect accordance with this theory, and that any exceptional values in the magnetic rotations of electrolytes are due to the occurrence of electrolytic dissociation. In the discussion, Mr. Pickering said that in Prof. Ostwald's attempt to appropriate Dr. Perkin's results on the magnetic rotation of solutions of electrolytes in support of the dissociation theory, no attempt was made to explain what connection should exist between the magnetic rotation and the supposed dissociation into ions, but it was boldly stated that if, as in the case of hydrogen chloride, the magnetic rotation and dissociation both increased with dilution, the result proved the truth of the dissociation theory, while equal support to this latter theory was afforded if, as in the case of sulphuric acid, dilution diminished the rotation and increased the dissociation; and the most astonishing part of the argument appeared to be that the nearly double magnetic rotations obtained in some cases should be brought forward as a proof of dissociation, when the observations were made on solutions so strong that the dissociation theory represents them as containing hardly any dissociated substance at all. Surely the natural conclusion to draw from such a doubling when it occurs in the absence of dissociation would be that it could not be explained by dissociation.

Electrical Standardising Conversazione.—On Monday evening a *conversazione* was held by invitation of Mr. Hammond to view the Electrical Standardising, Testing, and Training Institution, at Faraday House, at the bottom of Charing Cross-road. The institution carries on the work of the old Hammond College, discontinued some years ago, but now considered necessary again by the rapid advance of electrical practice. Faraday House is a fine six-storeyed building, consisting of laboratories, workshops, lecture and class rooms, with engines and dynamos fitted in the basement. The laboratories are supplied with elaborate sets of testing instruments, including Sir William Thomson's ampere balances. The instruments, for a reasonable fee, will be placed at the disposal of experimenters. The work of training will be carried on by a competent staff, under the direction of Mr. H. E. Harrison, B.Sc. Some 500 visitors were received at the *conversazione* by Mr. and Mrs. Hammond, amongst those present being: Lord and Lady Castletown, Lord Russell, Sir Henry Mance, Sir Henry Cartwright, the Hon. Reginald Brougham, the Attorney-General, Prof. Kennedy, Prof. Riley, Prof. Forbes, Prof. Foxwell, Mr. W. H. Preece, Mr. Spagnoletti, Mr. Ferranti, Mr. Kapp, Mr. and Mrs. Langdon-Davies, Mr. and Mrs. Robert Fleming, Mr. F. H. Webb, Mr. William Lowrie, Mr. and Mrs. Powers, Mr. William O. Smith, and Dr. Robson Reece. The Earl of Crawford, chairman of the board of control of the institute, was prevented by indisposition from being present. Besides a very elaborate musical programme a large number of interesting electrical exhibits were provided. Visitors were much interested in seeing the phonopore, the invention of Mr. Langdon-Davies, in actual working order, sending duplex messages one in each direction along the wire already in use for Morse instruments, the minute induced currents being sufficient to vibrate a strained steel reed acting as relay switch for special telegraphic instruments, but not affecting the ordinary instruments. Messages in Morse letters were sent in triplicate and simultaneously for those desiring a practical test. Another interesting exhibit was Willis's electric ship-signalling apparatus, with Spratt's electric speed indicator, and Granville's new electric log, which dispenses with insulation on the tow line or the use of battery, all shown by Messrs. Elliott Bros. The Post Office sent an exhibition of telegraphic apparatus. The General Electric Company and the Electrical Supplies Company sent electric lighting fittings. Messrs. S. Z. de Ferranti and Co. and the House-to-House Electric Supply Company showed transformers, meters, and fittings of their respective systems.

UNDERGROUND MAINS.—IV.

THE CALLENDER SOLID SYSTEM.

(Continued from page 163.)

We now come to an interesting point, the connection of feeders, mains, and service lines.

In connecting the mains together, two different methods have to be considered: (1) those in which the joint is solid, permanent, and covered in with insulation in the same manner as the rest of the cables; and (2) those in which the connections of feeders to distributing mains and of those to house service mains are sometimes required to be altered or disconnected easily, either for change of load or for testing.

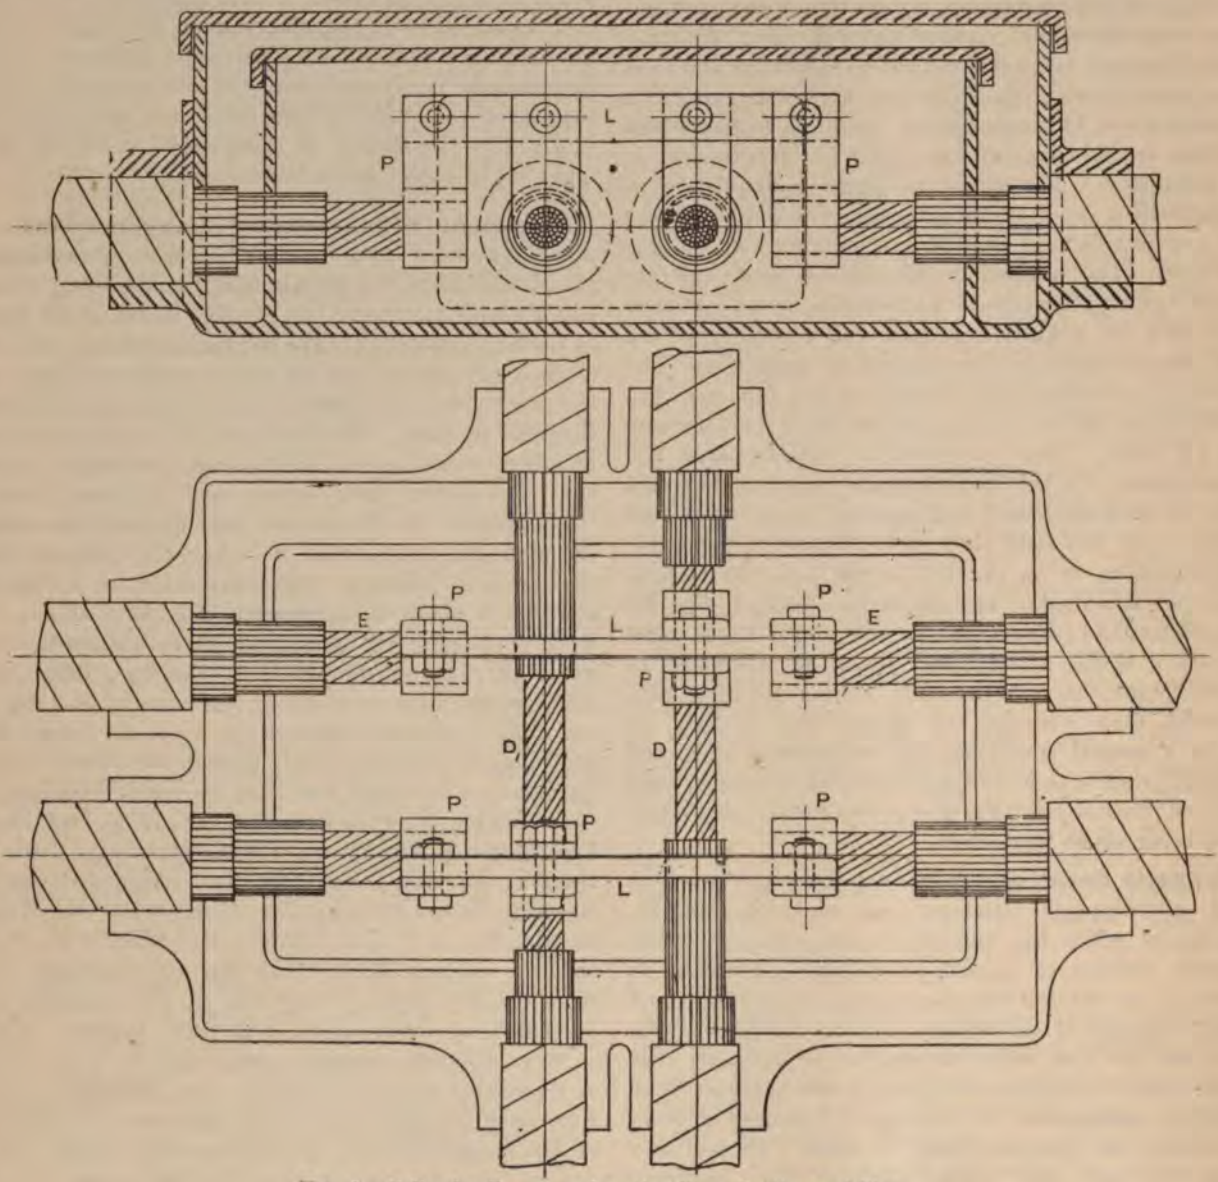

FIG. 5.—Callender Four-way Junction Box: Section and Plan.

We will first of all take the solid connection, premising, however, that it is now found desirable to use the second or changeable method in very many cases where the solidly insulated junction used to be employed.

In making the solid connection on the Callender system—as, for instance, where feeders are required to be permanently connected at a certain point to the distributors, or where two distributors are required to be connected in parallel to two other distributors at right angles—the method shown in detail in Fig. 5 is adopted. A double cast-iron box is prepared, cast in one piece, with an inner and an outer box, shown in plan and section, having their corresponding lids. This double box is pierced on all four sides with openings for the mains to be connected. The two larger mains are now cut to the requisite length to just pass a few inches into the inner box; and their copper ends, E E$_1$, are bared. A solid round copper socket, P, having a flat connecting piece projecting upwards, is securely sweated or soldered on each of these bared ends. The second pair of distributor cables, D D$_1$, are passed right through the junction-box without cutting, and a space of some inches is bared to the copper upon each of them—these spaces being not opposite to each other, but opposite to the mains to which they are to be connected. Similar copper pieces, P$_1$ P$_1$, are sweated to each of these bare places, one copper piece being fixed on the main D$_1$, on a line with the ends of the first main, E E, and the other piece being fixed on a line with the second main cable and projecting upwards to the same height as the copper pieces thereon.

All that has now to be done is to place solid lengths of copper bar, L L, across the mains, securely fastened by nuts and bolts—the positive main, E E, to the distributor D, passing over the other distributor within touching; and the negative to the negative distributor, D$_1$, passing over the positive without touching.

The cables and the connecting pieces are then insulated by semi-vulcanised material, and then protected by tape; the inner box is filled in with molten fine bitumen, and the cover placed on. The outer box is then similarly filled in with bitumen, thus forming a perfect protection from moisture getting into the joints in the inner box. The last lid is placed in its place, and the whole covered up with earth and finished off level to the road with the same paving as the roadway itself.

In certain cases these four-way boxes are left without the inner space being filled in with bitumen to allow junctions of house mains to be easily made. This type of box is, however, designed to be filled in solid and permanent, and, if accessible junction-boxes are required for the junction of house service mains or of a branch distributing main, a solid main fuse is used in a fuse-box with accessible manhole, as shown in Fig. 8 of our article on the Callender-Webber system on page 135, February 6. These accessible fuse-boxes are applicable to either system, solid or otherwise, and therefore need not be again described.

We now pass to the system of connecting mains and feeders in an ordinary central station network. In an extensive area of supply, the mains, both of feeders and distributors, will spread over a considerable area. Two things may happen to necessitate change in the connections. In the first place, a fault may be found, in which case tests would require to be made, and a certain length of cable might be required to be cut out of circuit; and, again, the demand for current may be altered in certain districts, and the points at which the feeders should feed into the distributors may require to be changed to some other point. It will be seen from this that a ready and rapid method of disconnecting mains, and of connecting up others in their place, is desirable on both grounds.

A simple yet ingenious method is used in the Callender system, shown in plan and section in Fig. 6, which illustrates a single-pole junction-box, having the ends of a network of four subsidiary mains connected to the feeding main. The principle of the arrangement is that of having, on the ends of each main, lugs of solid copper, which can be screwed to a copper "omnibus" bar, and so arranged that each, if unscrewed, can be swung round off the bar, and thus disconnected at once, without interfering with or touching any of the others.

The way in which this is carried out is easily seen in the illustration. A double cast-iron box similar to those already described for the simple four-way junction, has leading into it the ends of the main, M M_1. To each of these is sweated or soldered copper socket pieces, P, having a broad solid lug of copper, L, which is pierced for a bolt. The broad solid omnibus bar, O B, is bolted closely to these lugs, having a short piece of similar thick copper, S P, through which the full connection across is made. It can easily be seen that by unscrewing this swing-piece, S P, and swinging it back, the main, M_1, becomes disconnected.

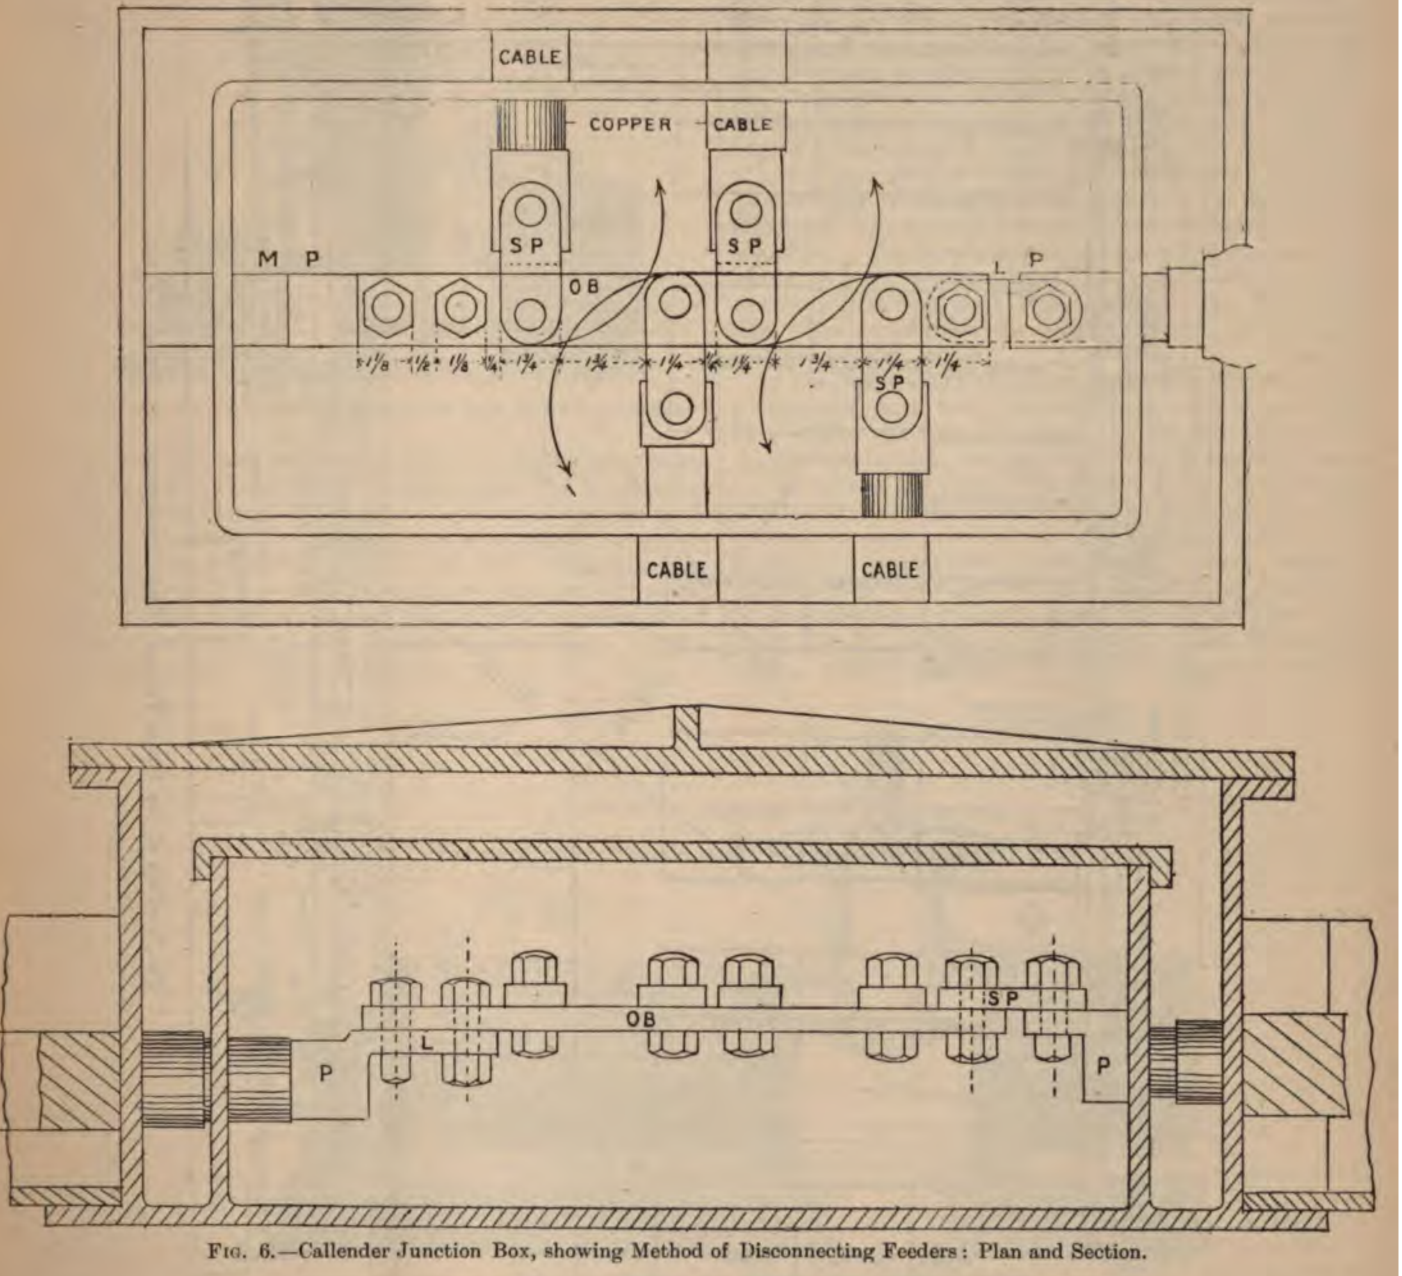

FIG. 6.—Callender Junction Box, showing Method of Disconnecting Feeders: Plan and Section.

In the same way the ends of the distributing mains are led into the junction-box, each having its end bared and a socket piece fastened thereto. Short swing-pieces, S P, are then bolted between the omnibus bar and these distributors. If occasion arises to alter the connection, or to cut off the supply from a certain district, all that is necessary to do is to unscrew one bolt and then move the swing-piece round clear of the bar The position of these pieces is arranged so that each can be swung round at its centre without the necessity for touching or removing any other connection.

(To be continued.)

THE POST OFFICE INSTALLATION.

(*Continued from page 158.*)

The Savings Bank branch of the General Post Office having been lighted by electric light for some considerable time with much success, and various country post offices having also received the benefit of this pure and cleanly light, it was only to be supposed that the General Post Office itself would be fitted in as perfect a manner as possible, so soon as arrangements could be made to instal the plant. Some time before Christmas last year the electric light was successfully started in the great sorting offices of St. Martin's-le-Grand, and both on account of the public nature of the institution, and also of the careful way in which the work has been carried out to guard against possible failure of light, the detailed description of the installation will be of interest to electrical engineers.

FIG. 9.—Plan of the Steam Piping. Ring Arrangement for Double Circuit.

The buildings known as the General Post Office, London, or more colloquially as St. Martin's-le-Grand, are, in reality, three separate buildings: two being at full work—the post office proper and the telegraph office—and one being in process of erection close to the others. They are known to the Post Office officials as G. P. O East, G. P. O. West, while the new building is to be the G. P. O. North. All these are to be lighted from one central station, whose position lies directly under the yard where the Post Office vans receive their sacks of letters to send throughout the country from the different railway stations. Some idea can be gained of the enormous industry of the Post Office when it is mentioned that an average of over 3,000,000 letters have to be examined, stamped, sorted, and packed up for delivery in a single day, and the long halls of this important central organisation of our busy metropolis contain thousands of sorting clerks busily occupied upon their work.

The installation comprises some 1,800 incandescent lamps of 16 c.p. and 60 Brockie-Pell arc lamps inside the buildings, with 16 Brockie-Pell arc lamps in the yard and outside. In addition, about 1,000 lamps are installed in the G. P. O. West, and more will be added during the course of the year.

We have given on the two previous weeks details of the switches and arrangements in the Post Office installation, and these will be referred to more fully in the course of the description.

The engine and dynamo room, as we have mentioned above, is in the cellars below the yard and a general view of this, showing the machinery, is given below. The plant consists at present of four sets of Willans and Robinson's G G high-speed engines coupled direct to Elwell-Parker 50-unit compound dynamos. The engines are of 80 i.h.p., and the dynamos supply current at 110 volts pressure. Two other engines of 200 i.h.p., coupled to similar 130-unit dynamos, will be added some time this year, and foundations are prepared for these additions.

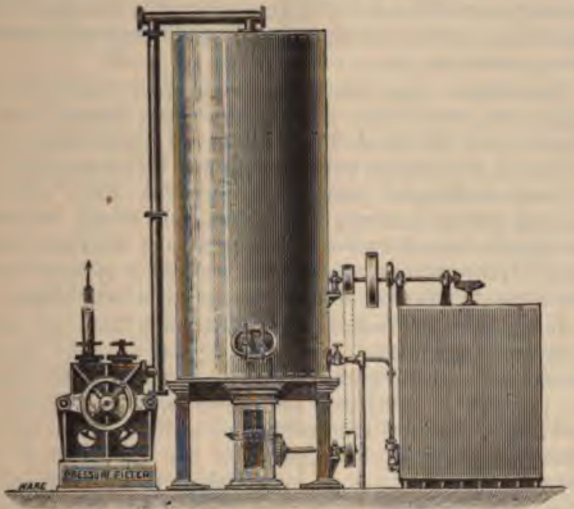

FIG. 10.—Porter-Clark Water Softener used at the Post Office

Each set is fitted with a Schaffer and Budenberg tachometer, and Dewrance and Co.'s patent sight-feed lubricators. The engines have all Willans and Robinson's latest improvements, amongst them being their steam separator, a chamber through which the steam passes, and into which the condensed water drains both from steam pipe and cylinders, thus providing dry steam, and also preventing possibility of rust when standing—rust in such engines being a more frequent cause of decay than wear.

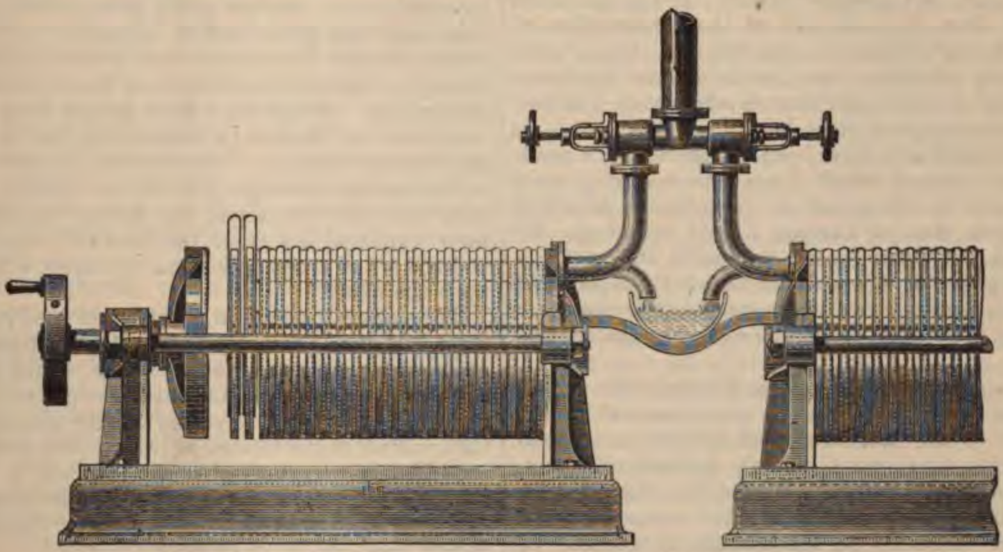

FIG. 11.—Pressure Filter of the Porter-Clark Water Softener.

The boiler-room is situated in a separate series of cellars close to the dynamo-room, and the arrangements have been very carefully thought out, both for security and facility of supply. In the first place, there is a complete ring circuit of steam piping, as shown in Fig. 9, giving a double path for the steam to any engine in case of accident to steam piping, and allowing any boiler or any engine to be cut off at will. The arrangement is made plain on the plan, which gives both the dimensions and the positions of all valves and connections. This scheme of steam piping makes quite a model system, and will be worthy of reference by those who are intending to put up similar important installations of electric plant.

The boilers are the Davey-Paxman locomotive multitubular type. There are three of these at present in use, and space is reserved for three others, making a battery of six in all when the whole Post Office plant is complete.

The question of incrustation in the boilers has received special attention, and a Porter-Clark water softener, made by Messrs. Porter Bros., 165, Queen Victoria-street, has been erected.

We are able to give a view of this water softener in Fig. 10, and a few words upon its action may be interesting. The incrustation which ensues from the use of hard water in boilers often—indeed, usually—becomes the thickness of ¼in., causing a waste of some 20 per cent. in fuel. If we assume that to evaporate 1,000 gallons of water per hour in clean boilers, one-eighth of its weight in good coal would suffice, we should have for 24 hours 108 tons ot water and 13½ tons of coal; and if with boilers encrusted with ¼in. of scale we lose 20 per cent., a very common case, only 86·4 tons of water would be evaporated instead of 108, and consequently 3·4 tons more of coal would be required. Taking, however, only two tons of coal extra, this, for 24,000 gallons per day, would result in a loss of 600 tons of coal a year, besides the deleterious results of hard firing. The remedy is to deprive the water of the minerals in solution before passing into the feed-water heater or into the boiler. The least costly reagent for this purpose in its action upon the bicarbonate of lime, usually found in hard waters, is lime used fresh from the kiln. The cost of this lime, allowing for all waste, does not exceed ¼d. per 1,000 gallons of water heated.

In the Porter-Clark apparatus we have in the first place a large cylindrical tank, into which the hard water is led by a supply pipe from the main. By the side of this is a smaller square tank, and the fresh lime is added to water in this tank in the proper proportion. The water supply sets in motion a small water motor, which in the first place pumps the lime mixture into the cylinder, and also, by means of a strap working vanes inside the tank, keeps the mixture well agitated. The water thus treated is forced, by the pressure of the main, along pipes to the filter. This filter, Fig. 11, consists of a number of iron frames and cloths, pressed together by means of a screw, and the water passing through these is run into a soft water tank, coming out beautifully clear and pure. From here it is taken as required to the feed-water heater and thence to the boilers. The sheets of the filter are unfastened and cleaned twice a week. Sufficient feed-water is kept in the reservoir to keep all four of the 80-h.p. engines going for five hours at full load. The feed-water tank has at present a three-way cock, to two of which are connected respectively a Worthington pump for filling the feed-water heater, and thence to the boiler, and an injector—thus giving double security of feed.

One difficulty that has had to be contended with is that the main drain of the street is 4ft. higher than the floor of the boiler-room. A large sump has therefore been built under the floor into which all waste water drains; from this it is lifted by an ejector to a large galvanised iron tank, fixed high up on the wall, and thence drains away into the main street drain.

NOTES ON THE ELECTRIC RAILWAY: HISTORICAL, STATISTICAL, AND TECHNICAL.*

BY FRANKLIN LEONARD POPE.

(Continued from page 169.)

It has been well said that "to rightly appreciate a discoverer we should not look at his work from our time; we should not judge of his work in the fulness of the light of present knowledge, but in the dim twilight which alone illuminated to him facts and laws then but imperfectly known. We must remember that at that date the steam engine was comparatively uneconomical, inefficient, and dangerous apparatus, and was regarded at best but a necessary evil; a thing to be tolerated and endured in the absence of available water power, but best dispensed with altogether wherever possible. At that date and for years afterward the annual catalogue of disasters by fire and explosion due to the use of steam was a lengthy and horrifying one. The report of a single year of the St. Louis Board of Trade gave a list of no less than 112 steamers which had been destroyed on the western rivers within the preceding 12 months by fire and explosion. Many people now living will remember the circumstance of over 60 persons being instantly killed by the bursting of a steam boiler in the heart of the business district of New York City. With such facts as these in mind it is easy to understand why the possibility of a new motor, compact, noiseless, manageable, free from all danger of fire and explosion, should be hailed with enthusiasm as a priceless boon to the industrial community. We must remember, too, that there existed at that time no data from which could be foreseen or determined, even with remote approximation, the relative economy of steam and galvanic power. It was not until 10 years later that the great law of the conservation of energy, and the correlation of the physical forces, now familiar to every schoolboy, was first formulated by Grove and Mayer and Joule; a law now so interwoven with our scientific conceptions that it is hardly possible for us to imagine that it could ever have been unknown. At a much later date than that of which I am now speaking, men whose names will be recognised as the foremost scientists of the time, such men as Lardner, Jacobi, and Joule did not hesitate to put upon record the belief that within a few years the power of steam would be wholly superseded by that of electromagnetism, and the *Scientific American* was publishing illustrated descriptions of perpetual-motion machines.

From the moment in which he first witnessed the experiment of lifting an anvil by Henry's electromagnet to the very last hour of his life, Davenport never once wavered in his belief that steam was ultimately destined to be supplanted by electromagnetism. Within six months from that time, with the assistance of another mechanic of the same town, he succeeded in constructing a machine by which he obtained continuous rotation by electromagnetic power. And it is worthy of remark that in this very first machine Davenport exhibited that unerring instinct of genius which ever distinguishes the true inventor, in that he grasped at once the fundamental conception of the combination of fixed and rotating electromagnets, the one reversible and the other non-reversible, which has characterised every commercially successful electric motor from the beginning until the present day. Time does not permit the rehearsal of the detailed story of his struggles, his failures, and his successes. During the six years between 1835 and 1841 he built more than 100 operative electric motors, scarcely any two of which were of the same design, and which varied in size from a small model up to an engine capable of driving a rotary printing press for 12 hours in succession. In December, 1835, he exhibited in Boston the model of an electric locomotive and circular railway which he had built in Springfield, and a similar, though more finely finished, model which was built by him the following year is still in existence in a good state of preservation. He published in 1840, now more than 50 years ago, in the city of New York, a weekly journal called the *Electro-Magnet and Mechanics' Intelligencer*, which was printed upon a press driven by an electromagnetic engine. Some of his motors, constructed as early as 1837 and 1838, were admirably designed, and in essentials, even to the shunt winding, differed but little from the present day.

Less than a year before his death, upon reading a newspaper account of the trial of the large engine built at Washington by Prof. Page under an appropriation from Congress, Davenport wrote a long and interesting letter to a local newspaper, congratulating Prof. Page upon his success, giving a concise but full account of his own work, and predicting with an earnestness born of entire conviction some of the most advanced and successful types in use at the ultimate triumph of electromagnetism over steam.

It has been the fashion to smile at such men as Davenport as enthusiasts. But may it not be that there is another side to the question? I do not forget that one of the greatest of American philosophers, Joseph Henry, has said: "The man of true genius never lives before his time. Though he may catch a glimpse of the coming light as it gilds the mountain top, long before it has reached the eyes of his contemporaries, and though he may hazard a prediction as to the future, he acts with the present." Viewed in this light, it may be said that Davenport did not live before his time. At least he acted with the present. It may be affirmed with entire truth that he gave every effort of his life to the development of his idea, and at last sunk into his grave, as he himself well realised, a victim of disappointed hopes. Yet, if Davenport was an enthusiast, so are we all enthusiasts as respects our anticipations of the realisation of the result which he predicted and for which he wrought unceasingly. Steam is nothing more than a convenient agency for the transmission of power, which derives its energy from heat and imparts it to mechanism. So soon as the great riddle of the day has been read—the production of electricity, as steam is produced, directly from heat—then, indeed, will the predicted triumph of electromagnetism over steam become an accomplished fact. Forty years have passed away since all that was mortal of Thomas Davenport was laid to rest beneath the Brandon elms, yet I think there are not many present in this audience to-night who do not cherish the expectation, if not the conviction, that before the half century has been completed the great problem will have been solved, and the era of a new industrial revolution will have dawned upon the world.

The electric locomotive constructed by Prof. George G. Page, which was tried by him on the Baltimore and Ohio Railroad in 1851, deserves a passing notice here. It was a noteworthy achievement, but developed no new principle, nor did it contribute anything to the ultimate solution of the problem of the electric railway. Many other promising experiments were made, but all resulted in failure, until the very name of electromagnetic motor became almost a synonym for "humbug." In discussing the question, Prof. Henry once said in his prophetic way:

"All attempts to substitute electricity or magnetism for coal power must be unsuccessful, since these powers tend to an equilibrium from which they can only be disturbed by the application of another power which is the equivalent of that which they can subsequently exhibit. They are, however, of great importance as intermediate agents in the application of the power of heat as derived from combustion. Science does not indicate in the slightest degree the possibility of the discovery of a new primary power comparable with that of combustion as exhibited in the burning of coal. We therefore do not hesitate to say that all declarations of the discovery of a new motive power which is to supersede the use of coal have their origin in ignorance or deception, and frequently in both."

I wish to call your particular attention to the remarks of

---

* Paper read before the New York Electric Club, Jan. 22.

Henry in the paragraph just quoted, that electricity and magnetism are of great importance as intermediate agents in the application of the power of heat.

In these words Henry accurately foretold the true place of the electric motor in the domain of industry. Not a little confusion of thought exist at the present time in reference to this very point. Every day we hear somebody speak of electricity as if it were a primary motive power.

It only requires a moment's consideration to see that such a view is wholly without scientific basis. Electricity is not a source of power. What then, I hear the laymen ask, is electricity? Those of us who are most familiar with it have but one answer to that question. We do not know; and for my own part, I very much doubt if we ever shall know. This much, however, is certain, electricity is a very convenient and very manageable agency, perhaps a peculiar form of matter, perhaps a peculiar form of energy, by which any quantity of mechanical power may be instantly transferred from a prime motor, such as a steam engine or water-wheel, to a secondary motor at a distance, which is employed to do the required work. It really performs exactly the same office as a belt or a line of shafting in a factory, which, however useful in conveying mechanical power from one point to another can, under no conceivable circumstances, be capable of originating it.

The electric motor, therefore, remained, for something like 40 years after its invention, an interesting but practically useless philosophical toy. It was like half of a pair of scissors—of no earthly use without the other half. The other thing that was needed was an organised machine which could convert large quantities of mechanical power into electricity. The discovery that it was possible to effect this conversion was also due to Faraday. With his usual sagacity he had suspected that it might be done, and undertook a series of experiments for the express purpose of finding out. On the second day he wrote to a friend: "I think I have got hold of a good thing, but cannot say; it may be a weed instead of a fish which, after all my labour, I may pull up." On the tenth day he pulled it up, and it was a fish; it was not a small fish either. He had made a discovery which, without injustice, may fairly be compared to Newton's immortal discovery of gravitation. But Faraday was a man who possessed pre-eminently the scientific mind. His delight in the pursuit and detection of the great truths of nature was so intense and so absorbing that he was never able to turn from them for the purpose of following up their practical application. "I have rather been desirous," he once wrote, "of discovering new facts and new relations dependent on magneto-induction, than of exalting the force of those already obtained, being sure that the latter would find their full development hereafter."

This was the beginning of the development of the magneto-electric generator. The next step is due to the genius of another American scientist and inventor, one whose name will occupy a far more prominent position in the annals of American science a century hence than it does to-day, Moses G. Farmer. He it was who, in 1867, in a letter to Henry Wilde, of Manchester, England, first described the principle of the modern dynamo-electric machine, and explained to him why the principle of its action was not like that of "a man lifting himself over the fence by the straps of his boots," as he humorously expressed it.

Almost at the same time similar machines were independently invented by Wheatstone and Varley in England, and Dr. Siemens in Berlin. The invention of the dynamo-electric machine gave a wonderful impetus to the investigation of every branch of electric science. The subject was taken up by scores of enthusiastic workers in all parts of the world; improvement succeeded improvement, until we have as a result the exquisitely-organised dynamo-electric machine of to-day, a machine which is admitted to have reached a perfection and efficiency which leave but the narrowest margin for further improvement.

The earliest field of usefulness of the dynamo machine was found in electric arc lighting, which has become in the United States an immense industry. One of the most effective of the early machines was designed by Gramme, of Paris, in 1872, and a number of them were shown by him at an industrial exhibition at Vienna in the following year.

Here occurred one of those extraordinarily fortunate incidents, which again and again have played such a prominent part in the history of industrial progress. In making the electrical connections to one of these machines not yet belted to the engine shaft a careless workman attached to it by mistake a pair of wires which were already connected with another dynamo machine which was in rapid motion. To the utter amazement of this worthy artizan, the second machine instantly commenced to revolve with great rapidity in a reverse direction. When the attention of Gramme was called to this phenomenon, he saw at once that the second dynamo was performing the function of a motor, and that what was taking place was the actual transference of mechanical power through a small wire by the means of electricity. This singularly opportune occurrence being commented upon in the scientific journals, led to the almost instant recognition of the true place of the electric motor in the domain of mechanics. The late Prof. Maxwell, one of the master minds among electricians of the new era, expressed the opinion that the reversibility of the dynamo machine was the most important discovery of modern times.

(To be continued.)

ELECTRIC LIGHTING OF CARLOW.

Messrs. J. E. H. Gordon and Co., of 11, Pall-mall, are lighting the town of Carlow by electricity, the motive force being water power. The conditions under which this town was lighted may be of some interest, as showing what prompt work can be done by modern electrical engineering firms.

On a recent Friday Messrs. Gordon's representative in Ireland telegraphed that the Carlow Town Commissioners desired the electric light at once, and on the following Friday the town was illuminated by some dozen Brockie-Pell arc lamps and some 50 incandescents, and some of the principal shops were also wired and connected, the current being supplied by a Siemens dynamo erected in a mill in the centre of the town and driven by a water-wheel.

A long lease was taken of the Milford Mills, about 4½ miles from Carlow. A 45-unit alternating-current dynamo of the Elwell-Parker type, giving 2,500 volts E.M.F., was ordered, and arrangements were made to drive it from Milford Mills either by the water-wheel or a turbine which is being erected, and at times of heavy load by a combination of both. The current for the permanent lighting will be conveyed by overhead cables of the Fowler-Waring Company's make, insulated by the fluid insulators of Messrs. Johnson and Phillips. The transformers—of which, at present, there are eight 4 h.p. and four 2 h.p.—transform down to 50 volts. The low-tension current is conveyed direct to 12 arc lamps, and to a ring of low-tension mains supported on the same posts. At the centre of the town is a small distributing station for connecting the various circuits, and for disconnecting the long cable for testing purposes. There will be telephonic communication between the mill and this distributing station.

It is expected that the permanent lighting will be started at the end of March.

It may be of interest as showing how soon electric lighting becomes a necessity that on Messrs. Gordon proposing to take down the temporary plant, which they had erected for exhibition purposes only, the Town Commissioners stated that they could not do without it after once having had the benefit of the light, and arranged to pay rental for the temporary plant until the completion of the permanent plant.

Walsall.—Mr. Frederick Brown, of the Walsall Electrical Company, has been appointed to advise the Electric Lighting Committee of the Town Council on electric supply matters.

BOUND VOLUMES.

Vols. I. to VI. inclusive, new series, of "The Electrical Engineer" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

We may occasionally follow the lead of our American Contemporaries, especially when they point out a serviceable way. They are not backward in asking their friends to do all they can for the welfare of the paper. We ask our friends to remember us. No Paper that we know ever refuses Subscribers or Advertisers. Nor o we; in fact, we invite them, believing that they will get full value for their money.

Specimen copies of the paper will be sent on request.

REFORM IN CONSULTING ENGINEERING.

Now that the Dublin authorities have come to a decision as to the acceptance of tenders for the electric lighting of that far-famed city, it will be as well to recall the history of the affair and to make a few comments upon the peculiar features of the transaction. By an order of the Council, dated Oct. 22, 1888, a committee was appointed to apply for a provisional order, to obtain estimates, and to enter into arrangements with contractors. A further order of the Council, dated Oct. 29, 1888, enlarged the area to be lighted. On the 3rd May, 1889, the license for public supply was granted, and on the 24th June last the license for private supply. Advertisements were issued in September and the tenders were in due course received. The borough engineer and the consulting electrical engineer considered and reported upon these tenders. This report has not hitherto been published in a complete form, so we give it elsewhere in order that references thereto may be verified. Our readers are fully acquainted with the fact that considerable delay arose in definitely settling which tender was to be accepted, and in the end a combination was accepted. The reasons for this policy may have been all-powerful and sufficiently adequate to convince the most sceptical observer, but to an outsider the information divulged is not reassuring. According to what may be gathered from the proceedings, the report of the engineers put aside all but three tenders, particularly recommending one, suggesting as better a combination of two or, best of all, a combination of three. The third tender in the end was somewhat harshly treated, as will be gleaned from our history. Our task is an exceedingly difficult one, in that we contend the whole system of tendering was a wrong one, and yet to condemn everyone for following their leader seems to be casting a stigma unnecessarily severe. In the first place, then, we contend that a consulting engineer should draw up plans and specifications to guide contractors, and not merely issue a few guiding clauses, leaving the contractors to make their own plans, their own drawings, and their own specifications. The contractors are not on the same footing, and in the result the brains of able engineers are sucked, to their great detriment, by men who are incapable of initiating comprehensive and complete schemes. Our remarks are perfectly general. Dublin is not the only case in point. There are but few men competent to make plans, and up to the present moment the aim of less able men has been to get the ear of the authorities, get the position of engineer, issue advertisements asking contractors to tender on their own plans, then select a scheme, or pick and choose parts of suggested schemes, accepting some one or other contractor to carry out the work, not as suggested by that contractor, but according to his plans with improvements suggested by other competitors. The taking of a suggestion from a nonsuccessful competitor in this fashion is a flagrant breach of confidence, and the sooner a systematic attempt is made by contractors to condemn it, the sooner will they be relieved from the intolerable burdens which now encumber them in sending in tenders. Another point we would notice is to be found in timid, ignorant, and incompetent advisers refusing to consider eligible any piece of apparatus that has not been tested by years of use. It seems incredible that the veriest tyro in electrical engineering should make a suggestion of the kind, yet it is one of the conditions attached to obtaining the work of lighting one of our most important towns. To hear the criticisms upon engines and upon boilers one would imagine the world to have revolved backwards through three centuries, for even in these directions so many years' warranty is required. But we have jumped from Dublin to another town, where, however, we consider the position worse than at Dublin, because of the pretensions of the adviser. The engineers at Dublin followed the rule, bad and condemnable as it is, and can only be said to have erred. The worst mistake made in the case was in suggesting the adoption of part of Mr. Gordon's scheme, and giving the work to another contractor. Messrs. J. E. H. Gordon and Co. sent in a complete scheme with elaborate drawings—a scheme which it is allowed would, if carried out, save from £800 to £1,200 a year in working. Of the system—suggested, be it recollected, only by these contractors—the engineers report: "We are of opinion you will do wisely in arranging to adopt this system. It will involve an extra expenditure on the basis of the lower tender of about £3,000; but, as pointed out by Messrs. Gordon and Co., the economy will be equal to nearly 25 per cent. of electricity sold." Again, the engineers say: "Sub-transformer stations, as recommended by some of the contractors and endorsed by us." If our information is correct, and, according to the documents before us, we cannot detect anything wrong in the conclusion, no other contractor than Messrs. Gordon tendered on the sub-station plan. Well, the question of acceptance of tender was to be considered, and after having seen the competing tenders and schemes, we find the following letter sent out:

"Engineers' Office, City Hall, Dublin, Dec., 1890.

"Dear Sir,—Please let me have, by 12 o'clock to-morrow (Tuesday) at latest, the extra amount to be added to your tender for sub-station transformer system (if used).

"There must be one line of cast-iron pipes for the H.T. primary wires, two lines of cast-iron pipes for three-wire distribution, and two lines of cast or wrought-iron pipes for arc light wires. There should be seven sub-stations, each with 10-4 H.P. electrical transformers, and each with a switchboard, enabling each pair of transformers to be connected as to the primary mains, and a three-way double-pole switch to each pair of transformers, the pair of transformers to be connected on to two or three wires of the distribution system.

"This addition to tender must include extra cost of cables, which must be to original specification as regards loss of energy. Please also state diameter of pipes.—Yours faithfully, "(Signed) SPENCER HARTY.

"W. G. Bingham, Esq.,
"House-to-House Electricity Co., Dublin."

No doubt the preparation of a tender is a simple matter in Ireland, at least so one would suspect, otherwise how could an engineer expect a revised tender, revised drawings, revised plans, etc., by "12 o'clock to-morrow." The position of affairs of course leaked out, and some pretty straight language was used by members of the Council. One gentleman is reported to have commented on this action in the following language:

"You will see in this letter that the House-to-House Company are asked to give tenders for a sub-station system at a few hours' notice. Now I assert that this is proof positive they were asked to copy Mr. Gordon's plans, for our engineers must have very well known that though it might have been possible to copy plans in a few hours, it would have been ridiculous to have asked any company to independently design that system in that time. I find that to work out the system in Mr. Gordon's office occupied the whole time of three skilled men for six weeks, and Mr. Gordon informed me that quite recently, having to design this system for another town, it took 16 days, even though the staff had the whole of the Dublin plan and calculations before them; this only refers to the details of the sub-station system, and not to the whole system. Before the dates of these letters the report was completed, and in that report we intended to recommend that the Electrical Engineering Company should be accepted, and that they should be allowed an extra sum of about £3,000 to adopt the sub-station system, and, in fact, we believed the labours of the committee were concluded, when we were suddenly called together again to reconsider our report. It then appeared that Mr. Gordon had heard of the proposed recommendation of the committee, and having remonstrated in writing without success, had come over from London and had called upon the chairman, Councillor Robinson, and had told him that he would be reluctantly compelled to apply for an injunction against us if we allowed his plans to be appropriated by others. A discussion ensued, and Mr. McSheehy was called in and asked whether we could legally adopt Mr. Manville's recommendation. The law agent replied that he could not give a legal opinion without further consideration, and his words were: 'It is a gross piece of piracy, and I won't help in it.' Notice of motion was then given by me to rescind the resolution, and, according to our rules, the meeting to consider my motion was adjourned for a few days. At the adjourned meeting Mr. Manville, who was sent for specially from London, was present.

"Now I will ask the members to kindly follow me when I tell them what occurred at that meeting, as I consider this a very important point.

"Mr. Manville at this meeting again informed us that, in spite of the opinion of our law agent, the Electrical Engineering Company could use the sub-station system, which he recommended, and Mr. Kennedy, the late Lord Mayor, and myself asked Mr. Manville a question, which we considered so important that we had previously put into writing; it was this: 'Have you in any of the tenders, except Mr. Gordon's, or in anywhere else in practice, seen or heard of the sub-station, practically or commercially, worked out?' to which Mr. Manville replied 'I have *not*.'

"Mr. Manville, finding that he could not persuade us to take the system, turned round, and then persuades us that there was nothing in it, and that it was not worth having. He told us then that the gross saving would not be more than £500 per year, which would be almost entirely swallowed up in the extra expense involved. In view of this statement of our engineer, we decided to save the capital cost of the sub-station system, and we recommended for acceptance the Electrical Engineering Company on the old system without sub-stations, which is the report you now have before you."

Consideration for our readers' patience prevent us pursuing this subject further at present. We have said enough to show that matters concerning specifications, plans, and tenders must come to a crisis. We have endeavoured to precipitate the crisis, and can go but one step further, which step we shall not hesitate to take, unless certain consulting engineers reform their methods of procedure. No consulting engineer has a legal or moral right to seek fishing plans, to put contractors to great expense, and then use the plans. He has no more right to give information to one contractor of the information supplied by another contractor, than he has to appropriate personal property to his own use. We were wrong perhaps in saying there was only one step more; there are two: (1) consideration of the question by the Institution, (2) the final—viz., legal proceedings. Lastly, we have used Dublin but to give point to our tale. The past is past; it is future trouble that may be prevented.

CANTOR LECTURES.

On Monday last Mr. Gisbert Kapp gave the first of three lectures in the theatre and under the auspices of the Society of Arts. A little consideration will show the great benefits conferred by the society in appropriating some of the Cantor lectures to electrical subjects, especially when it is remembered that Profs. Adams, Forbes, Lodge, and Thompson have in previous series dealt with special points concerning electrical engineering. And now Mr. Kapp is treating the subject of "Electrical Transmission of Power." This is an extremely interesting and at the same time an extremely difficult subject, especially when considered from the intensely practical standpoint of "cost," and this was the whole gist of Mr. Kapp's first lecture. We trust that Mr. Kapp, before he concludes his course, will make it perfectly clear that the data obtained from Mr. Fraser relative to the cost of running the Barking tramway is scarcely the right kind to be put forward for argument. The Barking tramway was, and to a certain extent is, an experimental line. Those who undertook it had something to learn from experience, and although it might have been necessary to depreciate the original type of accumulator used at the extraordinary high rate of 66 per cent., surely the improvements introduced will considerably affect this rate of depreciation. No doubt Mr. Kapp will tell us he was obliged to do his best with the meagre figures obtainable, and if he will only make this clear there will be no fault to find. We are told that experience has really gradually lessened the cost of running, so that now 8·068d. per car mile is considerably in excess of the actual cost. An examination of the figures given by Mr. Kapp shows that the depreciation of batteries alone came to 2·818d. per car mile.

Taking another point, we must congratulate Mr. Kapp for having dwelt upon a necessary proviso. The indiscriminate use of motors for power purposes, even when a central station is handy, will not pay the users, although it might pay the suppliers. From time to time we have insisted that the central station management will ultimately look to the supply of power first and light afterwards. Perhaps we have not fully explained our views when touching upon this question, but they are absolutely in accord with those put forward in Mr. Kapp's lecture. It is the intermittent user, the grocer who grinds coffee two hours a day, the butcher who chops meat for sausages a similar time, the jeweller and the watchmaker who want power occasionally, the dentist, the hundred and one other trades, not forgetting the printer who employs power at odd times and for comparatively short periods of time—these are the people who would benefit by, and who would benefit the central station. These are the people we want to convince that the electric motor is the cheapest apparatus they can employ when that motor is supplied with current from a central station. There is another class of people to whom power by a motor would be advantageous—those cramped for room, and to whom another machine, or another use for the space left vacant by the steam or gas engine, would mean increased profits far and away in excess of what they paid for power. In large towns, where special industries are aggregated about a common centre, want of space and cost of space is a far more important consideration than what is paid for power. Of course, these extraneous considerations cannot well come under review in what are more or less scientific lectures, but they will influence a great many users of power when electrical apparatus is better understood and becomes more common.

ELECTRICITY IN WARFARE.

On Tuesday last an interesting discussion was evoked by a paper read before the Aldershot Military Society by Major Hippisley, the subject being "Electricity, and its Tactical Value for Military Operations." As a matter of fact the discussion turned almost wholly on the application of electricity to lighting purposes. There seemed to be a general concensus of opinion that search-lights were most useful for a defending force, but not so useful for an attacking body; and General Sir Evelyn Wood stated that in one of the Egyptian campaigns he never went to sleep without turning the light on the enemy to see whether they were moving. The chief difficulty in employing a portable search-light appeared to the officers present on Tuesday to be the question of traction. To begin with, the pattern adopted in the English army was said by Major Hippisley to weigh seven and a half tons, against the four tons of a continental make. This is a very serious difference, which becomes the more apparent when it is further stated that an ordinary army team of horses is only supposed to draw one and three-quarter tons on a made road. And the less horses an expedition is burdened with the better. In fact, it does not seem to be a question, as Major Beresford pointed out, of whether the electric light is a useful adjunct to an army, but whether its utility is such as to counterbalance the cost and difficulty of transport. When considering this point, it must not be forgotten that the engine which drives the dynamo for supplying current to the search-light will also pump water and cut wood. Surely, however, our Royal Engineers can produce something lighter than seven and a half tons, if a foreign power, presumably France, for whom we believe Messrs. Sautter, Lemonnier, and Co. make this class of apparatus, can turn out an engine, dynamo, and wire-reel, mounted on a four-wheeled carriage, which weighs only four tons. Of course, it depends upon the length of wire carried, but even this weight should be capable of reduction.

RESTARTING OF THE DEPTFORD STATION.

The supply of current from Deptford station was recommenced on Monday. Since the fire the distributing station at the Grosvenor has been refitted with transformers, and the distribution is now effected by the current from Deptford at the full pressure of 10,000 volts transmitted along 16 miles of mains, no engines being now working at the Grosvenor. The load has been taken up gradually, 10 customers or so a day being put on, and many of the West-end circuits are now working. The supply is not yet put on continuously, but the service is from four in the afternoon to two in the morning. Before starting, trial runs were made by sending the current to Deptford and back for 24 hours continuously, and after one of these runs, and before putting on the customers, a trial was made running up the whole high-pressure part—dynamos and mains—to between 17,000 and 18,000 volts—going up from 15,000 to 17,000 within a quarter of an hour, the load being taken off in a water-tank resistance at Deptford. The supply has been on during the whole of this week and is again rapidly extending. The distribution of electric light is thus commenced on a practical scale from a distance comparable to the circumstances of a large gas works, and its progress henceforward will be watched with the keenest interest by electrical engineers and gas directors.

A GERMAN ELECTRIC LIGHTING AND POWER BILL.

The development which has taken place in the applications of electricity to lighting, power, and other purposes in Germany during the past few years, has induced the German Government to draft a measure to exercise a certain control over electric lighting stations, overhead and underground wires, installations, and factories where electrical apparatus is made. This Electric Lighting Bill has now been introduced in the Bundesrath. It comprises 15 paragraphs, of which the following are the principal regulations :

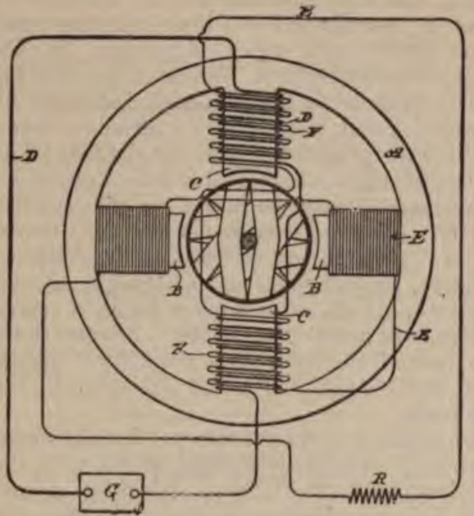
The erection and working of installations for the production, distribution, and application of the electric current for lighting, transmission of power, and other purposes, are to be controlled by the police regulations, which the Bundesrath will issue. Electric conductors or cables, intended to be carried along, over, or under public streets and ground, must be laid or put up in such a manner as not to interfere with existing electrical installations, or prevent the future use of the ground for the establishment of telegraphic, telephonic, or signal systems. The consent of the higher administrative authorities must be obtained before any installations, necessitating the breaking open or disturbance of public thoroughfares, can be put up. For installations established before the promulgation of this law, permission is not required, provided that the owners forward within six months a description of their existing installations, together with explanatory drawings, to the higher administrative authorities. Notices of intended installations must be forwarded to the Imperial Telegraph Administration, which is authorised within a period of four weeks to oppose the carrying out of the installation. The decision will depend upon the higher administrative authorities, but an appeal may be made to the country central authority (Landes-Centralbehorde). If, however, the Imperial Telegraph Administration is interested in the installation, the complaint or appeal must be made to the Bundesrath, which, after hearing from the country central authority, will decide the matter. Should the objections not be proved, the opponents must bear the costs. Permission must be obtained before alterations in installations can be made.

These regulations do not apply to installations erected on the property of railway administrations, or to those on the land belonging to the Imperial Telegraph Administration. Electrical installations in public exhibitions, etc., and in rooms or factories where explosives are manufactured, or where explosive gases may accumulate, must be examined by the local police authorities before being put into operation. Contravention of this regulation will be punished with a fine not exceeding £15, and the working of the installation may be suspended. The country central authorities are to determine which authorities are to be regarded as the higher administrative authorities. The Bill has been framed owing to the great extent to which electricity is now used for lighting and other technical purposes, and the Bill concerns generating stations, cables and conductors, installations, and electrotechnical works. The dangers connected with these installations consist in the possibility of accidents taking place owing to human beings coming into contact with electrical apparatus, the danger of fire, the possible interruption in the public telegraphic and telephonic services through short circuits or induction, and the breaking of thick, tightly-strained overhead conductors carried over streets and houses. In order to obviate these dangers, precautions must be taken that all electrical installations are carried out in the most efficient manner, so as to exclude the danger to life and loss by fire; the conductors must be erected so that no interruption will occur in the supply, and so that they will not break. A proposal was made that all electrical installations should be placed in the category of those trades included in the Trade Regulation Acts, but it was found impracticable. The present measure has therefore been elaborated for the purpose of controlling electrical installations, etc.

NEW TESLA ALTERNATING MOTOR.

We have already described a number of different forms of alternating-current motors designed by Mr. Nikola Tesla, depending upon a variety of phenomena met with in the employment of alternating currents. One general type of these consists of a machine with, say, four poles, between which is mounted an armature, generally wound with closed coils. On two opposite poles of the field are primary coils connected up in the main circuit. On the same cores are also wound secondary coils, which are closed through coils on the other pair of poles. When an alternating current is caused to pass through the primary coils, it energises directly one set of poles, and induces currents in the secondary coils, which in turn energise the other poles ; but the phases of the current in the secondary coils may differ in time from those of the primary current, and hence a shifting of the poles is effected that imparts a rotation to the motor.

In the new motor designed by Mr. Tesla, however, two energising circuits are brought into inductive relation in the motor itself, and the employment of an external induction device is thus avoided. The operation is dependent upon the existence of a certain difference of phase between the currents of the primary and secondary coils, and will be readily understood by reference to the accompanying diagram.



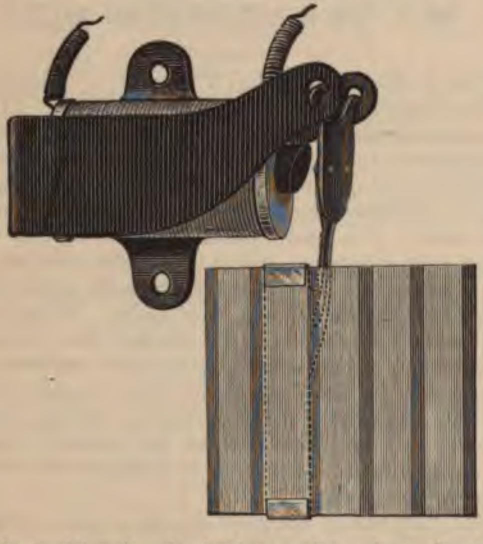
Here A represents the field magnet of a motor, which is built up of sections or plates. B and C are polar projections upon which the coils are wound. Upon one pair of these poles, as C, are wound the primary coils, D, which are directly connected to the circuit of an alternating-current generator. The secondary coils, F, are wound on the same poles with the primary, and connected with other coils, E, which surround the poles B.

The current in both the primary and secondary coils will lag behind the impressed E.M.F., but to secure the proper difference in phase between the primary and secondary currents themselves, the resistance of the circuit of the secondary is increased, so as to reduce as much as possible its self-induction. This is accomplished by making the coils E of comparatively small wire, having but few turns around the cores, or by inserting in the secondary circuit an artificial resistance, R.

In practice, it has been found desirable to wind the armature with closed coils, in which currents are induced by the action of the primaries.—*Electrical Engineer*, New York.

"NEW ERA" INDICATOR MOVEMENT.

A new and very simple pendulum movement for electric indicators is illustrated herewith. It consists of an iron frame, stamped out of one piece of metal, the two sides forming, at their extremities, bearings for the knife-edges of the pendulum, while between them is fixed the electromagnet. At the centre of the arm which, when the movement is in position in the indicator, is against the back of the case, are two eyelets, which afford the means of attachment to the same. It will thus be seen that as the whole movement only consists of two pieces—namely, the frame with magnet, and the pendulum—it is almost an impossibility for it to get out of order.

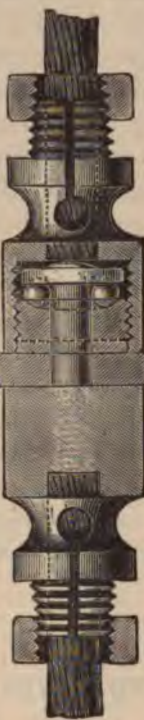


The method of working is as follows: Upon closing of circuit the magnet attracts the pendulum. When the circuit is again opened the pendulum is released, but as it is provided with knife-edge bearings, as pointed out above, it will swing backwards and forwards for a considerable time, thus attracting attention. The brass piece which carries the swinging indicator is carried up to prevent the magnet sticking.

The instrument requires no adjustment, and we think that the problem of a reliable, effective, and cheap indicator movement has been well solved by the production of the "New Era" movement, as it has been named by the International Electric Company (Mix and Genest), who are introducing it. The cost of such a simple piece of apparatus is naturally extremely low.

We may mention that the design has been registered under No. 162,129. It is an extremely clever and neat little piece of apparatus.

THE GWINNETT SWIVEL CONNECTOR.



A handy connector for securely and easily connecting up electric wires or cables is one of those little fittings often wanted and much desired by practical electrical engineers. Many patterns of screw connections have been brought out ere this, but a new one having some merits of simplicity and security is shown herewith, the patent of Mr. R. Gwinnett, of 7, Bath-street, Birmingham.

The union is made wholly of brass or gunmetal, and has a clamp at each end to hold the cable or wire. These clamps each consist of a lug, having a hole into which the end of the cable or wire can be pushed. Each lug is split, and has a taper screw-thread fitted with tightening nut, as shown in the figure. The electric conductor having been inserted, the clamp is tightened up by means of the nut to hold the conductor temporarily or permanently, as may be required. It will be seen that the conductors can thus be connected and disconnected with great ease and quickness, and great facility is thus afforded for setting out installations or effecting any alterations or repairs at a minimum expenditure of time and labour, and without the use of solder.

The union is fitted with a swivel of novel construction—an application of the well-known ball-bearing principle, allowing each half to turn round separately of the other. This allows for all twists, turns, or adjustments of the cables or wires, and takes out kinks without strain. This swivel is peculiarly suited for connecting the conductors for portable lights, etc., and the joint is so made as to be proof against dust and dirt. Quick connection and disconnection of conductors is assured, and the use of solder entirely done away with. For workshop and temporary use they will offer great convenience and saving of time. These swivel unions are made in running sizes, to suit the smallest wires and the largest cables, and their cost is very moderate.

Indian Telegraphs.—The new telegraph line from Calcutta to Bombay, *viâ* the Bengal-Nagpore Railway, will be opened for traffic at the end of February. The Telegraph Department will complete their new telephone exchange at Cawnpore this month. It is intended to open a similar exchange at Mandalay. Extensive repairs are to be carried out this year in two cables which link Ceylon with India. There are numerous faults which require to be repaired, particularly in the older cable, which was laid a quarter of a century ago.

ELECTRIC CRANES.*

BY REGINALD BOLTON.

The use of hoisting machinery is as widespread as trade, and as ancient as the Christian era, and forms a subject of interest to many engineers, while the question of its economies is of even deeper interest to all those engaged in the transport or movement of materials.

The application of electricity to this particular purpose is one that at first sight may not present great apparent advantage, but a consideration of the conditions to be fulfilled will, on the contrary, show that there is no more suitable conjunction of force and duty, and even at the present stage no purchaser of hoisting machinery can afford to disregard the claims of the conveyance of power by electricity, for reasons which the author hopes succinctly to show.

There are three considerations which present themselves, and which, if answered affirmatively, cover the whole subject.

Naturally, the primary one is (1) its comparative economy. The second in order is (2) its superior merits. The only remaining consideration being (3) its practicability.

Under the first we have to look into a few of the figures of electric and steam motors on cranes.

Now, an electric motor is in itself a most economical transmitter of power, its efficiency running as high as 90 per cent. in regular work, and if worked under proper conditions, its life may be as long as that of any ordinary steam engine, while under the special safeguards designed by the author its durability would be far more prolonged.

But the power must necessarily be generated and conveyed to this motor, and so the question of the economy of the generating dynamo and the power that drives it comes into question.

Such directly-connected engines and dynamos as are used on board ship, and in numerous central station installations on land, have repeatedly given a united efficiency of over 80 per cent. of the horse-power of the steam in the cylinder.

There are a far greater number of cases, however, where such a dynamo would receive its motion direct from a shaft driven by a larger engine, and in such a case an even superior result might be relied upon.

It would, in fact, be safe to assume an output of 85 per cent. of the actual power put on to the dynamo pulley, in the shape of electrical force, and as, in the case of shop cranes or wharf cranes, they would not be remotely situated from the generating dynamo, the loss in transmission would be small and can be stated at 1 per cent. to 2 per cent. only.

In the case of a large dock, with cranes situated at all parts, there would be greater distances to be dealt with, but even these would not exceed the limits of ordinary low-tension circuits, and the system would show a very favourable comparison in losses by transmission, as against the distribution of hydraulic power.

For all ordinary conditions, then, we may deal with the following figures :

1 h.p. put into dynamo results in............	·85 of 1 h.p.
Less by loss in transmission 2 per cent ..	·0085 ,,
Leaving the force put into motor as	·8415 of 1 h.p.
Output of motor 90 per cent............... =	·7573 ,,

Or a total loss of less than 25 per cent. Now take the comparative case of a steam-driven crane, say, of two tons power, having two cylinders each 5½in. diameter by 8in. stroke, running at 150 revolutions per minute. Such engines are on full work linked up to cut-off steam as late as ⅝ to ¾ of the stroke, and thus exhaust their steam at a considerable pressure. The usual boiler pressure is 70lb., maintained at an average of about 65lb., and wire-drawn by pipes and connections to, say, 60lb. initial pressure.

Under above conditions they indicate about 14½ h.p., but their consumption of steam is very considerable, and cannot be assumed at less than 35lb. per horse-power hour.

An excellent authority gave recently instances of such small high-speed engines absorbing over 40lb. per horse-power hour.

The net efficiency is still further reduced by the internal friction of the machines, which even in good engines would average 15 per cent., so that we arrive at a final efficiency of these engines used as motors on cranes of not more than 60 per cent.

On all small steam cranes, however, there is a further waste in the boilers, which, being small and of the vertical type, are far from economical in raising steam, and habitually consume 5lb. to 7lb. of fuel per horse-power per hour. In practice no crane is ever continually at work, and during the periods of lowering, changing gear, and stops, etc., the fuel continues to burn, and there is also the cost in fuel and labour of raising steam in the morning for the day's work.

It is customary among crane-builders to construct the boilers of steam cranes a good deal smaller than would be necessary if the engines were in constant running—the gain in pressure during the stops and changes mentioned compensating the loss of pressure during working, and the steam-gauge is consequently constantly on the move.

Now, against these figures we should have, in the case of a direct-driven dynamo, a better engine running with an earlier cut-off, and also necessary steam more economically raised. The motor when the crane is standing wastes no power, and the dynamo may be shut down or started at short notice. The crane driver need pay no attention to the crane when standing idle, and he starts without delay in the morning, the power being derived from the shop boilers.

There would thus appear to be a very decided economy in favour of the electric cranes, as against steam-driven machines.

In the case of overhead travellers, there is the saving due to the absence of long square shafts running in movable bearings, and which, together with the cotton or wire ropes in rope-driven cranes, are kept constantly running even when the crane is out of use.

ELECTRICITY IN WARFARE.

On Tuesday, Major Hippisley gave a lecture at Aldershot on the subject of "Electricity and its Tactical Value for Military Operations." The chair was taken by Field-Marshal Sir J. Lintorn Simmons, G.C.B., etc.

Major Hippisley pointed out the principal uses of the electric light in war, showing that they were of little use for the attack, but of enormous use in the defence. He maintained that the military were not yet fully alive to the importance of possessing portable search-lights for field operations, and drew attention to the fact that many foreign nations were far ahead of us. It behoved the War Office authorities to adopt some system of portable electric lighting, and he thought they could not do better than take pattern by their continental neighbours.

Lieut.-General Sir Evelyn Wood said : I want to indicate a point on which I should be glad if some of you will express your view. It has been said that no vote has ever been gained in the House of Commons by a speech. Now, I am on the opposite side to-day, though I am thoroughly convinced that no one could have put the case for the electric light more fully than the lecturer has done. I found the electric light of inestimable value at Kafr Dowar, and I never went to sleep at night without throwing the light in the direction of the enemy to see if he was moving ; and I had the same precaution taken several times during the night to make sure there was nobody moving outside the Egyptian lines. We did not know at the time how inert the enemy were. Is there a battle since 1859 in which the electric light could have been used by the aggressors. I do not say, Is there a battle in which the electric light was used by the aggressors, because that could be answered at once. It might be said it was not used because we are not sufficiently advanced. But has there been one battle fought within our memory in which the electric light could have been used by the attacking force with advantage? Perhaps some of you will tell us your view. I am possibly wrong. But I should like to know if you could ever get it up without being discovered in a night attack. The object of such an attack is, of course, a surprise. Now the noise of the engine alone would be heard long enough before you reached the enemy by a quick-eared scout. And then there is the unavoidable noise that would be caused by the pulling of horses. What is the weight of our engine?

Major Hippisley; Ours is 7½ tons; that one (indicating a diagram of an engine of continental pattern) is only four tons.

Lieut.-General Wood : Well I have asked Colonel Gratton, of the Army Service Corps, how much he expects a team to pull, and he says 1¾ tons on the level road. My experience of the engine is that we could not take it off the best macadamised road to get into the camp where we wanted it. It was practically impossible, and we had to leave it on the macadamised road, and never got it any further ; even if you got the weight down to 2½ tons you could not take it in and out of the camp unless you had a line of macadam. There is an officer present who will remember that we got nine battalions of men within 400 yards of a position we were going to assault, without being heard, and saw our friend strike a light to light a cigarette. It illustrates the importance of little things in a night attack. Now, if we do away with engine power we shall want more horses, and the General on the line of communication will object to every beast extra. He will fight against the artillery having more horses because it only adds to his difficulties as regards supply. I have taken intense interest in the lecture, but nobody will believe in it, unless they are placed in a position in which they mean fighting to the last man ; and I cannot find its utility for attack.

Major Beresford, R.E., said : There is one view of the electric light which I may be forgiven for mentioning. Major Hippisley, in advocating the cause of the electric light, forgot what in any branch of the service is always brought conspicuously forward—I mean moral effect. The artillery has its moral effect ; the cavalry has its moral effect ; and so has the new magazine rifle. So I think the electric light has its moral effect. Unseen dangers are always the worst, and I can easily imagine that a cheerful ray of light showing that there is no immediate danger ahead, would have its effect on the spirits of the men. I think the electric light would have a very good moral effect. The point to be decided, however, appears to be not so much, Will the electric light be useful on certain occasions? Everybody seems to admit that it will. What everybody wishes to know is whether the frequency of such occasions will be sufficient to warrant the expenditure for transport that will be necessary. It can be shown that the engines will not only be used for electric lighting but also for pumping water and cutting wood. I think since we have such a small army, and such a limited number of men, anything in any way that science can help us in we should take advantage of.

Colonel Lonsdale Hale said : I asked a question on one occasion as to whether the electric beam would penetrate Colonel Crease's smoke. Some people seem to think Colonel Crease's smoke a fad. Now, I have seen it tried at Portsmouth, and it is not a fad. At present the apparatus is somewhat cumbersome, and if Colonel

---

* Paper read before the Civil and Mechanical Engineers' Society on Wednesday.

Crease can reduce it to portable proportions it will become a potent factor in the attack on a position. In the course of the experiments at Portsmouth, a body of men advanced within 200 yards of a position unseen under cover of the smoke. I bring this forward in connection with the electric light because it is important to consider. Sir Evelyn Wood took me to the other side of the Fox Hills when the electric light was being tried, and I thought if we have this smoke cloud, which can be made very portable, it will render the electric light comparatively useless in the field for search purposes. I think the smoke is one of the difficulties that Major Hippisley should have dealt with. With regard to another point mentioned by a previous speaker, there are very few battles carried on at night. If, instead of enquiring whether the electric light can be used for attacking purposes, we consider its uses on the battle field for the purpose of finding where the enemy is, I think we shall find that it may be uncommonly useful. After the battle of Coulmiers the defeated rested within a stone's throw of the men who had won the field. If the electric light had been there to search, the defeated enemy might have been pounced upon again, but in the absence of cavalry they did not know that the enemy lay at their feet. With regard to pushing forward the specialities of engineers, I think there will be little success in this direction until the department at Chatham is removed to Aldershot. Not the slightest progress can be expected with the useful specialities of the engineers until they are better established at Aldershot Camp. I am afraid the terrible diagrams Major Hippisley has placed before us are not much understood. We have tried our experiments at Chatham, and no good at all has resulted. We want our experiments tried here among the rough-and-tumble of Aldershot in contact with other troops. Only by these means shall we be able to make these things practicable. To the officer commanding the balloon section I should say; "I am not going to trust you as you stand at present. I will let you know every scheme I am going to carry out, and you shall do your level best to make use of your opportunities, and as you overcome your difficulties you will become more and more useful." It is only by bringing our specialties to light and working them out that you who are not engineers will believe in them; and if we have not the opportunity to do this at Aldershot, many useful inventions will remain pretty toys t Chatham.

Colonel Brine, R.E., said: What the last speaker has been laying down is being acted upon, and we are receiving most loyal support from Chatham. When we used the electric light last year the officer in charge was a distance from the light, and there was some little confusion, but that will not occur again.

The **Chairman** said: I have listened to this lecture with the greatest interest, but I think there are some points which require serious attention before the electric light is introduced into the service. I think there is great danger attending it because people will trust in it instead of trusting to the outposts. Tel-el-Kebir is often quoted as a night attack that might be copied. On that occasion there were no outposts whatever—I think not. The march on the night was undertaken under favourable circumstances. There were no hedges or ditches to get through; yet on the march the troops very nearly came to a disaster. I am told that the wings closed upon one another, while the centre did not march so rapidly, and the men came almost face to face. These night attacks are very dangerous and should not be adopted except under favourable circumstances, when the country is thoroughly well known, and the troops are well trained. Night attacks under other conditions will be attended with enormous risks, the troops, when they arrive at the position, will be unusually fatigued, and they will be alarmed by noises in the night, so they cannot be depended upon in the same way as in the daylight. Major Beresford speaks of the electric light as having great moral effect. I do not believe in the moral effect of the electric light if used for the purpose of attack. It might assist them in keeping their position, but I do not think it would otherwise assist them one atom on the march. It is very difficult to bring up three tons. As for four tons being drawn by four horses, you may as well try to move this hall with four horses. Four horses will not draw four tons over heavy ground, and on a newly-macadamised ground they would not move it at all. You need not be afraid of a locomotive. Although it could not pass over the bridges spoken of just now—the bridges near the Staff College—still it is capable of going over rough ground. Several years ago I saw eight or ten different kinds of locomotives tried at Birmingham. The course marked out was over a mile over hedges and ditches, and across ploughed fields. In the hedges an opening was made, a little wider than the engine, and the earth was thrown into the ditches. The locomotives were started and they went over the fields and the ditches, and it was quite an interesting steeplechase across country. Some of them stuck fast, I believe, and were never got out, but the majority of them got to the end of their journey and did remarkably well. You need not be afraid of the locomotive. It is best both for short and long distances; it is reliable, and does not get out of order as quickly as horses, and its "forage" is not so difficult to procure. There is another important consideration in connection with the electric light as a search-light. When used for coast defence you have a great expanse of level plain—water—and therefore the light can be thrown a very great distance without meeting with any obstacle. On land it is very seldom that you get such a favourable level, and it is seldom that you find a plain in which there are not holes sufficient to conceal large bodies of troops, and whom you could not see unless there was a man up in a balloon while the electric light is being used. I must ask you to accord a hearty vote of thanks to Major Hippisley for his valuable and interesting paper

REPORT OF THE ENGINEERS ON TENDERS FOR DUBLIN ELECTRIC LIGHTING.

APPENDIX A.

To the Chairman and Gentlemen of the Electric Lighting Committee.

Gentlemen,—We beg to submit herewith a detailed analysis of the various tenders received by your committee for the above. It has been a work that required a great deal of time and care in order to bring out the various points in the several tenders, and to put them in such a shape as will make the comparison easy to your committee and the members of the Corporation generally.

On the full consideration of these tenders and estimates, we find the prices estimated for the buildings vary so much, that we have eliminated this item altogether, in order to make a satisfactory comparison between the tenders. The design for the buildings will be a matter for future consideration, and in dealing with this portion of the work, we estimate that a sum not exceeding £4,000 will be required.

The bulk of the tenders for Specification B (boilers) provide for Babcock and Wilcox boilers, with the exception of Messrs. Crompton and Co., and Messrs. Gordon and Co. The description and tracings accompanying the various tenders for the Babcock and Wilcox boilers are identical in every respect, the prices only differing. The two firms above alluded to tender for Mills's patent boiler, which is much of the type of Babcock boiler, with the addition of a small water-jacketed furnace, and is said to give very excellent results. In the following analysis of the various tenders, therefore, no further mention will be made of boilers.—We are, Gentlemen, your obedient servants,

SPENCER HARTY.
EDWARD MANVILLE.

Analysis of Various Tenders Received for the Dublin Corporation Electricity Supply, 1890.

MESSRS. HORNSBY AND SONS.

Messrs. Hornsby and Sons' tender is moderate in price, and all the plant seems to be of good design, the electrical machinery particularly. The engines are substantial, but not quite of the most modern design. The electrical part of the machinery is altogether of Johnson and Phillips's manufacture, and as this latter firm's tender is identical with that of Messrs. Hornsby's, and exceeds Messrs. Hornsby's tender by £709, we do not propose to consider Messrs. Johnson and Phillips's tender. The alternators are of the Kapp type, the armatures revolving. This point is objectionable, it being the more usual practice to make the field magnets revolve, the armature carrying the high tension and dangerous current being stationary. The exciters also are coupled direct to the armature shaft, and in the event of these machines being adopted, it would be advisable to arrange with the makers to place a pulley on the end of the armature shaft to drive the exciter by ropes or belt, and thus prevent the possible breaking down of the small machine, incapacitating the alternator. The switchboards proposed by this firm seems to be well designed, and to meet the requirements of the case, with the exception that no mention is made of regulating apparatus, and there is no statement as to whether they would adopt automatic or hand regulation, or a combination of both. The transformers proposed to be supplied are, as far as can be judged from the drawing, of proper design—they are of the Kapp type. The meters tendered for by this firm are not described in any way, and it is therefore impossible to form any opinion as to their merits. It may be pointed out that the price for this item as tendered for by this firm is only half the price, with one exception, of all other tenders. This firm proposes two systems of main laying; the first consisting of Fowler-Waring concentric cables merely laid in a trench beneath the road surface, and otherwise unprotected. We are not aware that this system has been used anywhere in the United Kingdom for the conduction of high-tension currents. The same may be said of the second system proposed by them, in which a conductor roughly insulated with some hempen material is drawn into carefully jointed iron pipes, which are afterwards filled up with a heavy insulating oil, the pipe system being necessarily quite continuous. The second method would increase the price of their tender by £1,909, and it is important to note that their confidence in this system is such, that they would be prepared to guarantee the system of mains when laid by them for a period of five years. For the public lighting vertical semi high-speed engines, of their own manufacture, and of very suitable design, are proposed, driving Brush dynamos, supplying current to Brockie-Pell arc lamps on ornamental lampposts. The Brockie-Pell arc lamp is undoubtedly one of the best in the market, and the combination for this portion of the tender would be a highly desirable one. In connection with the exhaust-pipes it may be noted, that no mention is made whether it is proposed to carry the exhaust-pipe up through the flue, or to exhaust into the base of the flue, the latter plan not being at all desirable. Their price for the whole of the work, exclusive of the buildings, is £25,178.

MESSRS. SHARP AND KENT.

This firm's description is very incomplete. The engines are by Davey, Paxman and Co., and are likely to be of good design. The dynamos are not described, but, from the drawing attached, they appear to be of the type and manufacture of Goolden and Co., and the price tendered for by Messrs. Sharp and Kent is nearly twice that quoted by Messrs. Goolden and Co. for the same machines. The regulating apparatus and instruments are of Messrs. Sharp and Kent's design, but no particulars are given. Transformers, of the Goolden type. Meters, no particulars. Public lighting, no particulars. Price, without buildings, £33,580.

Messrs. Johnson and Phillips.

Messrs. Johnson and Phillips's tender is the same as Messrs. Hornsby's, except that the price is higher, and, therefore, need not be considered by us.

This firm proposes as an alternative to supply, under Specifica-A, Willans engines, coupled direct with Kapp alternators, without the intervention of belts or ropes, at a slightly increased price; and under Specification H, to replace Brush dynamos with arc lighting dynamos of their own construction, coupled also direct to Willans engines. This arrangement has the advantage of economising room considerably, and allows of a very perfect arrangement of steam-pipes, but we do not propose to recommend you to adopt high-speed machinery for this station.

Price, without buildings, £25,913.

Messrs. Edmundson and Co.

Messrs. Edmundson and Co.'s tender is identical in every respect but price with Messrs. Laing, Wharton, and Down's, and, therefore, is not considered here.

Price, exclusive of buildings, £34,267.

The Laing, Wharton, and Down Construction Syndicate Company.

The Laing, Wharton, and Down Construction Syndicate Company's tender is identical with Messrs. Edmundson's, excepting that their prices are lower. No particulars are given of the engines, except that they are of English make; the price for them is moderate. The only particulars given regarding alternators is that they are of the Thomson-Houston make, and there are no drawings. The transformers and meters are also of the Thomson-Houston type. The particulars of the mains and distribution systems are not given; this firm stating that they have included in their tender a price for a system similar to that in Newcastle. But they propose, if their tender is favourably considered, to place before you an entirely new method of electrical mains, which they believe will eclipse anything at present in use. In the public lighting they give no particulars of the engines to be used; but the dynamos and arc lamps are to be of the Thomson-Houston type. Their system of arc lighting is very well known and largely used. They state that the plant, with the exception of the engines, will be of American manufacture, and their price for the works, exclusive of buildings, is high—£32,240.

The Electrical Engineering Company of Ireland

Propose to supply compound engines, by Combe, Barbor, and Combe, of Belfast. It will be noticed that the size of these engines is considerably smaller than those of the same type provided for by the other contractors, the extra work being got out of the engines by running them at a considerably higher speed. In order, therefore, to make their price compare with that of other contractors, we have requested them to state the extra price for engines of a larger size, thus similar to other contractors. The reputation of the makers, Messrs. Combe, Barbor, and Combe is very high, and, though the general design of the engines is not so symmetrical as those of other more modern engine builders, their engines can be relied on as being of the highest class of workmanship and material. The alternating-current dynamos they propose to supply are those of the Brush Electrical Engineering Company's manufacture, of the Mordey-Victoria type. Their design is good, and they have attained a first-rate reputation. The switchboards, also of the Brush Company's make, thoroughly fulfil the conditions of the specification, and the combinations are neatly carried out. The instruments are of well-known types. Transformers also of the manufacture of the Brush Electrical Engineering Company's Mordey-Victoria type. The meters they propose to supply are Ferranti type, and they state, as an alternative, that they will supply meters of the Aron type. The system of conductors they propose is Callender's. This system is being largely used in London at the present moment, but we apprehend there would be an objection to the use of it in Dublin for the following reasons: The distance between the flagstones and the tops of the cellars in most of the streets through which the mains are to be laid is very small, and the Callender-Webber casings take up a good deal of room. This would involve the mains being laid generally under the roadways, and in that case the Callender casings, being but of weak structure, it would necessitate the laying of the mains some considerable depth beneath the road surface, thus very considerably increasing the expense of excavation and making good, which is to be done by the Corporation. In the event, therefore, of your proposing to accept this company's tender, they should be asked to reconsider the subject of main-laying, with the view of substituting cast-iron pipes and vulcanised rubber cables. The engines proposed for the public lighting are of good design, and are by Davey, Paxman, and Co. These engines drive Brush dynamos, regulated by Brush Giepel automatic current regulators. The company point out that the dynamos they quote for are each capable of supplying 55 arc lamps, if driven with a sufficiently large engine, and that their tender would be increased by the sum of £225 if engines of 60 brake horse-power were provided instead of engines of 30. This would enable one of the sets of plant to be kept spare, or it could be utilised to supply current to an extension of 50 more arc lamps, at this very small increase in price. The arc lamps proposed to be supplied by this company are of the Brush type. It may be well, if the company's tender is favourably considered by you, to suggest the substitution of Brockie-Pell lamps in place of the Brush lamps, the lamps being about the same in price, and the results given by the Brockie-Pell lamps being probably superior to those obtained from the Brush lamp. The lamppost as proposed to be supplied by them are of ornamental and suitable design. The company suggest as an alternative Specification A, the substitution of four engines of the Brush Company's make, running at a semi-high speed and driving four dynamos of a smaller size than those specified for, and supplying two exciters instead of four, not coupled to or driven from the dynamo shaft, but coupled direct to two of the Brush Company's engines. As before stated, we do not propose to advise you to adopt semi high-speed engines for the private lighting, and, in addition, the use of these engines would increase the price of their tender. The Electrical Engineering Company of Ireland point out that they are an Irish company, and that almost the whole of their capital has been raised in Dublin, that it would be their object, if the contract is allotted to them, to place as much of the work as possible in the hands of Irish manufacturers. Total price of their tender, exclusive of buildings, is £26,007.

Since the above was written, this company has sent in, at our request, price and tracing of engines of Messrs. Combe, Barbor, and Combe's make, of about the same ratio of work to size as those quoted for by most of the other contractors, and also tracing of an engine of about the same size by Messrs. Victor, Coates, and Co., and the price of their tender for either of these engines is increased to £5,658. Undoubtedly the workmanship and material on engines of both these makers is excellent, but, as stated before, the general design of the engines is not symmetrical and as massive as some of those quoted for by other makers. The Electrical Engineering Company of Ireland point out that engines of both these makers are built in Belfast. They also now quote for Messrs. Fowler's engines, their price for these being £7,308, and these engines are criticised under the Irish House-to-House and Messrs. Ryan and Purcell's tenders. Taking Fowler's engines as now quoted for, the estimate of this company amounts to £28,907, without buildings.

The Irish House-to-House Electricity Company

Have prepared a very complete tender, and the plant they propose to supply would seem to be of the highest character throughout. They attach a detailed tracing of the engines they propose to supply, but do not give the maker's name. From, however, this tracing, and the dimensions given, and the similarity existing between these and the particulars given by another contractor, it is fair to assume the engines are by Messrs. Fowler and Co., of Leeds. The price attached to Specification A for these engines is, however, exceedingly high, being no less than 50 per cent. above the price of the other contractors tendering for the same type engine. These engines have been very successfully used by the House-to-House Company for central station lighting, notably at Kensington and Madrid, besides, we believe, at some of the smaller stations, such as Hastings, Eastbourne, etc. The dynamos are of the Lowrie-Hall type, with stationary armatures and revolving field magnets. These machines are of the same type as those quoted for by two other contractors, and again the price is in both cases higher than the other contractors. These machines have been used in the same central stations as referred to above in connection with the engines. The exciters are uncoupled and driven by ropes off the alternator shaft. The regulating apparatus is automatic, and of the Lowrie-Hall type, and, in addition, hand regulation is provided. The alternating switchboard is very well designed, and also of the type used in the stations above referred to. The instruments are by Sir William Thomson and Cardew, and Messrs. Elliott Brothers. The transformers are also of the Lowrie-Hall type, ard of good design, being the same as used at Kensington, Brighton, Eastbourne, Madrid, etc. This firm gives a choice of meters, either the Ferranti, Shallenberger, or Lowrie-Hall. The system of mains they propose to supply is the same as that adopted by them in the stations above referred to, and consisting essentially of cast-iron pipes, 3in., 4in., and 6in. in diameter, arranged with surface boxes for drawing in and out cables, and junction boxes placed under the road surface opposite the party wall of houses, to enable the houses to be connected up. Into these cast-iron pipes are drawn cables insulated very highly with vulcanised indiarubber. No particulars are given as to the maker of the semi high-speed engines proposed to be used for the public lighting, but from the drawing and specification attached they appear to be of good design, and they are fitted with everything required to make them perfect in detail. The three continuous current generators are fitted with special automatic current-regulating apparatus, and supply current to Brockie-Pell lamps placed on lampposts of plain design. The company states that 25 per cent. reduction could be made in their estimate all round, if plant of a less costly kind be provided. They also suggest that the transformers, instead of being placed in metal cases as specified, should be placed in a brick chamber protected by an iron door, with lock and key, and also suggest that the double-pole switches should not be used at all at the transformers. They state that they are not limited to the use of the arc light plant included in their tender, and are prepared to supply in place of it, if required, any system at present in the market. It may be well to point out that this company, together with one other contractor, are the only ones who have furnished detailed specifications of each part of the plant proposed to be used. Their total price for all the plant, delivered and erected, excluive of buildings, is £31,398.

Messrs. Woodhouse and Rawson United, Limited,

Propose to supply engines of their own make. The design of these engines is rather antiquated, and it will be noticed that they have to produce a higher ratio of work compared to their size than any of the other engines specified by the remaining contractors. The alternator which they propose to use is of a type comparatively novel. It is called the Kingdon type of alternating dynamos, and its advantage is that the moving parts carry no current whatever. So far as we are aware the only town central station in which this type of machine is used is Woking, where they have been just started, or are just about to be started. Exciters uncoupled. The switch appliance is to be of their own manufacture, likewise the instruments, but the tender is quite unaccompanied with details of the apparatus, and they specifically state that they have not included the synchronising apparatus. The transformers they propose to use are of the Brush type. The mains are of the same type as proposed by several other contractors—*i.e.*, cast-iron pipes and vulcanised rubber cables—but the amount of their tender for this is astonishingly high. The engines for public lighting are of their own manufacture, and are to supply Brush dynamos giving current to Brockie-Pell arc lamps, and they have only included two sets of engines and dynamos for public lighting, large enough to do the work between them, instead of three as specified.

Their price, exclusive of buildings, is £32,043.

MESSRS. CROMPTON AND CO.

In addition to sending in a tender for plant according to specification, send in an alternative tender for plant on the three-wire low-tension system, which we have considered further on in this report. The engines they propose to supply are made by Messrs. Pollitt and Wigzell, 17½in. high-pressure cylinder, 28½in. low-pressure, with stroke of 42in. They do not enclose drawings of the engine, but it will be seen that the dimensions are larger than those specified by all other contractors, with one exception, and the reputation of the makers is a guarantee for a first-class article. The boilers they propose to supply are, unlike those tendered for by most of the other contractors, not of the Babcock and Wilcox make, but of what are known as the Excelsior, or Mills patent type. These boilers very much resemble, in their general arrangement, the Babcock and Wilcox boilers, with the addition of a small water-jacketed furnace. We notice that these boilers proposed by Messrs. Crompton and Co. are smaller in size than the Babcock and Wilcox boilers, proposed by other contractors. Thus, the total heating surface in the Babcock and Wilcox boilers is 2,531 square feet, and in the Mills boiler 2,126 square feet. In the Babcock and Wilcox boiler the total grate surface is 51 square feet, and in the Mills boiler 49 square feet, and the dimensions of tubes, and the various other portions of the boiler, are uniformly smaller throughout than the Babcock and Wilcox boiler. These boilers are said to have shown very high evaporative duty on recent test. The alternators proposed to be supplied by Messrs. Crompton and Co. are of the Kapp type, made by Goolden and Co., the exciters being of Crompton's own make and coupled. The regulating apparatus proposed to be supplied by them is not automatic. The switchboards, which are of their own make, are well arranged, but no mention is made of the makers of the various instruments proposed to be supplied, and therefore no idea of their value can be formed. The transformers Messrs. Crompton and Co. propose to supply are of the Statter type, arranged in perfectly water-tight iron casings, and are suitable for placing in the open air if necessary. The meters proposed by them are of the Aron type; the mains they propose to supply are vulcanised rubber highly-insulated cables. These cables they propose to lay in shallow conduits constructed under the surface footways in cement concrete.

This culvert would be divided into two sections by a brick partition, the positive wires being laid on one side, the negative wires on the other. We would point out here that the Corporation would be put to a considerably greater expense in excavation and making good by adopting this plan, and that also it would probably be unsuitable without considerable structural alterations for a considerable portion of the length of the mains, where they will have to be of necessity laid under the roadways instead of the footways.

Messrs. Crompton and Co. state that they only intend in this tender to lay a double line of culverts, one under each footwalk in O'Connel-street, and they do not enclose any map showing the run of the mains. For the public lighting plant they propose to supply engines of Davey, Paxman, and Co.'s make, but give no particulars. These engines would drive continuous-current generators, fitted either with their own constant-current regulator, or with the Statter constant-current regulator. The arc lamps are of their own make, and have earned a reputation for steady burning. The lampposts suggested by them are of handsome appearance. Messrs. Crompton and Co. state that the efficiency of the system might be much improved by the use of transformer substations in lieu of placing a separate transformer in the house of each consumer. We refer to this subject again later in this report.

Price, exclusive of buildings, is £27,154.

THE ELECTRICAL CONSTRUCTION CORPORATION.

The Electrical Construction Corporation's tender for engines gives no particulars, and therefore it is impossible to form any opinion of their relative value. Their price, however, is highest of all but one. Their boilers are Babcock and Wilcox. The alternators are of their own make, and perhaps have been used in larger numbers in the United Kingdom than those of any other maker. Their price for these machines is lower than the prices of the two other contractors who tender for machines made by this company. The regulating apparatus is only hand, and not hand and automatic combined. The switchboard is well designed, and the instruments by Sir William Thomson, Elliott, and Cardew. The transformers also are of their own manufacture.

The amount of their tender for Specifications A, B, C, D, and E is £20,831.

MESSRS. RYAN AND PURCELL

Propose to supply engines of Messrs. Fowler and Company's manufacture. These engines are practically identical with those proposed to be supplied by the Irish House-to-House Company, and it will be noticed the price is 50 per cent. lower. The boilers, by Babcock and Wilcox, are also quoted for at a price much lower than any of the other contractors. The alternator current dynamos of Statter type, with coupled exciter. These dynamos have not been used for central station lighting in the United Kingdom. In the event of this tender being accepted, we should advise that the contractors be directed to drive their exciters by ropes instead of having them directly coupled. The switchboards are of the same type as quoted for by the House-to-House Company, and are very complete. There is an especially ingenious device for both the automatic and hand regulation, which is to be worked by pressure obtained from the Corporation water mains. Switchboards are also well designed for extensions. The instruments are by Sir William Thomson, Cardew, and Elliott Bros. Transformers of the Statter type are stated by this firm to be the same as those supplied to Messrs. Crompton and Co. for the lighting of the town of Chelmsford, and to the same firm for the lighting at the Barry Docks. They propose to supply meters of the Ferranti type. The system of mains they propose to use consists of cast-iron pipes, 4in. in diameter, with cables highly insulated with vulcanised rubber. They state that two lines of pipes will be laid in most streets, and one line of pipes in others, probably the narrow streets. In the event of this tender being accepted, it would be better for the contractors to give an extra price for the laying of double lines in all streets. For the public lighting, vertical tandem compound engines, of the Allen or Gwynne, or similar type, are proposed running at 220 revolutions per minute, and driving generators of Statter type, with patent constant-current regulation. These generators supply current to Statter arc lamps, mounted in lanterns instead of globes, in very ornamental posts. In the event of this tender being accepted, we think that Brockie-Pell lamps should be substituted by the contractor for the one proposed. This firm do not include in their tender the price of lampposts, and a few extras in the public lighting, amounting in all to £1,024, and the price for the whole of the work, without buildings, inclusive of the £1,024, is £24,472.

MESSRS. J. E. H. GORDON AND CO.

Messrs. J. E. H. Gordon and Company's tender is perhaps the most complete one sent in, going, as it does, specifically into the smallest details of the plant proposed to be supplied by them. The engines they propose are by Robey and Co., fitted with Richardson's automatic trip expansion gear. The high-pressure cylinder, 17in. in diameter; the low-pressure cylinder, 30in. in diameter; stroke, 40in.; and speed, 75 revolutions. The engines are evidently of very excellent design, and large for the work they have to do. The boilers proposed by this firm are of the Mills type, previously referred to in this report under Messrs. Crompton and Co.'s tender. It is pointed out by Messrs. Gordon and Co. that the following efficiencies will be guaranteed by them for these boilers: When burning Lancashire engine coal, 9lb. to 9½lb. of water will be evaporated per pound of coal; when burning good Newcastle coal, 10lb. of water will be evaporated per pound of coal; and when burning good Welsh coal, 10½lb. of water will be evaporated per pound of coal. These efficiencies are exceedingly high. The whole arrangement of the engine-room, as proposed by them, is very well planned, there being a duplicate system of steam-pipes so arranged that any joint breaking will not shut off steam for more than one engine. The steam-pipes are to be of wrought iron or mild steel, with copper connection pipes, arranged to allow for expansion and contraction without the introduction of special expansion joints. The main exhaust-pipe also is carried right up to the top of the chimney, steadied by wrought-iron hoops. Considering the high class of the engines proposed to be supplied, and the excellent arrangement of steam and exhaust pipes, the price for the engines, £7,605, is not a high one. The dynamos they propose to supply are either of the Lowrie-Hall type, running at the rate of 350 revolutions per minute, with exciters driven by ropes, or of the Siemens type. Their price for the dynamos is £3,771, as against £3,675 for the Electric Construction Corporation. The regulating apparatus proposed to be supplied by them is of the type used by the Metropolitan Electric Light Company in their Manchester-square station. It is complete in its way, but does not provide for the combinations specified; notably, no mention is made of synchronisers, although, from the reading of another portion of their tender, it would be inferred the dynamos are intended to run in parallel. The instruments by Goolden and Co. For transformers the maker's name is not mentioned, but the price included for numbers specified is £2,534, or less than that of any other contractor.

Messrs. Gordon and Co. point out, as also does one other contractor, that they recommend sub-transformer stations, instead of placing separate transformers in each house to be supplied; and this subject is considered by us further on in the report. They propose to supply meters of the Westinghouse or Shallenberger pattern, and their price for these is lower than that quoted by other contractors for the same meter. The system of underground mains proposed to be supplied by this firm, according to specification, consists generally of three lines of pipes laid on one side of the street, and two lines of pipes laid on the other. These pipes to be of earthenware, with patent Archer joints, completely surrounded by Portland cement concrete, and provided with manholes, junctions, boxes, etc. The arc light wires to be drawn into one pipe on each side of the road. The second pipe on each side of the road to be used for the distributing wire, from which the connections to consumers' houses are made; and the third pipe on one side of the road to be used for containing the feeding mains which are joined up at long intervals to the distributing wire on both sides of the street. The advantage of using a separate duct for the feeding wires, as pointed out by these contractors, is that when fresh cables have to be drawn in for extension, no interference will occur to the connections to consumers' premises, as might occur if the feeding wire were drawn into the same duct as the distributing wires, and, in fact, however much the system may be extended, no fresh wires are drawn into the duct containing the distributing wire. The public lighting which these contractors propose to supply includes two semi high-speed Robey engines, running 220 revolutions per minute, provided with an electrical governor, and driving two 55-light Brush machines, supplying current to Brockie-Pell arc lamps, or, as an alternative, Thomson-Houston dynamos supplying current to Thomson-Houston arc lamps, on ornamental lampposts. They also suggest a more expensive lamppost with raising and lowering gear, but involving complications, the adoption of which we cannot see our way to recommend.

The amount of this company's tender for the entire work, buildings excepted, is £33,409.

The Babcock and Wilcox Company

Quote for their own boilers, and for feed-water heaters, which are included in the specification under Specification A. The total amount of their tender is £5,003, which, deducting the amount for the feed-water heaters, quoted at £678, and allowing £22 for carriage and fixing, makes their tender for the boilers alone, say, £4,300.

Messrs. W. T. Goolden and Co.

Tender for alternators, instruments, and transformers. The alternators are of their own make, and of the Kapp type ; the armature revolves, and the same objections apply to it as set forth in the portion of the report referring to Messrs. Johnson and Phillips's tender.

They send no tracing of the switchboards, which are of their own make, and they provide combined hand and automatic regulation gear. The instruments are of their own make, and Cardew. The transformers are of the Goolden pattern, with closed magnetic circuits.

Messrs. Siemens Brothers and Co.

Tender for alternators of their own construction. The drawing does not clearly show whether the armature or field magnets revolve, but we believe the armature revolves, as in the Kapp type machines. The exciters are Siemens continuous-current machines, and are driven by ropes off the alternating shafts. The tender for the alternators, £2,540, is the cheapest on the list. Of the switchboard and instruments, the switchboard arrangement is neatly designed and efficient, but only hand regulation is included. The instruments are not specified, but most probably they are of Siemens Bros.' own make. The meters they propose to supply are of the Aron type, but their price for them is exceedingly high. The system of mains they propose to use is, for the arc lighting single cables, vulcanised rubber, covered, armoured with iron wires, and protected outside again ; and for the private lighting, their concentric conductors, cased with lead and armoured with hoop iron. These cables are being laid in considerable lengths by some of the London electric light companies. They require no conduits or pipes, being sufficiently protected from outside damage by their perfect armouring, and are laid simply in a trench. They send no tracing of the run of the mains, but from the length of cable they specify, it would appear they intend to lay a cable under each sidewalk, and their price for the cables and the laying—£4,990—is a moderate one. At the same time, the method of connecting up consumers to a concentric cable is rather expensive. Their price for the public lighting plant, which consists of their own machines, coupled direct to Willans engines, is the highest on the list. They propose, as an alternative tender, to supply their alternators coupled direct to Willans engines, and with the exciter in this case coupled direct to the armature shaft. As referred to before, in the case of Johnson and Phillips, this combination very considerably economises space, and also allows for a perfect arrangement of steam-pipes, but, as we stated before, we do not propose to recommend you to adopt high-speed engines for the private lighting. Messrs. Siemens Bros'. price for dynamos and engines, and sundries to Specifications A and C combined in this way, is £8,950, a distinctly moderate price, but in this sum they only include one feed-water heater for the three engines, instead of three, as specified, consequently saving on the cost of the feed-water heaters, and also of the pipe arrangements necessary with them. Messrs. Siemens Bros., in addition, tender for a low-tension system, which we refer to later on in this report in connection with the other low-tension systems tendered for.

The Westinghouse Company

Only tender for the complete work, without giving separate tenders for each specification. They also give no particulars as to the make of engines ; the electrical machinery being all of their own make. They also propose to supply the Westinghouse alternating-current arc light system. They recommend, in common with several other contractors, the transformer sub-station system of distribution. Their price for the whole of the works is no less than £55,350, which, by substituting Westinghouse vertical high-speed engines for the horizontal engines, and some other slight differences, might be reduced to £51,340—a price which entirely puts their tender out of the question.

Messrs. Drake and Gorham

Tender for the alternators under Specification C, and public lighting plant under Specification H. They give absolutely no particulars of the plant they propose to supply, and consequently we are unable to criticise their tender.

The foregoing finishes the report on the bulk of the tenders sent in, all of which are for the alternating-current transformer system as specified, but two of those contractors whose alternating current tenders have been considered, have likewise sent in alternative tenders for a low-tension continuous-current system, and these two are Messrs. Crompton and Co., and Messrs. Siemens Bros. and Co., and in addition Messrs. Latimer Clark, Muirhead, and Co. have sent in a tender for a continuous-current low-tension system ; only Messrs. Crompton and Co. accompany their tender with a long report on the advantages of a low-tension system, in which they enumerate what they consider to be many points of advantage in favour of it, the principal ones of which are economy in first cost, and increased economy in working, owing to small losses, but after careful consideration we cannot endorse the claims for advantages on this system made by this company. In the first place, the cost is only cheaper when compared with Messrs. Crompton's own estimate for alternating-current plant, and this is not to be wondered at when this firm quote for alternating-current plant, and appliances made by firms other than themselves, and a considerable portion of this supposed economy is attained by putting in boilers of a smaller steaming capacity and a cheaper type than those specified, and running the public lighting lamps off the private lighting plant, instead of providing separate high-tension continuous-current plant for the public lighting, whilst there is an alarming increase in the price of the mains, which is a point to be seriously considered by you, having regard to the extension of the lighting which is sure to take place. Messrs. Crompton's estimate for the mains laid on Crompton's system for low-tension supply is over £10,000, and although this is a very high figure it is remarkably lower than the tender of Messrs. Latimer Clark, Muirhead, and Co. for the mains alone, for the low-tension supply on their system, which is over £20,000, notwithstanding that this latter company's system would appear to us at least as cheap to construct as Messrs. Crompton's. Again, Messrs. Siemens Bros., who submit an alternative tender for the low-tension system, and who propose to lose a much larger amount of energy than that specified by us for the alternating-current system—namely, 10 per cent., as against 2½ per cent.—require for the low-tension plant and mains £35,000, without boilers and buildings, bringing their total tender, when allowing for these latter, to about £44,000, and this, compared with their own estimate for alternating-current plant, after adding an estimated amount for engines, boilers, transformers, and buildings, not included by them in their tender, shows a saving in first cost in favour of the alternating-current system of about £9,000, and as clearly this difference in price in Messrs. Siemens's tender is largely due to the increased cost of mains, Messrs. Crompton and Co.'s deductions in favour of initial cost are not supported by the tenders of the other two firms, and it must be borne in mind that this firm, unlike Messrs. Crompton and Co., propose to supply plant of their own manufacture for either system. Again, as stated above, you will bear in mind that this project is likely to be but a small beginning to your electric lighting system, and that in the immediate future the size of the station will have to be increased. If the cost of the mains for the low-tension system is so great in the first area, the cost of the mains bringing energy into the second area, which is likely to be outside the first one in the direction of Stephen's-green, would most probably be so prohibitive as to make it better worth your while to put down a second generating station in the second area, and thus reduce the cost of the mains, instead of centralising all your machinery until it reaches a fair size in the one station. Secondly, as regards the question of efficiency in working, the system we recommend for your adoption later on in this report will put the alternating system within a few per cent. of the efficiency of the direct low-tension system, without the large outlay, and (as the distance increases) increasing cost of mains.

Messrs. Crompton and Co. make a statement in their report as to their reason for running the public lighting lamps off the private lighting mains instead of providing separate high-tension plant therefor. They say that the running of arc lamps in series involves the use of complicated appliances, and is liable to get out of order, and that after extended trials in the continental cities in Europe, the low-tension system has been found the most regular and economical system of arc lighting for streets. This we regard as a statement likely to mislead you ; it is beyond question that an overwhelmingly large percentage of the public street lighting by electricity is effected on the series high-tension system, and the use of this system is every day extending ; notably, it is a fact that in American cities using the Edison three-wire low-pressure system for private lighting (identically that proposed by Messrs. Crompton and Co.), the arc lighting in the streets and elsewhere is carried out on one or other of the well-known high-tension series system. We would state that we are of opinion that, taking into consideration the conditions that are likely to be met with for the supply of electricity for private lighting purposes in Dublin, you should accept tenders for the carrying out of the work on the alternating-current system. Referring to the proposition made by several contractors as to the grouping of the transformers in five or six sub-stations, consisting of a small cellar or room in which the transformers are placed, instead of having separate transformers in the houses of each consumer, we are of opinion that you will do wisely in arranging to adopt this system. It will involve an extra initial expenditure on the basis of the lower tenders, of about £3,000, but, as pointed out by Messrs. Gordon and Co., the economy achieved by keeping the transformer always fully loaded will be equal to nearly 25 per cent. of electricity sold ; or, looked at from the other point of view, with a very large saving on your coal bill, which will soon recoup the extra money spent initially. This need not interfere with your progress in accepting tenders, as those contractors from whom you order the transformers and mains can alter their prices to the new conditions, on the same basis as the prices tendered for the old conditions, by means of the schedules attached to their tender.

A. Engine: 18 high pressure, 32 low pressure, 36 stroke, 75 revolutions per minute, made by themselves; design fair but agricultural in type. Boilers by Babcock and Wilcox. Alternators of the Kapp type, by Johnson and Phillips; substantial design, but armature rotates instead of fields, which is objectionable, and exciter coupled. Switchboard arrangements by Johnson and Phillips, well designed, but no mention of method of regulation. Transformers by Johnson and Phillips, Kapp type, good design. Meters: No particulars are given. Mains proposed either Fowler-Waring or Brooks system, neither of which have been tried in this country for high-tension lighting. Public lighting: Semi high-speed engines of their own make. Brush dynamos. Brockie-Pell arc lamps on lampposts of neat design. Proposed dynamos and arc lamps form an excellent combination. General arrangement of steam and exhaust pipes all right.

B. Davey-Paxman Engines: No particulars. Dynamos: No particulars, probably Goolden type. Exciters uncoupled, speed 380 revolutions. Instruments of their own type. Goolden transformers. Meters and mains: No particulars. Public lighting: No particulars.

C. This tender is identical in every respect, excepting price, with that of Messrs. Hornsby and Son, above described.

D. This tender is identical in every respect, excepting price, with that of Messrs. Laing, Wharton, and Down.

E. Engines: Specification A, no particulars. Alternators: Thomson-Houston, speed 680 revolutions; exciters uncoupled. Switchboards: Thomson-Houston. Instruments by Elliott Bros. Transformers and meters: Thomson-Houston. Mains and distribution not described. Public lighting: Thomson-Houston dynamos. Engines: No particulars.

F. Engines by Combe, Barbor, and Combe, of Belfast. Cylinders, 14in. and 22in.; stroke, 36in.; speed, 90 revolutions. Boilers: Babcock and Wilcox. Dynamos: Mordey-Victoria, 400 revolutions. Exciters (Victoria) uncoupled, guaranteed efficiency, 90 per cent. Switchboard by Brush Company, with Nalder or Evershed instruments. Hand and automatic regulating apparatus. Sir William Thomson galvanometer and Wheatstone bridge. Mordey-Victoria transformers. Ferranti meters. Callender-Webber system of mains. Public lighting by three Brush dynamos, and engines by Davey, Paxman, and Co. Semi high-speed engines; cylinders, 7in. and 11in. diameter, 8in. stroke.

G. Engines: No maker stated. High-pressure cylinder, 17½in. diameter; low pressure, 27½in. diameter. Stroke, 36in. Speed, 80 revolutions. Dynamos (exciters uncoupled) Lowrie-Hall system, 350 revolutions. Regulating apparatus: Lowrie-Hall; automatic and hand regulation in addition. Well-designed switchboard, House-to-House system. Instruments by Thomson, of Thomson and Cardew type. Transformers of the Lowrie-Hall type. Meters: Lowrie-Hall, Ferranti, or Shallenberger; Mains: Cast iron with junctions and surface-boxes, vulcanised rubber insulation. Engines for public lighting, 7¼in. and 11¼in. diameter; 10in. stroke; speed of 220 revolutions, no maker's name stated. Dynamos for arc lighting in series. Dynamos with automatic current regulation, 800 revolutions per minute. Brockie-Pell arc lamps. Lampposts of plain design.

H. Engines of their own make. Cylinders (high pressure) 12in., and (low pressure) 22in.; stroke, 24in. Speed, 90 revolutions. Alternators: Kingdon type of their own make. Instruments of their own make, but non-inclusive of synchronising appliances. Transformers of the Brush make. Meters of the Ferranti-Wright type. Mains: Cast-iron pipes and vulcanised rubber cables, Silvertown make. Public lighting: Engines of their own manufacture. Brush dynamos supplying current to Brockie-Pell lamps on ornamental cast and wrought iron lampposts. Only two sets of public lighting plant of sufficient size to do all the work between them have been included, instead of three as specified.

I. Engines by Pollitt and Wigzell. High pressure, 17½in.; low pressure, 28½in.; stroke, 42in. Boilers: Excelsior or Mills. Alternators by Goolden and Co.; speed, 400. Exciters of their own make, uncoupled. Regulating apparatus operated by hand; no mention of makers of instruments. Transformers of the Statter type. Meters of the Aron type. Mains: Vulcanised rubber cables laid in cement concrete conduits. Public lighting engines by Davey, Paxman, and Co. Generators of their own make, with Statter's constant-current regulating apparatus. Arc lamps, Crompton-Crabbe, mounted in lanterns on lampposts of exceedingly handsome design.

K. Engines: No particulars. Boilers: Babcock and Wilcox. Alternators: Their own make, with their own exciters uncoupled. Hand regulating apparatus, with instruments by Sir William Thomson, Cardew, and Elliott Brothers, but no recalibrating apparatus included. Transformers of their own make.

L. Engines by Fowler and Co., Leeds. High-pressure, cylinder, 17½in.; low-pressure, 27½in.; stroke, 36in. Flywheel, 15ft. diameter; feed-water heaters by Kirkaldy and Co. Babcock and Wilcox boilers. Steam-pipes by Worthington Pump Company. Alternating-current dynamos of the Statter patent type; stationary magnets, revolving armatures, speed under 400 revolutions. Exciter coupled direct, very complete arrangements, automatic and hand regulation gear. Switchboards: House-to-House Company's type. Instruments by Sir William Thomson, Cardew, and Elliott Brothers. Transformers of the Statter type in water-tight iron casings. Meters of the Ferranti type. Mains highly insulated, vulcanised covered cables with junctions. Public lighting engines: The Gwynne or Allen type compound, 220 revolutions per minute, continuous current. Dynamos: Statter type, with automatic regulation. Arc lamps: Statter type in lanterns.

N. Engines by Robey and Co., with automatic trip expansion gear: High-pressure cylinder, 17½in.; low-pressure, 30in.; stroke, 40in.; speed, 75 revolutions. Boilers: Mills or Excelsior.

Dynamos: Lowrie-Hall-Ellwell-Parker manufacture, 350 revolutions. Exciter uncoupled. Switchboards same type as used by Metropolitan Electric Supply Company, Manchester-square station. Instruments by Goolden and Cardew. Hand regulating apparatus. No synchronising appliances. Mains in earthenware pipes, with patent Archer joints, and highly-insulated vulcanised rubber cables, arranged either on the sub-transformer system or as per specification. Meters of the Westinghouse type. Public lighting engines by Robey and Co., vertical side by side compound, 220 revolutions per minute, driving either Brush or Thomson-Houston dynamos, feeding either Brockie-Pell or Thomson-Houston lamps.

N. Quote for boilers and feed-water heaters only.

O. Alternators of their own manufacture. Instruments of their own and Cardew's manufacture. Transformers of their own make.

P. Alternators of their own type, speed 400 revolutions per minute. Exciters uncoupled, and rope-driven. Switchboards by themselves. Instruments: No particulars. Aron meters. Siemens' single and concentric cables. Public lighting: Siemens machines coupled to Willans, engines running Siemens arc lamps on ornamental posts.

Q. Engines; 15in. high pressure, 24in. low pressure, 36in. stroke; 90 revolutions. Alternators: Westinghouse. Exciters: Uncoupled. Instruments: Westinghouse. Meters; Westinghouse. Mains: Cast-iron pipes and vulcanised rubber, highly insulated cable. Public lighting: Westinghouse alternating-current system. No particulars of engines.

S. Alternators: No particulars. Public lighting plant: No particulars.

APPENDIX C.

68, Victoria-street, Westminster, S.W.,
London, 1st August, 1890.

To the Electric Lighting Committee of the Dublin Corporation.

Proposed Dublin Electricity Supply, 1890.

Gentlemen,—In accordance with instructions received from the town clerk and borough surveyor, I have gone carefully into the question of the electricity supply for public lighting purposes in the compulsory area embraced in your license for public lighting, and the supply for private lighting purposes embraced in your license for private lighting, and I now have pleasure in enclosing you herewith two specifications, estimates, map, and plans.

The specifications are for two schemes—one on the assumption that a central station is put down with sufficient plant to provide current for 80 arc lamps of about 1,000 c.p. each, and 3,000 incandescent lamps of 16 c.p. each; the other on the assumption that power is provided for the same number of arc lamps for the public lighting, but with sufficient power and enlarged mains for the supply of current to 5,000 lamps of 16 c.p. each for the private lighting.

You will notice by the estimates, which have been very carefully drawn up by me, that the cost of the larger station, mains, etc., is about £50,000, and of the smaller station, mains, etc., about £37,000. The estimate for the smaller station is naturally higher in proportion than for the larger station, as many of the works would be identical for both to allow for the extension of the smaller station should you determine to start with that.

Both specifications have been drawn up in a manner that, while stipulating the conditions that have to be fulfilled by the contractor, a free hand is left him in suggesting the details of his own scheme, and I have done this in accordance with your instructions.

The Fleet-street site would be well adapted for the carrying out of either scheme, and one of the plans accompanying this, and intended to go with the specifications, shows the arrangement of the plant I would propose for either scheme.

The large map accompanying this, and which shows in one colour the compulsory area, and in another the extension you propose to make, is marked with the run of the mains and the distribution of lights for both public and private purposes, as you will probably find to be the case in actual practice.

The number of lamps and their arrangement allowed for the public lighting is, in my apinion, amply sufficient for the perfect illumination of those streets, and sufficient amount of spare plant is allowed to effectually guard against chances of a breakdown. The circuits are so arranged that each alternate lamp is on a different circuit, and the temporary extinction of one circuit would not interfere with the public convenience.

I have provided for the private lighting being carried out on the alternating-current transformer system, which I consider to be the best for the supply of current for private purposes in Dublin, and I believe from what you have seen of the lighting by electricity at present in use in the United Kingdom, you have satisfied yourselves on this point.

The following are my estimates of the probable revenue and costs for working for the two installations—viz.:

Cost of Maintenance of a Central Station for 80 Public Lights, 1,000 c.p. each, and 3,000 Private Lights of 16 c.p. per annum.

Capital cost about £37,000.

Labour—Superintendent		£300	0	0
4 engine drivers	per week, 30s.	312	0	0
2 assistants	,, 20s.	104	0	0
4 stokers	,, 20s.	208	0	0
4 linesmen	,, 30s.	312	0	0
1 fitter	,, 40s.	104	0	0
1 assistant fitter	,, 30s.	78	0	0
2 meter attendants	,, 25s.	130	0	0
3 arc lamp trimmers	,, 20s.	156	0	0
Drawing and office expenses	,, 60s.	156	0	0
Coal for 840,000 h.p. hours, at 4lb. per h.p. hour, about 1,500 tons, at 18s.		£1,350	0	0
Oil, water, and waste, 15 per cent. off cost of coal		202	10	0
Repairs and sundry materials, say, 5 per cent. on £37,000		1,850	0	0
Carbons for 320,000 arc lamp hours, at ¾d. per lamp per hour		1,000	0	0
		£6,262	10	0

Allowing that on an average 10 per cent. of the 3,000 lamps are burning day and night, 129,600 Board of Trade units will be sold on this account; and that the balance of the 3,000 lamps are burning on an average 1,000 hours per annum, 162,000 Board of Trade units will be sold on this account; or together 291,000 Board of Trade units; that at 7d. per unit will yield a gross revenue of £8,487. 10s., from which the annual maintenance charges of £6,262 have to be deducted, leaving a net revenue of £2,221.

You will, however, notice that nothing has been allowed for the cost of the public arc lighting, and it is fair to assume that this will cost you at the rate of £20 per annum for each arc lamp, or for the 80 lamps, £1,600, and this has to be added on the net revenue of £3,821.

Cost of Maintenance for a Central Station for 80 Public Lights of 1,000 c.p. each, and 5,000 Private Lights of 16 c.p. each per annum.

Capital cost about £50,000.

Labour—Superintendent		£300	0	0
5 engine drivers	per week, 30s.	390	0	0
3 assistants	,, 20s.	156	0	0
5 stokers	,, 20s.	260	0	0
4 linesmen	,, 30s.	312	0	0
2 fitters	,, 40s.	208	0	0
1 assistant fitter	,, 30s.	78	0	0
3 meter attendants	,, 25s.	195	0	0
3 arc lamp trimmers	,, 20s.	156	0	0
Drawing and office expenses	,, 80s.	208	0	0
Coal for 1,160,000 horse-power hours, at 4lb. per horse-power hour, about 2,080 tons, at 18s.		1,872	0	0
Oil, water, and waste, 15 per cent. of cost coal		280	10	0
Repairs and sundry materials, say, 5 per cent. on £50,000		2,500	0	0
Carbons for 320,000 arc lamp hours, at ¾d. per lamp per hour		1,000	0	0
		£7,915	10	0

Allowing as before that on an average 10 per cent. of the 5,000 lamps are burning day and night, 180,000 Board of Trade units will be sold on this account; and that the whole of the 5,000 lamps are burning on an average 1,000 hours per annum, 300,000 Board of Trade units will be sold on this account, or together 480,000 Board of Trade units; that at 7d. per unit will yield a gross revenue of £14,000, from which the annual maintenance charge of £7,915 has to be deducted, leaving a net revenue of £7,085.

As before, the cost of the arc lighting—viz., £1,600—must be added to this, making the real net revenue £8,685.

Of course the approximation of the revenue depends upon the actual amount of light that will be consumed, but I think the figures I have given you, and which are founded on the results of actual working, may be relied upon, as there can be little doubt that lighting will be taken up vigorously by the citizens of Dublin.

I remain, Gentlemen, yours faithfully,

E. MANVILLE, per S.W.

COMPANIES' MEETINGS.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY.

The twenty-seventh ordinary general meeting of this Company was held at the Cannon-street Hotel on Thursday, the chairman, Mr. S. W. Silver, presiding

The **Secretary** (Mr. W. J. Tyler) having read the notice convening the meeting,

The **Chairman** said the report (*vide* our last issue) had been in their hands, and he presumed they would take it as read. He would rise to move that the report be received and adopted. In doing so, he would remark that since they had the pleasure of meeting the shareholders, the works had been well employed, and they had found ample requirements for all their capital. The report showed the result to be very satisfactory; and this notwithstanding the keen competition met with in obtaining orders, and the price of the raw material having considerably advanced. This he need not say had affected the rate of profit. In the submarine telegraph branch they had manufactured during the year upwards of 2,000 miles of cable, and he would remark that the item referred to under the head of stock as cable on account of contracts, had just been successfully laid by their staff on board the "Silvertown," off the west coast of South America. The day-by-day trade of the Company had increased, being over half a million for the year. He was glad to say that the prospects for this year were as satisfactory, and they had several cable contracts in view. These remarks applied equally to Persan as to Silvertown. In asking them to adopt the report, he would recommend an addition being made to the reserve fund, which supplied them with the sinews of war, and took the place of a considerable increase which would have to be made in the capital of the Company. The result of this (supposing the capital to be increased), he need not remind them, would seriously affect the dividend by increasing the number of those who shared it. The freehold buildings and the machinery had been maintained and were in the highest state of efficiency. They had in their operations at Silvertown evidence that capital and labour, when combined with judgment and well-directed energy, could be made to render a fair return to the investor for his money, and a just remuneration to the employed. He then moved the adoption of the report and accounts, and the payment of a dividend of 10s. per share, free of income tax, payable on and after the 20th inst. (to-day).

This was seconded by **Mr. A. W. Jarvis, M.P.**, and adopted, after some discussion.

Resolutions were then carried re-electing Messrs. Bannatyne and Henderson as directors, and Mr. Weise (of Turquand, Young, and Co.) as auditor.

COMPANIES' REPORTS.

CITY AND SOUTH LONDON RAILWAY.

The report of the Directors for the half-year ending December 31 states that the railway has been completed, and was opened for public traffic on December 18 last. Since that date a service of trains, running at intervals of about five minutes, has been maintained, and although there have been a small number of occasional delays from the failure of engines and other causes, there is every reason to be satisfied with the use of electricity as a motive power, and when the various improvements suggested by experience are all carried out it is anticipated that the line will prove one of exceptional safety and comfort, and will be worked with economy and regularity. During the short time the railway has been working the average number of passengers carried has been about 15,000 per day, but as the weather improves and the line is better known this number will no doubt steadily increase. It has been found in working such a rapid service that the siding accommodation provided is insufficient, and arrangements are now in progress for the construction of additional sidings at the Stockwell terminus, which will add greatly to the facilities for working the line. The accounts for the past half-year have been made out in the form previously adopted, but as the Company is now recognised as a railway, the accounts in future will be rendered in the form prescribed by the General Railway Acts. As the line was only opened a few days before the close of the half-year, it has not been thought necessary to create a separate revenue account for that short period.

CITY NOTES.

City and South London Railway.—The receipts for the week ended February 14 were £702.

Brazilian Submarine Telegraph Company.—The receipts for the week ended February 13 amounted to £5,538.

Commercial Cable Company.—The Company's general offices in London have been removed from 29, Threadneedle-street to 18, Bishopsgate-street Within, E.C.

Western and Brazilian Telegraph Company.—The receipts for the week ended February 13, after deducting 17 per cent. payable to the London Platino-Brazilian Company, were £4,493.

Woodhouse and Rawson.—This week Woodhouse and Rawson United, Limited, invited applications for 20,000 ordinary £5 shares and 10,000 preference £5 shares, entitled to a preference as to capital and to 7 per cent. preferential cumulative dividend per annum, together with a further 1 per cent. in every year in which the ordinary shares have received a dividend of 10 per cent. or upwards. There were also £100,000 5½ per cent. 1891 debenture stock (part of a total issue of £200,000), which is created partly to pay off the existing 6 per cent. debentures, and partly to pay off the balance of the sum deposited with the Company as a guarantee fund. The list closed on Wednesday.

PROVISIONAL PATENTS, 1891.

FEBRUARY 9.

2334. **Improvements in and relating to electrical communicators for use on public vehicles and the like.** John William Eyre and Charles Graham, 389, Kennington-road, London.

2360. **Improvements in or relating to accumulator plates.** Henry Tyrer Cheswright, 323, High Holborn, London. (Complete specification.)

FEBRUARY 10.

2417. **A new or improved voltmeter and ammeter.** Joseph Matthews and George Birrell Cruickshank, 7, Staple-inn, London.

2418. **Improvements in electric accumulators or storage batteries.** Joseph Matthews and George Birrell Cruickshank, 7, Staple-inn, London.

2431. **Improvements in safety appliances applicable with switches, fusible cut-outs, or other electrical circuit-breakers, for the prevention of flashing or sparking across from one conducting part to another.** John Alexander Colquhoun, 6, Lord-street, Liverpool.

2446. **Improvements in or connected with means or apparatus employed in electrolysis.** James Yate Johnson, 47, Lincoln's-inn-fields, London. (George D. Davis, United States.)

FEBRUARY 11.

2471. **The manufacture of hydrolised lead cells for electrical or storage batteries.** Thomas William Bush and Matthew Doubleday, Loughboro'-road, West Bridgford, Nottingham.

FEBRUARY 12.

2518. **An improved method of depositing copper or other metals by electrolysis, with the object of refining it or them, or of recovering the precious and or other metals contained in or alloyed with the metal under treatment.** William Gibbings, 23, Island-road, Garston, Lancashire.

2522. **Improvements in attachments or fittings for electric light sliding pendants, electroliers and stand, and other extension lamps.** William Reuben Lane and John Cottrell, 6, Livery-street, Birmingham.

FEBRUARY 13.

2642. **Improvements in telephone receiving instruments.** Ernest Jules Pierre Mercadier, 55, Chancery-lane, London.

2654. **Improvements in primary batteries** Sir Charles Stewart Forbes, Baronet, 21, Finsbury-pavement, London.

2664. **Improvements in machinery for cutting coal or other minerals, driven by electricity.** Llewelyn Birchall Atkinson and Claude William Atkinson, 1, Queen Victoria-street, London.

FEBRUARY 14.

2677. **Improvements in meters for measuring, registering, and recording electrical currents, in part applicable to other measuring and recording instruments.** Charles Algernon Parsons, 13, Temple-street, Birmingham.

2689. **An improved ceiling rose, or connector for electrical circuits, and for the suspension of electrical fittings, and similar purposes.** Edward William Lancaster, Albert Works, Graham-street, Birmingham.

2706. **Making joints and connections in concentric cables, or mains for conveying electric currents.** Arthur West Heaviside and Robert Cattley Jackson, 7, Grafton-road, Whitley, Northumberland.

2714. **Improvements in electric lighting and for other like purposes.** Robert James Ray, 85, Gracechurch-street, London.

2732. **Improvements in flexible supports for electric lamps.** William White, 28, Southampton-buildings, London.

NOTES.

Rawtenstall.— The surveyor has been requested to prepare estimates for more light.

Orleans.—The subway station of Orleans is to be entirely lighted by electric light upon the Ganz system.

Bideford.—The question of better lighting the town of Bideford is occupying the attention of the Town Council.

Folkestone.—The Lighting Committee of Folkestone are resorting to arbitration to fix the price of their public lighting by gas.

Tivoli.—One of the last acts of Signor Crispi was, we understand, to issue a decree for the utilisation of part of the celebrated Falls of Tivoli for public electric lighting.

Hull.—The deputation from Hull which visited Bradford has reported very favourably; advise the Corporation to undertake the supply, but are unable as yet to definitely recommend a system.

Gordon's College, Aberdeen.—The committee have agreed to purchase a gas engine for £235, and enquiry was ordered to be made as to the relative cost of lighting by gas and by electricity.

Endolithic Ivory.—The Endolithic Ivory Company, Limited, were awarded the only prize medal and diploma for address tablets and switchboard labels at the exhibition lately held in Edinburgh.

Stratford-on-Avon.—A handsome new post office will be erected at Stratford-on-Avon this year. As it is usual for new post offices to have the electric light, plant will probably be required here.

Barking.—The public lighting of Barking, Essex, is carried out by means of oil. A deputation recently asked the Local Board to introduce gas. While they are about it electric light might be applied.

Heckmondwike (Yorks.).—At the last meeting of the Barnsley Town Council it was announced that the Westinghouse Electric Lighting Company were not willing to undertake the lighting of Heckmondwike.

Dungarvan.—The wretched state of the lighting of Dungarvan, Waterford, now carried out by oil, is exciting the attention of the Town Commissioners, who are inviting tenders for other means of illumination.

Brush Dividend.—The Brush Electrical Engineering Company have issued warrants for an interim dividend on the preference shares for the half-year ended 31st December last, at the rate of 6 per cent. per annum.

Paris Concessions.—An amalgamation under direction of the chief bank of Paris—something similar to what has taken place in the City of London—is said to be expected between the various companies holding concessions for lighting the various sections of Paris.

Electricity in Physiology.—Before the Royal Society, yesterday, the Croonian lecture was delivered by Mr. F. Gotch and Prof. Victor Horsley, F.R.S., "On the Mammalian Nervous System, its Functions and their Localisation Determined by an Electrical Method."

Durban.—Durban has still to depend upon oil lamps for its illumination, but with this state of affairs dissatisfaction is now being freely discussed. The question to be decided is, and it is being argued with some spirit in the local newspapers: Is it to be gas or electricity?—*Gas World.*

Chiswick.—The Works Committee of the Chiswick Local Board report that with regard to the amended provisional order for Chiswick electric lighting, the only clause that had been inserted on objections made was the saving clause of the Thames Conservancy, to which the Board did not object.

Water at St. James's.—The borings for water in Mason's-yard for the St. James's Electric Light Company, have proved extremely successful, and the yield is now over a million gallons a week. The parish intend to imitate the example, and use the water for baths and for cleaning the streets.

Marseilles.—The Gas Company of Marseilles are erecting several central stations for electric light, the power for which is provided by means of large gas engines which are to be used to charge accumulators. The company is wise in its generation—dividends from both gas and electricity may be now expected.

Westinghouse Company.—The financial troubles encountered by the American Westinghouse people is, according to the latest papers, now over, and a brisk demand is maintained for Westinghouse stock. The recovery of prices is good for all, as the shares of the other electric companies were beginning to decline out of sympathy.

Bedford.—The Corporation of Bedford, having obtained a provisional order, invite tenders, as will be seen from their advertisement elsewhere, for the public lighting of the borough for a term of years, at a price per lamp, the contract carrying with it privileges for supplying private lighting and power. Tenders will be received until March 31 next.

Portsmouth.—The Portsmouth Electric Lighting Committee have decided to recommend the Town Council to take the management of the electric lighting works in the borough, instead of leasing the powers granted by the Corporation to a private company. The Council is asked to adopt the low-tension system, to avoid the danger of overhead wires.

Air Ship.—Messrs. Siemens and Halske have undertaken the electrical apparatus for an airship, which is to be exhibited at the Frankfort Exhibition in the shape of a large dirigible balloon for carrying 10 persons. The balloon will be connected by a telephone, and the gas will be generated by electrolysis, the arrangements being suitable for war balloons.

Lynton.—The electric light, which has been entirely absent from Lynton and Lynmouth since Christmas, reappeared at Lynmouth last week, and has been satisfactory there, but has failed to reach Lynton. An electrical engineer has recently tested the wires, and reports that the joints are in a very defective state. The matter is being attended to with all speed.

Electrically Welded Projectiles.—The Thomson Electric Welding Company have decided to organise the American Projectile Company, with a capital of half a million dollars, to manufacture electrically welded shells out of seamless tubes and solid pointed ends. Large Government contracts are secured, and the buildings and plant will be ready within two months.

Cambridge University.—The new Professor of Engineering at Cambridge (Prof. Ewing), is already making extensions at the university in the interest of his department. A steam engine and other apparatus necessary for a laboratory of engineering and applied electricity are to be supplied at a cost of £500, and a second demonstrator is to be appointed, at a stipend of £150 per annum.

Cantor Lectures.—The third and last of Mr. Kapp's lectures on "The Electric Transmission of Power" will be given before the Society of Arts on Monday, 2nd March, at eight o'clock. Syllabus of Lecture III.: Limit of Dis tance to Direct-current Transmission—Alternating-current Transmission—Synchronising Motors—Ferrari's Motors—Motors for Small Powers—Electric Machine Tools.

Hyde Park Corner.—The high-class lighting at Hyde Park Corner is costing the Gas Light and Coke Company £160 more a year than it receives for it from the St. George's Vestry. The Vestry objects to pay this sum, but it wants to retain the light. The electric light company has refused to take the place of the gas company, and the Vestry has offered the gas company £50 a year to continue the lighting.

Huddersfield.—At a monthly meeting of the Huddersfield Town Council held last week, a report which had been presented by the Electric Lighting Sub-Committee, with respect to the different systems of electric lighting which had been investigated, was adopted, and the town clerk received instructions to write to the town clerk of Birmingham for information with respect to the system of electric lighting adopted in that city.

Electric Fire at the Czar's Palace.—On the 18th inst. the Czar, according to a Reuter's telegram, being in his Anitchoff Palace, St. Petersburg, noticed a smell of burning, and saw clouds of smoke coming from the apartments of the Empress. The flames were subdued by the firemen after destroying some valuable paintings, statues, and tapestry. The fire is rumoured to be owing to the defective fixing of electric light wires.

Molecular Resistance.—M. P. Joubin has undertaken researches upon the physical properties and the molecular constitution of simple metallic bodies, which he divides into two groups—diamagnetic and magnetic metals. According to the results he has obtained, all the physical properties of the metallic bodies of the same group would depend exclusively on the distance of their molecules, the two groups being distinguished by the relative conductivity of their molecules.

Telephoning Telegrams.—The Western Counties and South Wales Telephone Company have for some weeks made arrangements, at the request of the Plymouth Chamber of Commerce, that subscribers can call upon No. 199, the Plymouth Post Office, and dictate their telegrams, which are thus sent direct—with great saving of time and trouble—the only condition being that the subscriber must have a suitable deposit at the post office against the cost of such telegrams.

Newport (Mon.).—At the meeting of the Newport Town Council on Monday last the Mayor moved a formal resolution that the Council approve and authorise the application for a provisional order to supply electricity within the borough. Mr. Howell thought the opinion of the ratepayers should be taken before £30,000 was spent on electric light. It was explained that the Corporation had no choice but to take powers, otherwise a private company would come and pull up the streets. The proposal was carried.

Electricity to the Rescue.—A destructive fire broke out last Sunday at Maids-Moreton Lodge, near Buckingham, the residence of Baroness Kinloss and Captain Luis Morgan Grenville. The butler gave the alarm and Baroness Kinloss and family were removed from the building, and the servants had a narrow escape, the residence at this time being full of smoke. Captain Morgan had recently had the place lighted by electricity, and, this being turned on, the inmates by its aid were able to escape.

Electrical Purification of Sewage for Paris.—There are now in Paris, points out the *Bulletin Internationale de l'Electricité*, central stations representing 26,000 h.p. not utilised for the greater portion of the day, and it would seem that the expense would be less to the ratepayers if the city machinery were to be used for the purification of the sewage, the effluent of which could be simply run back into the Seine, instead of the costly scheme proposed of taking the sewage to irrigate Normandy.

Cleckheaton Town Hall.—At a meeting of the Cleckheaton Town Hall Committee it was unanimously resolved to accept the recommendation of a sub-committee to light the Town Hall premises by electricity. This would involve an extra initial outlay of about £500, but it is thought that electricity would be preferable alike in point of cleanliness, health, and general suitability, and that it would ultimately save a good deal of expenditure in cleaning and redecoration. The proposal yet requires the sanction of the Local Board.

Birmingham Inspectorship.—With reference to the report of the Birmingham committee on electric testing, given in another column, the committee have ascertained that Mr. Henry Lea (Messrs. Lea and Thornbery) is willing to discharge the duties of electric inspector for 12 months at a salary of £150, and they recommend that he should be appointed. The committee are conferring with Mr. Lea as to the position, etc., of the testing station, and the fees to be prescribed as the fees to be taken by the inspector and by him paid to the credit of the borough rate.

Madrid.—The Madrid Chamber of Deputies will shortly be lighted by electric light from its own installation. The Senate House will, however, be supplied from the company's mains. The inhabitants of Madrid seem to be much in favour of the electric light, as orders to be connected come in by great numbers every day. Unfortunately, it is stated, many of them do not remain customers more than sufficient time to just be able to say they have had the light, on account of the high price—1s. 3d. per 1,000 watt-hours—that the company at present charge for the current.

Paris.—The celebrated clothing store in Paris which goes by the honoured name of "Old England" (amusingly pronounced something like "Oll Donglong"), has recently been lighted throughout by electricity, by means of Cance arc lamps. The installation comprises 14 lamps taking eight amperes and 22 lamps of six amperes, enclosed in small opal glass globes, besides 50 16-c.p. incandescent lamps. The current is supplied from mains of the Place Clichy, which are run on the Siemens five-wire system. The installation is provided with an elaborate switchboard and protective appliances.

Obituary.—It is with exceedingly great regret that we hear of the loss sustained by Mr. W. T. Glover in the death of his wife at the early age of 36 years. Mrs. Glover passed away after a protracted illness on the 23rd February, and will be buried to-day at St. Paul's Church, Kersal. Many of the numerous friends of Mr. Glover have participated in his hospitality at Moorhurst, and will sympathise with him in his hour of trial, knowing the great interest taken by the late Mrs. Glover in all that concerned the welfare of electricity and in the doings of the prominent members of the industry.

Definitions.—Lord Salisbury, besides being an able statesman, is a scientist, and often a witty one. This characteristic was amusingly illustrated in his speech to celebrate the jubilee of the Chemical Society on Wednesday, when he gave some novel definitions of modern science. "I should say," said his lordship, "that astronomy is largely the science of things as they probably are. Geology consists mainly of the science of things as they probably were. Chemistry is the science of things as they actually are." To this we may add that electricity is the science of things as they probably will be.

Subway for Submarine Cables.—In addition to Sir Edward Watkin's Channel Tunnel scheme, and Sir Edward Reed's tube tunnel, a third plan has been projected, and has been submitted for the consideration of the Postmaster-General. This consists of a tunnel bored much on the lines of the South-Eastern project, but the bore not to be of greater magnitude than necessary to convey the mails, and find room for the telegraph wires, thus avoiding the expense of cable lines. It is claimed that the adoption of this scheme would save two hours in the transmission of continental mails, whilst it would add considerably to the certainty of the service.

Electric Tramway at Acton.—The Acton Local Board at their last meeting had before them a letter from the secretary of the West Metropolitan Tramway Company, asking permission to apply electricity as the motive power of this company's cars on the portion of their system under the control of the Board, and stating that the slot was now entirely dispensed with, and that the Board could see the system in full operation at any time. The clerk read a copy of the agreement between the Hammersmith Vestry and the company. Mr. Lewsey proposed that the sanction of the Board be given, subject to the same conditions being carried out as proposed between the Hammersmith Vestry and the company, suitable to the case of Acton. The details were left to the Works Committee.

Liverpool Assistant Electrician.—Owing to the rapid increase in the amount of electric testing and inspectional work carried out by the Liverpool inspection department, which has followed upon the extended operations of the Liverpool Electric Supply Company, Limited, a general assistant to the Corporation electric inspector has been appointed. After some discussion, Mr. Herbert James Roscoe was awarded the situation subject to the usual provisions as to superannuation, etc., and was instructed to commence duties on the 11th inst. Mr. Roscoe was, until the time of his appointment, in the employ of the Liverpool Electric Supply Company, Limited, a company which has probably a larger output than that of any other using the simple parallel system of distribution at low pressure.

Ferranti Mains.—The Highways Committee of the London County Council have considered a notice from the London Electric Supply Corporation of intention to lay trunk mains across Cockspur-street and into Red Lion-yard, where the company has a distributing station. There appears to be no objection to what is proposed, and they recommend that the sanction of the Council be given to the laying of the trunk mains referred to upon condition that the company do give two days' notice to the Council's chief engineer before commencing the works; that the mains, where laid under the footways, shall be kept 2ft. below the underside of the paving, and where they cross the carriageway at the same depth below the concrete, or if this be found to be impracticable, that the mains be protected from mechanical injury to the satisfaction of the Council's chief engineer.

City Lighting.—A meeting of the City Commission of Sewers was held on Tuesday at Guildhall. The Streets Committee laid before the Commission a letter from the Board of Trade intimating that they were satisfied that the Brush Electrical Engineering Companies were in a position to discharge the duties and obligations imposed upon them by the City of London (Brush) Electric Lighting Order, 1890. Mr. Morton, M.P., asked whether the Commission were dealing with the two companies with whom they had contracted in regard to the electric lighting of the City, or with the company of which the Lord Mayor was chairman. The chairman said that, as he understood the matter, they had nothing whatever to do with the latter company. In a discussion which followed, it was stated that the company hoped to be able to light Queen Victoria-street and Cornhill within the next two months.

Copenhagen.—The contract for the establishment of an electric central station for Copenhagen, which was obtained by Messrs. Siemens and Halske, will be commenced this spring. It is to be ready for next winter's lighting. The station is to be for 14,000 16-c.p. lamps, the site being right in the centre of the town. The plant will comprise seven multitubular boilers and three steam engines. Each of the latter will drive two compound dynamos, coupled in sets of two in series. The total capacity is 611 kilowatts. The mains will form a three-wire network with feeders. From the station to the centre of the distribution the loss will be 28 volts, and from each distributive centre to the last lamp another three volts. The lamps will be 110-volt lamps, consequently the total voltage will be 251 volts. The machinery will be used during the daytime to charge Tudor accumulators, capable of giving a current of 250 amperes. Other batteries will be added as the demand increases.

Swansea.—The Electric Lighting Committee of the Swansea County Council reported that a communication from Messrs. Crompton and Co. was read, stating that they could only undertake the work of electric lighting on a 21 years' lease; the schedule of prices to be subject to revision at intervals of seven years. The committee, however, were not prepared to entertain those terms. The town clerk was directed to invite the following gentlemen to personally appear before the committee, and give the committee, gratuitously, the benefit of their advice and experience in electric lighting: Mr. J. C. Howell (of the Crompton-Howell Company), Llanelly; Mr. Alex. Sinclair, Swansea; Mr. J. S. Brown, Swansea. Mr. Sinclair and Mr. Brown attended, and the question of public street lighting by electricity was discussed, and the committee recorded their thanks for the information given by the above-named gentlemen. Mr. J. C. Howell, being absent from the country, was unable to attend.

Petitions.—The Brush and other electrical companies have presented petitions to the London County Council against the General Powers Bill; and from the various railway companies and the National Telephone Company against the London Overhead Wires Bill; also against the various electric subway railways—Central London, South London, and South Kensington—by all manner of authorities, from the Dean of St. Paul's and the City Guilds Institute, New River Company, Bank of England, to the Duke of Portland and the Vestry of St. Luke's. One of the most amusing of these was from some petitioners along the route, who object to the "whistling of the engines," that might disturb them—forgetting, or not knowing, that the locomotives were 50ft. under ground. The usefulness of these electric railways to relieve the enormous and growing traffic of London streets is, however, becoming gradually realised, and it is only probable that most of these petitions will be dropped without challenge.

Northampton.—Mr. Crompton, who is the consulting engineer to the Northampton Electric Company, has inspected the works at Angel-lane, and tried the plant working at full load. This trial was in every way satisfactory, showing that the work has been done well. The directors who were present at the trial were pleased to find that there was so little vibration from the machinery as not to be felt at all outside the building, especially as there has been some talk of possible annoyance to neighbours from this cause. The first portion of mains for the supply current will be completed in a few days, the culverts for these having been constructed by Messrs. Green Bros., under the superintendence of Messrs. Crompton and Co.'s engineer, who put in the copper mains. This part of the work, which is at any time a tedious process, and fraught with inconvenience to the public, has been much retarded by the late prolonged frost. The residents will now, however, be rewarded by the facility for both light and power afforded by the electric light company along the route. The directors have appointed Mr. B. R. Beale, A.M.I.C.E., who has superintended the erection of all the company's works, to be their chief engineer.

Storage Cars Replace Overhead Lines.—In the present state of accumulator traction in England, it may be interesting to note that a contract has been made with the Accumulator Company for the equipment of the new branch of street railroad in Washington with six storage battery cars. This tramway company was one of the first street car roads in the United States to adopt electricity as a means of propelling its cars, and the Thomson-Houston system of trolley wires was installed there several years ago. Congress, however, will not permit the railway company to erect any more trolley poles, particularly in the heart of the city, and this storage battery system has been adopted. The Edco system, which is to be adopted, is the invention of Mr. W. W. Griscom, the president of the Electro-Dynamic Company, of Philadelphia, the initials of which title serve to form the title word of the system. The cars are being manufactured by the Brill Company, of Philadelphia, and will be lighted by electricity, equipped with the Edco system of motors and gearing, the gearing running in oil, with dust-tight covers for motors, and with a number of 23M type accumulators, designed to give an average speed of eight miles an hour and a maximum speed, when desired, of 15 miles an hour.

Cambridge.—The electric lighting of Cambridge is to be proceeded with at once, and contracts for the tenders recommended by the Corporation's adviser, Dr. Fleming, are to be prepared and submitted to the Council for their approval. Such is the result of the quarterly meeting of the Cambridge Town Council last week. The Electric Lighting Committee reported that various points in Dr. Fleming's report are receiving their careful consideration, but that they were not in a position to make a recommendation upon it. The Rev. Alderman Finch moved an amendment to the effect that the committee be instructed to prepare contracts. A discussion followed, in which the opinion was expressed that the estimates prepared were much overloaded. On the other hand, Councillor Young said that the most rosy view showed only 5 per cent., and Dr. Fleming had made no allowance for cost of land and of collection. They had gone to great expense to employ Dr. Fleming to advise them, and now the Council was asked to make a further estimate. Councillor Vintnor supported the amendment, as it was stated that the lighting was to be for the whole town, and whether they got a profit at first or not, he was sure in the near future they would do so. The amendment was carried, with the effect stated in our first sentence.

International Railway Congress.—The questions to be discussed by the International Railway Congress, to be held this year in St. Petersburg, have been announced. Amongst the large number which appertain to the direct working and control of railways, there appear several which are of importance to electrical engineers. Questions: (16) Fixed signals and the block system; (17) The lighting of signals; (18) Train signals, communication between carriages and locomotive; (37) Special forms of motive power, including electric railways; (40) Light railways as feeders, and the use of tramways or telpher lines as auxiliaries; methods adopted by the main lines to establish these feeders. We should also like to see the discussion of some more scientific method of fog signalling by electricity, as by the method recently commented on in these columns by Messrs. Andrews and Guy. The recent fogs in London must have cost thousands of pounds to the railway companies, and a method by which an indication of the signals could be given on a miniature semaphore on the engine, if practicable, should be brought forward before the congress and throughly discussed. The other questions have already received much attention from electricians and electrical engineers, and it needs no words upon our part to point out the desirability of bringing practical apparatus or designs before this important congress.

College Extension.—A meeting was held on Monday in support of the funds which are being raised for the extension of King's and University Colleges for laboratories and endowment. The Lord Mayor presided, and the Bishop of London moved the resolution that it is essential for the welfare of London that its university teaching should be maintained at the utmost efficiency. Mr. W. H. Preece, F.R.S., spoke in favour of the endowment of science, and regretted the largeness of London acted against the feeling of local interest which induced such men as Whitworth, Mason, Firth, or Owen to leave their wealth to education. It was the bounden duty of England to maintain its own amongst the war of competition by increased facilities of education. During the meeting it was announced that among the donations already given or promised are £6,000 from Lady Siemens for a "William Siemens Laboratory" of electrical engineering; boilers and engines from Messrs. Davey, Paxman, and Co.; £1,000 from the Clothworkers' Company, in addition to £225 a year devoted to exhibitions; about £1,100 from the Carpenters' Company; £1,000 from Lord Grimthorpe; £1,000 from Mr. W. H. Smith; and £250 from Prof. Banister Fletcher for an architectural museum. Another £4,000 is required for the electrical laboratory at King's College, and new electrical and mechanical laboratories are required for University College.

Croydon.—The question of overhead wires came before the Croydon County Council last week, when the town clerk reported that the Board of Trade propose to insert in the provisional order a clause to the effect that overhead wires shall not be erected without the consent of the Board of Trade. No such prohibition was contained in any provisional order granted to a local authority last session, and although it is probable that in all the principal streets, and perhaps throughout the borough, the Council would think it desirable to have underground wires, yet the committee consider the restriction undesirable, and appointed a deputation to wait upon the Board of Trade and remonstrate against its insertion. Councillor King asked why it was proposed to go to the Board of Trade and ask them to leave out the clause prohibiting overhead wires? It would be a serious thing if the town were lighted by electricity from overhead wires and then for the wires to break down, as they did in New York recently, throwing the whole city into confusion, and making the telephone and telegraph services absolutely useless if a fire had broken out. Councillor Goodwin said he viewed the introduction of overhead wires into Croydon with a great deal of apprehension, and hoped the committee would not be so unwise as to try to remove the restriction the Board of Trade had placed upon the matter. He moved an amendment to that for the adoption of the report to the effect that the paragraph be omitted from the report. The amendment was, however, lost by an overwhelming majority.

An Electrical Omnibus.—A sensation was created the other afternoon in some of the streets of the City, says the *Financial Times*, by the appearance of Mr. Radcliffe Ward's patent electrical omnibus. It was brought out for the satisfaction of a few shareholders of the small private company which has taken up the enterprise, and who occupied inside seats, their desire being to test its running with a view to the starting of a regular passenger traffic with such vehicles. Mr. Ward drove the car himself, the going being very easy, and sharp curves, such as that where Throgmorton-street joins Old Broad-street, were turned without any mishap. A few horses were startled, and cabbies and ordinary 'bus drivers seemed to regard the machine as an unwelcome monstrosity, judging from the volleys of derisive chaff with which they continually assailed it. One elderly worthy, in charge of a hansom, who evidently took our representative for the boss of the show, seemed, however, to think a tone of gentle admonition more effective, for, with a solemnity of manner, worthy of the elder Mr. Weller, he impressively asked, "Do you call this a proper sort of vehicle to take through the streets of London?" The rapidity of motion did not allow time for a reply, but our representative's conclusion was that if the electrical 'bus can always be as successfully worked as he saw it managed by Mr. Ward, it will be unobjectionable when the horses have got used to it. Mr. Ward declared the management easy, and said a 'bus of this nature can be run at a cost of 3d. a mile, whereas the working expenses of the General Omnibus Company are at the rate of 4¾d. a mile.

Colliery Lighting.—The installation of the electric light has been recently been fitted up at Messrs. Pease and Partners' Stanley Colliery, where Edison-Swan lamps of various sizes (from 16 c.p. to 200 c.p. each) are used. The machinery is fixed on the surface, and consists of a pair of Tangye high-speed coupled vertical engines, driving a 6,000-watt dynamo, by means of a 5in. leather link belt. Conveniently near the dynamo there is a neatly arranged switchboard with the main cut-outs, voltmeter, etc., and from this are led off three main circuits. Of these—the first supplies current to the screens and travelling belts, where the coal is picked over by hand; the second lights the pitheap and two seams underground; the third lights the offices, workshops, and yard. The screens and belts are lighted by pendant lamps of 16 c.p. each, fitted with strong white enamelled iron reflectors, by means of which all the light is cast down on to the coal. On the pitheap and round the shaft bottom in each seam 50-c.p. lamps are used, and these are enclosed in strong galvanised iron wire guards, which save the lamps from being broken by an accidental blow. In the yard in front of the workshops there is fixed a 200-c.p. lamp, enclosed in a strong weather-proof, enamelled iron fitting, with an outer globe of clear glass; and on the gangway two 100-c.p. lamps, in similar fittings, are now being erected. The stables, joiner's shop, smith's shop, etc., are all lighted by 16-c.p. or 25-c.p. lamps, either protected by wire guards or fitted with enamelled shades, as was found most suitable. This plant has now been running some little time, and, we believe, is giving every satisfaction. The contractors for the whole of the work were Messrs. Barnett, Barnard, and Co., of Newcastle-on-Tyne, who have lately taken over the Newcastle branch business of Messrs. Sydney F. Walker and Co.

Barnsley.—The electric lighting question at Barnsley is still unsettled, and there is the same state of indecision and absence of definite plan that has unfortunately characterised several important schemes of public lighting. At the meeting of the Barnsley Town Council on Tuesday, correspondence between the committee, the Board of Trade, and the Westinghouse Company was submitted. It was to the effect that the Board of Trade withdrew their sanction, and asked the Corporation to supply underground mains instead of overhead, on the score of safety. The town clerk pointed out that this would mean £20,000 extra cost on the town, that consent to borrow £23,000 had already been obtained, that a provisional contract had been entered into for Westinghouse plant, and that if underground mains were insisted on the town would not be lighted. The Board of Trade, in view of these facts, replied they would not absolutely refuse, but "hope the Corporation will bear in mind the desirability of placing the electric lines underground, and will take the necessary steps to do so if the opportunity should arise." The correspondence with the Westinghouse Electric Company simply amounted to the company throwing up their contract, and the committee recommend "that no further negotiations be entered upon with that company, and they defer the issue of advertisements for other tenders for consideration at next meeting." Alderman Blackburn moved the adoption of the minutes, and said they must before going further into the question have information what course the Board of Trade would take in the future, as if the underground wires were insisted upon the Barnsley Electric Lighting Act would remain unexecuted. Mr. Wray said that if overhead wires were approved they should go on. The whole question was yet for the committee to consider and report. The minutes were then adopted.

St. Pancras.—St. Pancras Vestry, which alone of London local authorities has decided to undertake electric lighting, incurring an initial expense of £50,000, is proceeding expeditiously with the execution of the necessary works. The Electricity Committee, reporting to the Vestry meeting on Wednesday, stated that the Stanhope-street station was approaching completion, and the mains first to be laid would be forthwith laid along Tottenham-court-road and Hampstead-road, and along Euston-road from Euston-square to Cleveland-street. The mains would be for both arc lights and incandescent lights. Alderman Gibb, vestry clerk, reported with respect to the Electrical Exhibition to be opened at the Vestry Hall, Camden Town, on Monday, the 16th proximo, that there would be 35 exhibitors, and it was doubtful whether all applicants could be accommodated with space. Mr. Preece, chief electrician of the General Post Office, would in all probability take an active interest in the exhibition, which would be open for a week, a small charge being made for admission, and this, with the payments for space, would, it was believed, cover the necessary expense—no recourse being had to the rates for the purposes of the show. Among the intending exhibitors are: Willans and Robinson, the Electrical Construction Corporation, Gill and Co., Edison-Swan Company, Benham and Froud, Strode and Co., Rashleigh, Phipps, and Dawson, Clark, Muirhead, and Co., Johnson and Phillips, and Woodhouse and Rawson. The Electricity Committee had appointed an exhibition sub-committee to confer and act with the Exhibitors' Committee, and the intended exhibitors had taken up the project in so earnest and energetic a manner that there seemed to be but little doubt that the exhibition would be in every sense a success. A further report of the Electricity Committee stated that the Vestry were allowed to charge per unit for the electric current the sum of 8d. The actual cost, the committee expected, would not exceed 4½d. They thought the price charged should for the present be less than that charged by the companies, but should at the same time secure a profit to the Vestry. Hence they recommended that the charge be 6d. per unit, but that for the present no minimum charge be fixed. The reports were unanimously adopted.

UNDERGROUND MAINS.—IV.

THE CALLENDER SOLID SYSTEM.

(Concluded from page 183.)

The accessible junction-boxes are fitted with an indiarubber gasket round the joint of cover, and are screwed down with a phosphor bronze set-screw.

The buried junction-boxes are used under roadways, and are covered with the ordinary pavement without cover plate, the paving being lifted if it becomes necessary to examine the connections, in which case the bitumen can be easily removed by the use of a heated tool.

Ordinary sizes of cables are: for feeders $^{91}/_{11}$, equalling one square inch sectional area, $^{61}/_{11}$, equalling $\frac{6}{10}$in. sectional area of copper, and both can be laid up to 250 yards length; for heavy feeders $^{91}/_{9}$, equalling $1\frac{1}{2}$in. sectional area, laid in 150-yard lengths. The distributors are usually $^{37}/_{13}$ cable, $\frac{1}{4}$in. sectional area, or $^{19}/_{14}$, $\frac{1}{10}$in. sectional area, laid, according to circumstances, up to 600 or 700 yards. The latter size is usually employed for the house service lines.

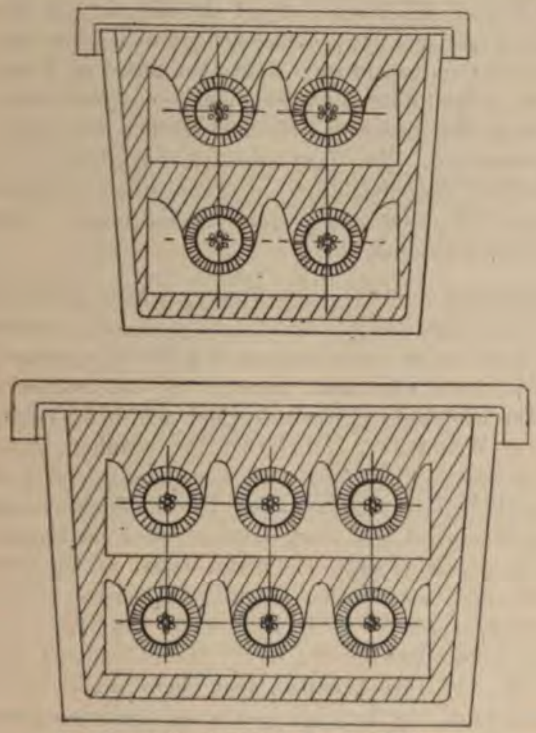

FIG. 7.—Callender High Tension Cables.

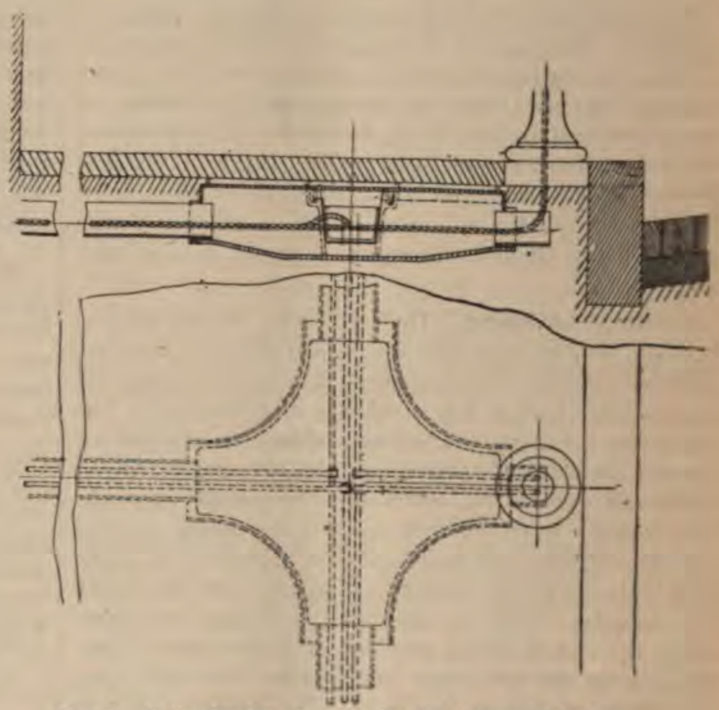

FIG. 8.—Callender Junction Box for Arc Lamps in Series.

The Callender solid system is particularly applicable to high-tension systems for arc lighting in series where the mains have to be led from lamp to lamp under the streets, and the strength of current remains constant, without necessitating increase of cable section even if the number of lamps is increased.

Sections of mains for high tension are shown in Fig. 7, where the sizes of troughs for four and for six highly-insulated $^{7}/_{16}$ cables are given. The process of laying is exactly the same as that previously described, with the exception that the troughs are always covered with a cast-iron cover, or in particular places with steel covers, to afford absolute security against accidental interference by picks of other workmen.

The method of connection of the arc lampposts in series is seen in section and plan in Fig. 8, where a junction-box at a street corner is shown. The cables are laid in the trough with sufficient spare length to go up the lamppost without joint, a junction-box being let in under the pavement and covered with a steel plate lid. These high-tension mains can be easily laid in lengths up to one mile without joint.

The following is a fairly comprehensive list of central stations at which the Callender and Callender-Webber mains have been laid down:

Chelsea..................	The Chelsea Company. Draycott-place station, Clabon-mews station, complete set of feeders and distributors.
South Kensington...	Ditto. Egerton-gardens central station. Ditto.
Whitehall	Metropolitan Company. At Charing Cross.
Strand	Electricity Supply Company (late Gatti). Bull Inn-court station, and along the Strand, Charing Cross district.
Liverpool.........	Liverpool Electric Company. Three stations, comprising the complete district between Lime-street and the Docks.
Birmingham	Birmingham Company. All the central portion of the city.
Bath	Mr. Massingham. Arcs for the town lighting. Incandescent supply for private lighting.
Brighton	Network for Corporation plant.
Le Mans, France ...	Central station network.
St. Austell	Central station for private supply.
Victoria Station......	Edison and Swan Company. Installation for the railway station.
Law Courts............	Crompton. Law Courts building.
Temple..................	Edison-Swan Company. House lighting in the Temple.
Westminster	Westminster Company. Many miles of C.-W. casing laid in conjunction with Crompton mains where culverts were unsuitable.
Northampton	Crompton and Co. Several lengths of main, laid both on C.-W. and solid system, in conjunction with Crompton culverts.

In addition to which are a large number of mains for isolated installations, amongst which are: Buckingham Palace (Her Majesty Queen Victoria), Hatfield House (Lord Salisbury), Normanhurst (Lord Brassey), and many others.

ELECTRIC TRACTION.

I.—THE ELECTROMOTOR.

Although the successful employment of electricity as a mode of energy in the *transmission of power over a distance* has been known for more than 50 years, it only reached a practical and efficient outcome when Siemens and Gramme devised their world-known improvements in dynamo generators, and when the Gramme machine, some time after it was brought out, was shown to be reversible—that is, could be employed almost equally well as a motor yielding mechanical energy, or as a generator yielding electrical energy.

Before, however, enquiring even generally into the uses of electric motors for the transmission of power, it may be advisable to clear the ground in some degree by defining, more or less accurately, the leading phrases or terms to be employed in considering the entire system. The word "dynamo," for instance, had for a long time the meaning of "electric generator" simply, being thereby opposed somewhat to the term "motor"; but as a rule it is nowadays held to include both generator and motor.

To define these terms more narrowly, we may say that an electric generator is an appliance in which mechanical energy is used to obtain electrical energy, whilst an electric motor, being the converse of this, is an appliance supplied with and utilising electrical energy for conversion or transformation into mechanical energy.

Speaking now in more concrete fashion, we have, in the case of a generator, the engine, turbine, windmill, or other prime mover, which drives the generator by means of shafting, belts, or any other such gear. The generator, being thus mechanically actuated, can be made to yield currents of electric energy capable of being carried along suitable intermediaries over any distance, and often utilised to give light, heat, or power.

In the case of a motor, the energy supplied to it is in the shape of electric currents, and from certain reactions which thereby take place in the motor, an actual mechanical motion is required on the spindle, such as is required to drive machinery of any kind.

Although a distinction has herein been drawn between "motor" and "generator," it need not be thought that any essential difference of principle exists; the two appliances may be of identically the same design. The difference lies in the manner according to which they are used. Take any dynamo, and drive it by means of a belt from an engine, electrical energy may be obtained as a result from the machine, which accordingly is said to be a generator. Take the same dynamo, and allow to pass through it a current of electrical energy from some outside source, under certain restrictions the dynamo will run as a motor, yielding mechanical energy, and if the electric current supplied to the motor from outside be sufficiently powerful, the motor might even—if still connected to it by the belt—drive the engine or other prime mover, thus completely reversing the previous order of things.

In other words, dynamos are reversible in action: drive them mechanically, and they yield electric energy; pass a current through them, and they rotate so as to give mechanical power and motion.

So far, generator and motor have been regarded apart from one another as individual and separate appliances, but it is of course evident that they can and must be used in combination. That is, in order to use a motor, we must also have somewhere a generator of large capacity for obtaining the necessary supply of electric energy.

The great principle of conservation of energy is seldom better seen than in this instance, and users of electric motors will do well to bear that principle constantly in mind.

We start with a given amount of energy in our prime mover, and lose some of it, to begin with, in engine belts or shafting, besides which, our electric generator is not altogether perfect. Probably, out of the electric generator we may obtain in the shape of electrical energy about 80 to 90 per cent. of the mechanical energy given off at the engine flywheel. Before using this electrical energy for purposes of light, heat, or power, it needs to be conveyed from the generator to the place where it is required, and there ensues a slight loss in this transference of electrical energy, although the means of conveyance (in the shape of metallic wires) are the best and most adaptable that can be devised.

Then there is a fourth loss in the electric motor, wherein takes place the transformation of electrical into mechanical energy, and a final amount—though small in quantity—is lost in the means adopted for employing the mechanical energy thus obtained, such as belts, and other gear.

There are accordingly five directions in which loss or waste (as regards the original energy) may take place, and these can be shown in the following manner:

1. From flywheel to generator, or loss by transmission.
2. In the generator itself, or loss by transformation.
3. From the generator to motor, or loss by transmission.
4. In the motor itself, or loss by transformation.
5. From the motor to machines requiring to be driven, or loss by transmission.

Now attention has been directed to these points—which may perhaps cause the electric transmission of power to appear on the surface anything but advantageous—for the special reason that the losses of energy thus incurred at each step *are extremely small and unimportant* when comparison is made with other methods of employing power at a distance.

This statement is made more especially with regard to long-distance transmission of power—such as would be involved nearly always in the various systems of electric traction, the subject with which we are now most concerned, rather than short-distance transmission; but there are many cases where it is profitable to use electric motors even a few feet away from the prime mover and electric generator. These instances, indeed, will be found on examination to constitute the "rule," and by no means the "exception."

"The difficulties of all systems of transmission increase with the distance, but for electricity not so much so as for mechanical means, and consequently the advantages of electric transmission become more apparent at long distances."

It is more particularly with such long-distance transmission that electric traction has to deal.

Other systems of transmitting power include the use of such methods as shafting, cotton ropes, and other forms of belting, steam, compressed air, water at high pressure, and wire ropes; and as regards all of these it may fairly be claimed that electricity is enabled to show convincing proofs of its great superiority, taking all points into consideration.

"How easily, and how quickly, and with little occasion for repairs, can two flexible cables be laid, in almost any position, for mines, iron works, docks, factories, as compared with shafting, ropes, steam-pipes, compressed air."

In deciding upon any one system of transmission of power the ultimate appeal must inevitably be made to *cost*—that is, first, the capital outlay, and second, working expenses.

On both these points electricity excels any of the systems named, wire rope transmission alone being in the least a competitor in lowness of first cost for distances up to, say, three miles. As for efficiency and economy in cost of operation, electric motors have at the outset a considerable advantage in consuming power in strict proportion to the work done, so that no energy is wasted.

The motor absorbs from the generator just as much energy as it requires to do the work that is given to it, plus a small quantity to overcome friction, etc., and the generator in turn calls on the engine by means of the belt for a corresponding amount of energy. The absorbed power is therefore exactly proportional to the work that is being done. "Electric motors help themselves, as it were, to only such an amount of energy as will enable them to deal with the work imposed on them."

Returning now for brief reference to the losses enumerated in the complete transmission from prime mover to machine moved, it should be pointed out that the first one—that which takes place between the flywheel of prime mover and pulley of generator—will be found in practice common to all systems of transmission over a distance. The next one, loss in the generator itself, is very small; it is a poor dynamo which will not give an efficiency of 90 per cent. of the energy put into it.

From the generator to the motor—along the conductors, or intermediary wires, through which pass the currents of electric energy—there is another loss, but one that with careful designs and good workmanship should prove less in comparison than with such methods as compressed air, steam, gas, or water.

Copper wires are always more easily managed and erected than iron pipes, besides which the prime cost is usually less.

In the electric motor, again, there should be as great an efficiency as in the generator, and, indeed, it would be somewhat difficult to name many energy-transforming machines or appliances which return so much of the energy put into them. The generator and motor in combination can, as a rule, be depended on for an efficiency of 80 per cent.

The loss between motor and machines or appliances to be driven is purely the mechanical one of belting or gear friction, and can be got rid of at once by the simple expedient of coupling the motor spindle direct to that of the machine to be driven.

As a rule, it is not desirable to reduce the speed of electric motors too greatly; in many cases the faster they run the more efficient they become; and if, therefore, high-speed machines are to be driven, the motors are coupled direct to them so as to increase their electrical efficiency, and at the same time avoid the loss of transferring their mechanical energy through the medium of belts or other gear.

Although, therefore, it might be thought that the transmission of power by electricity cannot possibly prove so economical as, for instance, a system of wire rope transmission, because the former has no less than five conceivable sources of loss between the prime mover and the machine to be moved, whereas the loss of energy in the case of a wire rope is confined simply to that involved by the friction, etc., of a long and constantly travelling endless rope, with the necessary pulleys and wheels for it to run upon; yet when it is remembered that the loss in the latter case (except for quite short distances) may reach as great an amount as 60 per cent. or more, whereas the total loss on all the five points mentioned in connection with electric transmission should not exceed 35 per cent. at the utmost, it will be seen at once that owing to high efficiencies at each conversion, the more roundabout method is, after all, more economical—the "longest way round is the shortest road home."

(To be continued.)

CANTOR LECTURES.

Mr. Kapp requests us to publish the following copy of a letter addressed to the General Electric Power and Traction Company, having reference to these lectures.

[COPY.]

Messrs. The Electric Traction and Power Company, Limited,
Maldon-crescent, Prince of Wales-road, Kentish Town.

Dear Sirs,—I was surprised to hear last night from Mr. Snell that he considers the figures I gave in my Cantor lecture with reference to the Barking-road tramway incorrect. When towards the end of last year I applied to Mr. Frazer for information about the working of battery cars, I was under the impression that this gentleman was the member of your company who had the entire control of your traction work, and I therefore took the figures which he gave me as authentic and correct. If, however, as Mr. Snell asserted last night, the figures are not correct, it appears desirable that the necessary corrections should be made in the tables I gave at the Society of Arts lecture; and I shall do this if you will kindly supply me with the exact figures.—Yours faithfully,

Erba, Wimbledon, GISBERT KAPP.
February 20, 1891.

The secretary of the company also requests us to publish the following letters.

[COPY.]

Gisbert Kapp, Esq., Feb. 20th, 1891.

Re Cantor Lectures on Monday, 16th inst.

Dear Sir,—I am requested by the managing director to draw your attention to the enclosed printed matter with reference to data relating to the Barking-road electric installation, which is the property of the General Electric Power and Traction Company, Limited. The figures thus given are entirely misleading, and the publication of them is calculated to seriously injure our interests as well as those of the North Metropolitan Tramways Company, and we must request you accordingly to withdraw the Tables 4 and 5, and the statements made by you based thereon at the Cantor lecture, in such a public manner as will be likely to reach all persons before whom the original tables and statements have come.

If the statements have been based upon information obtained from Mr. Frazer, we may call attention to the fact that he left the company's employ in July last, and has since had no opportunity of acquiring any knowledge as to the improvements that have taken place since then, which renders the data published by you still further misleading.

In the event of your failing to comply with our request, we shall, in the interest of our shareholders, be compelled to consult our solicitors on the subject.—Yours faithfully,

(Signed) W. G. M. MACKENZIE, secretary.

[COPY.]

31, Parliament-street, S.W.,
February 21st, 1891.

The General Electric Power and Traction Company,
Limited, 35, New Broad-street, E.C.

Dear Sirs,—In reply to your letter of yesterday, the statements to which you object were based on figures obtained from Mr. Frazer, and were given at the Society of Arts distinctly on his authority, and not on mine. After your explanation, which puts a totally new complexion upon the matter, I am, of course, myself most desirous to withdraw from my lecture any statement or table the accuracy of which is questioned, and I shall on Monday withdraw the two Tables 4 and 5, and statements connected with them. At the same time allow me to point out that in your interest as well as in mine withdrawal alone would not be so effective as withdrawal combined with the substitution of the correct figures, and I shall feel obliged if, on Monday, you would send me a telegram authorising me to state that when the lectures appear in print, the obsolete figures of Mr. Frazer will be replaced by figures corrected up to date and supplied by you.—Yours faithfully,

(Signed) GISBERT KAPP.

NEW THOMSON-HOUSTON SLOW-SPEED RAILWAY MOTOR.

We illustrate on this page a new motor which the Thomson-Houston Electric Company has been at work upon for some time, and with two of which a car on the West End road in Boston has recently been equipped. It has been named, from its construction, the "single reduction gear" motor, but is ordinarily called the "S.R.G." As will be seen in Fig. 1, the motor is very nearly iron clad, having two pole-pieces of ample surface, and carrying two field coils, which partially surround the armature core. The magnetic circuit is completed on the front end of the motor through the face plate and at the back through the frame on which are cast the axle-boxes and arms which serve as a support for the armature shaft bearings. The armature is of the Gramme ring type, and the bobbins are wound close together around the entire rim, Fig. 2. One great advantage of this construction is the fact that any coil can be easily rewound without disturbing its fellows, while with the drum armature in the type of motor formerly used by the company the winding all had to be renewed down to the injured coil.

The brushes are placed exactly opposite and in a horizontal fixed position. There seems to be no sparking under the ordinary running conditions, and the brushes are easy of access.

The field spools are protected on all sides by the fields and frame. The gears are entirely enclosed in a dust and oil-tight case, which is provided with a hand-hole closed by a spring cover, permitting ready examination of gears and the introduction of lubricants.

A sheet-iron pan extending above the centre of the armature shaft entirely encloses the bottom and sides of the motor and protects the armature and commutator from dust, snow, and water. The advantage of this casing was strikingly demonstrated during the recent snow storms, the "S.R.G." coming through unharmed, while some of the fields on the old style of motor came to grief from the effects of excessive moisture. This pan has a sliding bottom, and is attached to the motor in such a manner as to permit of being readily removed for access to the various parts.

The motor when mounted on a truck with 30in. wheels is designed to clear the tops of the rails 4in. The spur gear on the armature shaft is of steel, 4½in. face, and has

14 teeth. The split gear on the car axle is of cast iron, with the same width of face, and has 67 teeth. The speed of the armature shaft relative to that of the car axle is nearly as 4·8 to 1; when the car is running 10 miles per hour the armature makes 538 revolutions per minute, or the speed of the armature is 53·8 turns per minute when the car speed is one mile per hour. The gears are surrounded by an iron box so that they may be run in oil.

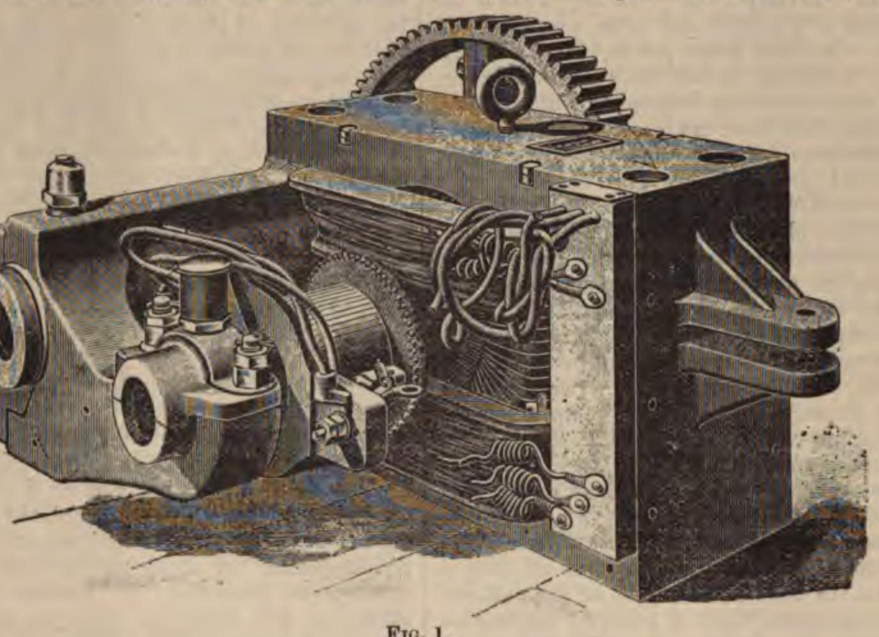

Fig. 1.

The facility with which the armature can be removed simply by lifting the upper field, the ease with which an armature bobbin can be rewound, less liability to damage from centrifugal action, such as bursting of binding wires, displacement of coils, breaking of commutator connections, all ensure a minimum amount of expenditure for repairs.

The accompanying illustrations show very plainly the general appearance and detailed construction of the motor.

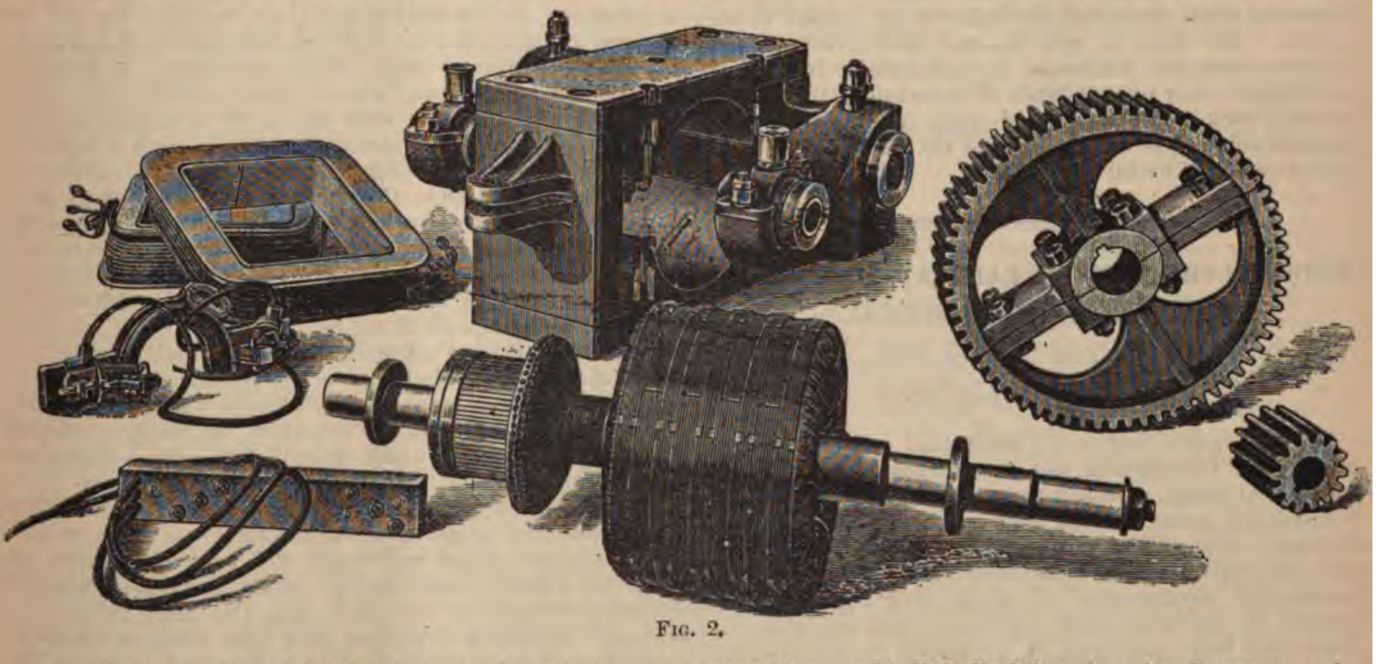

Fig. 2.

The advantages claimed by the designers have been summarised as follows:

1. Noiseless single reduction gears, protected from dust and run in oil, and noiseless commutator. 2. Electrical and mechanical simplicity attained by use of two-pole type of motor. 3. Slow speed and powerful torque obtained by proper proportions. 4. Protection for fields and armature from dust and water. 5. Accessibility to all parts. 6. A ring armature not likely to become damaged, and, if accidentally injured, permitting easy repairs. 7. Moderate weight. 8. Reasonable cost. 9. Commercial efficiency. 10. Small maintenance expense.

LITERATURE.

"The Law and Practice Relating to Letters Patent for Inventions." By Robert Frost, B.Sc., F.C.S., Barrister-at-Law. Stevens and Haynes, Bell-yard, E.C.

There are various ways of writing law books now in vogue. A man may simply go through all the decided cases, and making a short abstract of each set this down as it stands, arranging the cases subsequently according to subject-matter: as, for instance, is done by Mr. Clement Higgins in his useful Digest of Patent Cases, or he may go a step further and weave these cases into a connected argument, as in Benjamin's Sale of Goods, or Lindley's Partnership; or again he may write a legal treatise on the whole subject, founded upon a careful study of all the cases, and citing them as his authority for each successive proposition: as Sir F. Pollock has done for Contracts, and Torts, and Mr. Joshua Williams for Real and Personal Property.

A fourth course is open when the law on the subject is contained in statute; which is to take the principal statute as a backbone and attach to it a continuous commentary, citing the cases in the notes on the various sections, as Mr. Lawson has done excellently for patents. The law on patents, however, is not to be found in statutes, except so far as procedure and the legal effect of the necessary steps and preliminaries are concerned. Mr. R. Frost, therefore, has done well, in our judgment, to adopt the third of the processes we have indicated when writing his new book on "Patent Law and Practice." For it is not to statutes, but to the cases "tried and determined by and according to the common laws of this realm," under the second section of the old Statute of Monopolies of 1623, that we must look for the law that is material for our guidance on the questions most frequently raised in the courts in patent cases. Such questions, for instance, as the meaning of "true and first inventor," or of "novelty" and "utility," what is the proper subject-matter of a patent, and what constitutes an infringement of it. On these moot points, Mr. Frost has done well to cite verbatim, rather than to summarise, passages from the most important judgments, both old and recent. And he appears to have made a judicious selection of them, adding references to other cases when necessary. Practice, however, and procedure are part of Mr. Frost's subject, and he has dealt with them not only in his text, but also by the addition of an exceedingly bulky appendix. The latter contains, besides the statutes, rules, and foreign conventions relating to patents, almost every form and precedent that the author could lay his hands upon, whether issued by authority or required in drafting, many of which are and some may be found useful for reference. This large appendix, which forms nearly a third of the whole book, would appear to be intended mainly for the use of any patent agents who are out of reach of the Patent Office; the multifarious forms are certainly of little use to the legal profession. Both in these forms and in the text of his work the author betrays many marks of a "'prentice hand." Small slips in form as well as a want of familiarity with general law, of which patent law, is after all, only a branch, indicate that the book is the result of the author's industry and research, rather than of his own experience and matured opinion. For instance, besides avoiding the numerous trifling inaccuracies which Mr. Frost has inserted, a lawyer would hardly think it necessary to set out a number of cases to show that where there is no fear of a defendant continuing to infringe a patent, the Court will not grant an injunction against him.

It used to be a common saying that there were only three ways of getting on at the Bar—marrying a good solicitor's daughter, writing a good book, and a miracle. The writer of this book is to be commended for trying the second of these ways, and he deserves to succeed in his object. His book is well planned and arranged, and contains abundant references to authorities. It does not add much to our present stock of knowledge, but it is yet a useful book of reference; and when improved for subsequent editions, as will no doubt be the case, may develop into a good and useful law book.

NOTES ON THE ELECTRIC RAILWAY: HISTORICAL, STATISTICAL, AND TECHNICAL.*

BY FRANKLIN LEONARD POPE.

(Continued from page 187.)

The principle of converting mechanical energy into electricity and reconverting this by a reversed dynamo into mechanical power, naturally suggested the practicability of transmitting power through electric wires to any required distance. One of the earliest results of this conception was the revival of the electrically operated railway, the commercial development of which had necessarily remained in abeyance until machinery was available for furnishing large quantities of electricity at a moderate cost.

One fact of controlling importance in this connection is that electricity is capable of being supplied to a moving motor through a frictional or rolling contact, a method of communicating mechanical power impossible of realisation by any other known means. Hence the possibility of supplying a power by machinery situated at any required distance from the moving train by extending the conductor to and along the railway.

The credit of priority in the invention of the electric railway in its modern form—that is to say, the moving electromotor on the car connected by electric conductors with a stationary dynamo—I believe to be justly due to Stephen D. Field, now of Stockbridge, Mass., who was living in San Francisco in 1877. This was about the time of the introduction of the cable system of street railways, which was resorted to in San Francisco, for the reason that some of the grades were so excessive that the use of horse power was absolutely out of the question. Observing the operation of the cable road, it at once occurred to Field that electric power might be applied to the same purpose with as great or even greater advantage. At that time no dynamo-electric machines suitable for this purpose were to be had in the United States, and he accordingly ordered one from Europe for experimental purposes. It took a long time to make it, but at last it was completed and shipped to San Francisco by a sailing vessel. The vessel was wrecked on the voyage, and the machine went to the bottom of the sea. Not yet discouraged, he ordered another one, which eventually reached him in good order, and enabled him to commence his long-delayed experiments. He tried first an electric elevator, in which he was successful. In 1879, having exhausted his resources, he came to New York, bringing with him his plans, with which he hoped to enlist capital to continue his work. He laid these plans before me, and being impressed with the entire practicability of his scheme, I gave him every encouragement in my power. The plan which he had devised contemplated the enclosing of the conducting wire in a conduit beneath the street. He was not successful in obtaining sufficient means to properly develop his invention; he became involved in tedious, harassing, and expensive litigation with wealthy corporations, and his health failed him at a critical time, so that for years he was incapacitated from active work; but the single railway which is in operation in this country to-day, and embodies his matured conceptions, is regarded by competent judges as in many respects superior to any yet brought before the public. Field's electric locomotive was first exhibited at the exhibition of railway appliances in Chicago in 1883, during the continuance of which 27,000 passengers were transported by it.

In the summer of 1882, Dr. Joseph R. Finney exhibited in Allegheny, Pa., an electric street car, for which the current was supplied by a copper wire, about the thickness of a lead pencil, 15ft. or 20ft. above the street. A small trolley fitted with grooved wheels, running on this wire as on a track, and connected with the car by a flexible conducting cord, served to convey the electric current from the suspended conductor to the motor. Some of the earliest of the successful lines in this country were arranged upon this plan. At a later date this was superseded by the type of contact wheel now in general use, which runs underneath the wire and is mounted upon the end of a long yielding rod bearing a certain resemblance to a fish-pole supported upon the roof of the car.

I have said that the original invention of Field contemplated the supply of electricity to the travelling car from conductors enclosed in a conduit beneath the pavement. He, as well as many other inventors, appreciating the force of that prejudice which undoubtedly exists—among newspaper editors—against any avoidable multiplication of overhead electric wires in the streets, realised that the great prize to be sought for above all others was the invention of a system of electrical supply which should dispense altogether with the overhead line. Hosts of inventors have diligently wrought for 10 years upon this most difficult problem. Hundreds of patents have been taken out, and more than a million dollars have been disbursed in paying for tuition in the costly school of experience. More than once, and in more than one direction, success has at times seemed almost certain, yet truth compels me to say that from the hard practical standpoint of dollars and cents, by which every invention must first or last be tried, the net outcome of all this vast expenditure of labour, time, and money has up to the present moment been almost insignificant. The reward which awaits the fortunate person who succeeds in completely solving this problem may well be regarded as a potentiality of wealth beyond the dreams of avarice.

---

* Paper read before the New York Electric Club, Jan. 22.

The problem of the underground conduit does not at first sight appear to be a very difficult one. It renders necessary, in the first place, a construction which will effectually resist the action of forces tending to disturb the condition of the wires, and with the heavy traffic on the streets this involves a very strong structure. It is absolutely necessary that the conductors shall remain insulated from each other and from the ground, under all conditions of weather. The exigencies of heavy rains and snows necessitate a construction which shall permit of a thorough insulation of the conductors and a drainage of the entire system. There are other minor points which require to be taken into consideration. Without going into details, it is sufficient to say that the conduit system has been tried on an extensive scale in Denver, Cleveland, and Boston, and to a lesser extent in several other places, but in every case the continual interference and interruptions consequent upon its use have exhausted the patience of the travelling public and compelled its abandonment. I do not wish for one moment to convey the impression that the problem is an insoluble one. My attitude is rather that which was taken by Prof. Tyndall some 10 years ago upon the question of the practicability of domestic electric lighting by incandescence. He had no doubt that the problem would be solved, but it was a great satisfaction to him to know that it would have to be done by somebody other than himself. I may, perhaps, say that I think great progress has been made in this direction within the past year, and I cannot but feel that the disappearance of the overhead system from the streets of all our larger cities and towns is only a question of time, although the objections which have been most strenuously made to its introduction are for the most part rather of a sentimental than of a practical character.

The storage battery system, both from the standpoint of the public and of the street car manager, is an ideal solution of the problem of electrical transportation. It has many features which especially commend it for city work. Each car is an independent unit, and hence no accident can materially cripple a well-organised system. The idea of being able to store a large quantity of electricity in a box under the seats of a car, to carry it around, and to draw from it a large amount of power, as required, is a most attractive one. Storage battery cars can be introduced in the existing systems, one car at a time. In cases of emergency they can be run over almost any route where a horse car can be run, not being restricted to the route of an electric conductor, and under ordinary circumstances the car can be run just as rapidly and controlled just as effectively as it can be with the trolley system.

All these advantages were recognised at an early day, and hardly had the storage battery been invented before it was applied to street car propulsion. The first storage car was operated in Paris, in 1882. The system was put in practical service on one of the lines in Brussels, Belgium, and continued for two years. It was also introduced in 1886, on the Madison-avenue line in New York City, and has been in operation there ever since. The results of the 10 cars now running on the Madison-avenue line appear to have demonstrated that the system may, with careful management, be made thoroughly reliable. Each car will carry a full load on a straight and level track 15 miles per hour, and will ascend grades not exceeding 5 per cent. and not more than 500ft. long at five miles per hour. A run of 40 miles can be made on a level track, which is considered a half day's work, with one charge of battery. The time required to replace the exhausted batteries with fresh ones is not more than two minutes.

There are, however, two serious objections to this system which have thus far been sufficient to prevent its adoption in other than exceptional cases. One of these is the great weight of the batteries, and the other is the lack of reserve power in the emergencies which sometimes occur. In other words, two considerations enter into the question, one of economy and the other of efficiency. To take up the question of comparative efficiency first, a very little consideration of the matter will show that the progress of the art, so far as yet developed, practically limits the use of storage battery cars to lines having very light grades—not more than 5 per cent. at the outside. Very many of our eastern cities—for instance, Springfield, Providence, Worcester, Albany, Troy, and many others which I might mention—have very severe grades, from 7 to 10 per cent., and some of them half a mile long. To start a heavily-loaded car in bad weather on such a grade as this means an expenditure for a few seconds of from 50 h.p. to 80 h.p. Experience has shown that this is far too heavy a tax upon the powers of a storage battery. Even on comparatively level lines, in our northern climates, the occurrence of a heavy storm of snow or sleet necessitates the expenditure of an abnormal amount of power, and it is on just such occasions as these when everybody wants to ride, so that the cars are loaded to their utmost capacity, and great dissatisfaction prevails if there is any delay or any lack of sufficient accommodation. It is at such times as this that the advantages of a distribution from a central station are most apparent. The whole number of cars, or extra ones, if necessary, can be run, and any amount of power required to force them through obstructions and to keep them running on schedule time can be supplied from the power station. It is merely a question of burning more coal.

Considering the economical aspect of the question, first, as to the original cost, it may be said roughly, the difference between the storage and overhead line system is not very great. The whole outfit, exclusive of roadbed, track, and building, for either system, will aggregate perhaps 10,000dols. per car. Now, as to the cost of maintenance and operation:

A 16ft. car with two motors, such as are most commonly used, will weigh 8,000lb., of which 4,000 is electric apparatus.

A storage battery car of the same size and capacity weighs 14,000lb., of which 3,800 is battery.

A full load may be estimated at 30 passengers, weighing about 4,000lb.

It will be seen that the storage battery car weighs nearly as much as two ordinary electric cars. It seems at present impracticable to operate a car with less than 3,800lb. weight of battery, and unless great improvements are made there is little reason to hope that this weight can be materially reduced.

(To be continued.)

BRISTOL.

The Town Council is in earnest now, as far as can be gathered from the proceedings at their regular meetings, on the subject of lighting the city by arc lamps, and of supplying private consumers in either arc or incandescent form. From a tentative scheme which had for its projected area only the four principal streets converging at the Council House, the proposal has grown to such dimensions as will practically include the entire route from the railway depot into Clifton, and will involve the employment of a couple of hundred or so of arcs in the main thoroughfares alone. It is satisfactory that the Council contemplates furnishing light and power at economical rates, and that it will endeavour to retain the control in its own hands, and to execute the works entirely with its own staff, augmented merely by such professional assistance as Mr. Preece, who is advising that body, may recommend. The example of the city of Bath has not been lost upon Bristol, and now that this incentive to action is being felt the hope is freely expressed that from the vast amount of detail the committee have gathered in the course of their visits to other provincial towns and to the metropolis, the Bristol installation will rank second to none for excellence. Many suggestions have been made with regard to the utilisation of the uncommon tide in the River Avon as a motive power, and it is only natural that with a rise and fall so great as 35ft. attention should have been drawn to this source of supply. The point to be attained, of course, is concentration upon some advantageous principle. The force is there, undoubtedly, if it can be brought to a head. Higher up the river, at no great distance, there are also some falls which might be used. In the Far East they grind corn by anchoring a boat in midstream, to which are fitted paddles after the manner of a steamer, the wheels revolving in the current and actuating a set of stamps. Something might be done with waterwheels and dynamos in this way, especially by persons having premises adjoining the river.

THE
ELECTRICAL ENGINEER.

Published every Friday.
Price Threepence ; Post Free, Threepence Halfpenny.
Editorial and Publishing Offices :
139-140, SALISBURY COURT, FLEET STREET,
LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

'The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms :—*

	3 months	6 months	12 months.
United Kingdom............	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d	17s. 4d.
Other Places..................	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VI. inclusive, new series, of "The Electrical Engineer" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

We may occasionally follow the lead of our American Contemporaries, especially when they point out a serviceable way. They are not backward in asking their friends to do all they can for the welfare of the paper. We ask our friends to remember us. No Paper that we know ever refuses Subscribers or Advertisers. Nor o we; in fact, we invite them, believing that they will get full value for their money.

Specimen copies of the paper will be sent on request.

HECKLING AT BELL'S ASBESTOS MEETING.

There is an institution long almost sacred to Scotland, and there only used to torture candidates for parliamentary honours, an institution known as heckling. Just, however, as a little leaven leaveneth the whole lump, so heckling seems to be permeating over the whole of these islands, and is especially noticeable at "companies' meetings" in the metropolis. Heckling may be defined as questioning, yet it is not legitimate questioning. It is generally the questioning of an avowed opponent, with the intention of tripping up the one questioned. Ofttimes the biter gets bitten, and then his mood is not to be envied. The meeting of Bell's Asbestos Company the other day was enlivened with a bit of heckling. A shareholder, with one share, and, so far as we could gather, that share given him so recently that his name was not to be found on the register of shareholders, had prepared, or had had prepared for him, a list of a dozen questions which it was evidently thought would lead to unsatisfactory answers. These questions were printed, and distributed at the meeting, were put through after some sharp remarks, and answered very effectively by the chairman, who, in this case, was able to show the questioner or his backers had somehow or other got hold of a mare's nest. However, even in this case the chairman had to refuse point blank to answer one question, as it referred to the internal management of the company. We know absolutely nothing of the questioner at this meeting, and we have no more reason to take up the question as relating especially to Bell's Asbestos Company—we refer to it upon general grounds. At almost every company's meeting such a man is found asking questions. It generally turns out that he has absolutely nothing at stake in the company—is looked upon as a puppet, controlled by strings held by other parties who wish to be unseen, and therefore use a tool. Nevertheless, the prying into the internal management of a company is a nuisance at a public meeting. Competitors successful or unsuccessful are always on the look-out to see how it is done, and a word only is often necessary to enable competition to become keener and more successful. Thus, it may well be that a person interested largely in a rival concern will interest himself to a small degree in the concern whose business he wishes to divert into other channels. It may be safely said, however, that such action is exceedingly uncommon. There is another class whose actions are by no means commendable, which may be entitled company wreckers. For Stock Exchange purposes—that is, for bulling and bearing shares—they circulate all manner of rumours; they ask or get asked questions that have a very ugly look, and which may have a very elastic answer—that is, an answer that may be made to seem different to what it is intended to mean. These men are generally hand-and-glove with a financial paper, and if they can only manage to instil a doubt in the minds of shareholders and the public their end is gained. They can, for a time, play battledore and shuttlecock with prices, and no matter up or down they make money. For some time past there has been a "dead set" at Bell's. The chairman, however, took the bull by the horns, and spoke in pretty straight language on the subject of "tipping" or "commission," which some immaculate, or would - be - thought - immaculate gentlemen have made much of. The system of "tipping" is universal. There is not a reader of this paper who, if he could get a fifty thousand pound order, would hesitate for a moment in giving "com." to the man who influenced that order. Is it fair, then, when a system, good or bad, it is no matter, is general, that directors should be asked by parties that have nothing at stake how they get their business and what "com." they pay for it, and to whom that "com." is paid? We imagine that any *bonâ fide* shareholder can find out how the business is carried on by going to the office and privately investigating. It may even then be politic for directors to withhold certain information, but much more relating to the internal economy of a company can be said privately than can be made public property. The subject of "heckling" is not difficult; questions that really relate to the welfare of a company, and to information it is desirable the shareholders should have, ought always to be answered, but questions that are directed against the welfare of the company, and put for evil rather than good purposes, ought to be met with a blank refusal to answer. Few chairmen are strong enough, many have not the requisite knowledge to adopt this course; but we hope to see a more universal assertion of this principle.

CITY AND SOUTH LONDON RAILWAY COMPANY.

The shareholders of this company, at an adjourned meeting held on Tuesday last, supported the directors in the promotion of a Bill for an extension of their line, or rather for a new line from King William-street to Islington. From the investor's point of view this is clearly a step in the wrong direction. The cost of the City and South London line has been enormous, and it has yet to be proved that sufficient traffic can be obtained to enable a dividend to be paid. Before embarking upon a new and a costly undertaking, it ought to be demonstrated without a shadow of doubt that a return may be earned. Let us look a little more closely into the matter. The capital of the City and South London authorised is £800,000 share capital, and £225,000 of debenture capital, of which practically the whole share capital has been issued, and on debenture account £155,700 has been obtained. There is, then, a sum of £756,000 upon which to pay dividends. A five per cent. dividend takes £37,800, and to earn this, after working expenses have been paid, at twopence per passenger, means carrying 4,536,000 passengers, or about 12,000 per diem. We cannot tell what the working expenses are, but the traffic to pay these expenses is in addition to the above—thus it will be seen the company has a heavy task before it. There may be other means of obtaining income, such as selling surplus land or letting land or buildings, but of this we know nothing. Sufficient, however, can be seen from an examination of these figures to show the problematical nature of a great success, and this should act as a motive for caution in countenancing further extension and the further spending of capital till a moderate success is assured. We may admit that there is sufficient evidence from the traffic returns to cause the belief that the line will be worked at a profit, but that is quite a different thing to knowing that the line is worked at a profit sufficient to pay a modest dividend upon the enormous capital necessary for its construction. At any rate we have uttered our protest against this proposed line, and if speculators are so unwise as to run counter to advice offered to them, not only by ourselves but by other technical journals that have no reason for throwing cold water upon any electrical work, it cannot be said that they have not been forewarned. There is nothing as yet to indicate urgency in this work, although the bogey of "someone else will do it if we don't" may be used to influence shareholders. A very little examination of the subject shows why the proposed line is not to be an extension of the existing line, but a closer examination shows also that the lines will be mutually advantageous whether in the hands of the existing company or in any other. At present you pay twopence and can go the whole distance. If the line were extended, carrying passengers from Camberwell to Islington for twopence would not pay. Thus the break at King William-street means getting double payment from passengers that desire to go over the longer distance without interfering with existing arrangements. First earn a five per cent. dividend, and then proceed.

NAMES.

Almost the last man we should have expected to "gush" after a new name is Mr. Swinburne, and yet he seems to have accepted the "henry" as if it were generally accepted and in universal use. It has been suggested by Kennelly, and is favoured in America, but as yet it cannot be said to have been approved, at least not by any authoritative body on this side the Atlantic. Whatever may be our views of the Institution in other matters, we have a very strong opinion that the Council of the Institution should immediately, upon the suggestion of a new name from a prominent quarter, consider the word, and accept or reject it. We frequently hear of "differences of opinion" in the Council of the Institution, but if that body cannot act as a guide to the profession the sooner it sinks into oblivion the better. The Institution is not a mere body for the getting of papers and making a discussion thereon. It should move the whole body of electrical engineers, not be moved by a small and active section of that body. We might also suggest that some of the papers are rather too discursive—are, in fact, too evidently in need of revision or supervision to be an honour to the Institution or a credit to the reader. Are they always properly submitted to a competent hand before acceptance?

During the past ten years a number of "words" have been coined. That fact shows some terms are wanted, and an authoritative adoption would simplify nomenclature. Years ago we pointed out that a smaller institution, "The Institution of Actuaries," adopted a certain notation and nomenclature, and made it universal in the profession, because they insisted upon its use in their journal. The Institution of Electrical Engineers has more power in the electrical world than the Institution of Actuaries had at that time in the actuarial world, and yet men may use what notation and what nomenclature seems to them good without a hint to the contrary. Certainly some years ago there was a committee formed to consider the question of notation and nomenclature, in which a certain professor took a leading part, drew up certain forms, and then—well, probably, he turned his attention to study electric lighting, and when he has finished that study, in the dim and distant future we may expect to hear something more of the matter. The modern views of electricity seem to want another fundamental "term." Is electricity a phenomenon of the ether? Is the energy of electricity due to the motion of the ether? Is Mr. Preece and his school right in saying what Maxwell called electricity is not the same as what Mr. Preece calls electricity, that, so to speak, there is "electricity" and a "carrier of electricity," and we want a suitable term for the "carrier." Perhaps Mr. Sprague, who seems to doubt modern advances, may have something to say on this subject. At any rate we are certain that the Institution must bestir itself to be an authority on something. Let but some French electrician suggest the idea, and we shall get a congress at Paris—to settle the question. Electricians like Paris congresses.

CORRESPONDENCE.

REFORM IN CONSULTING ENGINEERING.

To the Editor of the Electrical Engineer.

Sir,—I have perused with considerable astonishment the long article in your last issue dealing chiefly with my action in advising the Electric Light Committee of the Dublin Corporation on the acceptance of one or more of the tenders submitted to them.

I regret that the position I now hold in relation to the Corporation prohibits me entering into a detailed refutation of the erroneous statements made therein.

The article in question is a collection of misleading and false deductions, with hardly a spice of truth in it from start to finish. It surprises me, as it doubtless will many other of your readers, that a journal wishing to represent and to advise a profession should publish a substantially incorrect account of proceedings of a committee sitting with closed doors, and of which proceedings therefore your journal could have no authentic knowledge.

I utterly and entirely repudiate the serious insinuations of the article as affecting myself, but as I am leaving town upon urgent business, I must, for the present, be content with requesting you to publish this letter in your next issue.

It is my intention, however, to adopt further measures to clear myself of the imputations made and of which you will hear further.—Yours, etc., E. Manville.

68, Victoria-street, S.W., Feb. 25.

[We would ask Mr. Manville to carefully read our article again. He will then, perhaps, notice points which in his having to attend to urgent business may have escaped him. But in the first place we must say that Mr. Manville is very general, though sweeping, in his condemnation, and that if he will only point out our errors we will give his refutation equal prominence to the original statement. Mr. Manville ought to see that our condemnation was intended to be against a system, which system we believe to be utterly wrong, and that no personal imputation was or is made. We start our argument with the statement that "the whole system of tendering was a wrong one." We admit it was following precedent, and we say "The engineers at Dublin followed the rule, bad and condemnable as it is, and can only be said to have erred." As stated at the end of our article, we have no desire to do other than compel an alteration of this system, so that the position now stands:

1. We attack, or intend to attack, a system.
2. Mr. Manville assumes we attack him, while, in reality, there was not the slightest intention of so doing.
3. Mr. Manville says our "deductions" are incorrect. This is very immaterial, if the facts are correct. The best logician may err in his deductions, and we are not infallible.
4. Mr. Manville accuses us of making "serious insinuations" against him. If to say he has erred by following precedent is a "serious imputation," we accept the soft impeachment, though where the seriousness or the insinuation come in it is difficult to say.—Ed. *E.E.*]

TRANSFORMER DISTRIBUTION.*

BY J. SWINBURNE, MEMBER.

The distribution of electrical power by means of alternating-current transformers can hardly be considered to have reached its final state, and though it may be somewhat difficult to say what system will be in general use 10 years hence, there is little doubt that present practice will be largely superseded.

The method now in vogue is simple: it consists of running several independent dynamos, each with its own engine; each dynamo supplies a few high-pressure mains, which branch off, and supply transformers placed in the houses, or wherever light is required. This system, admirable for country towns or straggling villages, is hardly likely to be permanent anywhere else. It has many disadvantages. Except that all the dynamos and engines are in one building, it is nothing more than a collection of little independent installations. Each engine and dynamo supplies its own circuits, which are independent of all the others. In cases of a breakdown of an engine or dynamo, and in many cases of the leads, there is a stoppage till new arrangements can be made at the station. In addition to this, great lengths of high-pressure conductor are required, and this leaves openings for breaking down of insulation. The introduction of high pressures in private houses is dangerous if not well managed, and is in any case expensive, demanding compliance with all sorts of regulations, rendered necessary for the security of the public. The greatest drawback to the present system, however, lies in the waste of power in the transformers themselves. For a long time transformers were supposed to have an efficiency of about 98 per cent. More will be said on this subject presently.

It must be borne in mind that in spite of the drawbacks of the present system of putting transformers in houses, it may be, and probably has been, advisable for electric light companies to begin on that system, even in such places as London; but I do not think such an arrangement will pay in the long run, and a time will arrive when the mains will have to be changed and a low-pressure supply system substituted. When an electric light company begins, it has to take on houses here and there, where it can get them; but if its district is populous and wealthy, it should soon be enabled to work on some low-tension or sub-station system; and then the question is whether it is not better to lay the low-pressure mains at first, instead of beginning on one system and changing to another. Probably none of the existing companies mean to change from one system to another. Their engineers have no doubt gone into the merits of the particular cases, and have come to their conclusions with great deliberation, and I do not think it well to offer any criticisms lightly.

Parallel Running according to Orthodox Hypothesis.

To begin at the beginning of my somewhat extensive subject, the first question is that of running machines in parallel. There are few matters of greater importance to engineers, and few on which opinions differ so widely. One says that machines will not run in parallel unless they have large self-induction; another, that it is necessary to have iron in the armatures; another that they will only run together if they have no self-induction, or as little as possible. Others say that there is no difficulty in running them in parallel. No engineer who employs direct currents denies the advantages of running machines in parallel; if independent running is advisable in alternate systems, it is equally advantageous in the case of direct currents, and direct-current stations should have separate circuits for each little district, each district being run by one dynamo. I do not think, therefore, independent running is advisable.

---

* Paper read before the Institution of Electrical Engineers.

In 1884 Dr. Hopkinson showed that alternate-current dynamos could be run in parallel, or could be run as dynamo and motor, and even that a machine giving a high pressure could be run as a motor off a circuit of lower pressure. In his paper he assumes that machines have "self-induction." He points out that the self-induction varies, but that it would be impossible to work out the calculations if the "self-induction" were taken as variable. For some reason or other, Dr. Hopkinson's calculations have received little application. That is to say, engineers have not taken actual cases and worked them out. Calculations have been made in which the various quantities have appeared in the form of letters, and diagrams have been drawn in which they are represented by lines whose lengths have been chosen at random. The geometrical treatment of many problems of this kind shows most of the actions very clearly to students, but is not always of value in practical work, as in most cases some lines are so long and others so short that it would be difficult to avoid large errors. The result of this is that few of us, if any, have had a definite idea of how much "self-induction" a machine should have to make it work well in parallel with others. The general impression is that it is somewhat difficult to design a machine whose "self-induction" is large enough, and that most failures to run in parallel are due to deficiencies in this respect. I am using the term "self-induction" under protest, as I prefer to look at the question from another point of view. But whatever goes on in a dynamo, if the no load E.M.F. is treated as constant, a value for a constant coefficient of self-induction can be assumed which would produce results somewhat similar to those found in practice. To overcome the difficulties arising from deficient self-induction in the armature circuit, Dr. Hopkinson has proposed to insert it artificially, in the form of choking coils, or to use induction couplers to compel synchronism. Without knowing that it had been done before, I described a similar arrangement to the Institution a few years ago.

In the spring of 1890 Mr. Mordey read a most important paper, in which he described some experiments on alternate machines. He argued from them that self-induction was deleterious, and that machines would run together best if they had none. In the discussion, Dr. Hopkinson pointed out that the experiments were quite in accordance with his theory, and that there was nothing that could not be foretold by it.

To begin with, it is necessary to get a clear idea of what is required for parallel running. It is not exactly the same as the case of alternating motors, neither is it the same as two machines of equal pressure coupled in parallel by themselves. If all the machines are coupled to two main conductors, we may consider them one at a time, and take each dynamo as coupled to a system whose pressure and variations of pressure are independent of it. Suppose the effective pressure to be 2,000 volts, for example: we have to consider a pair of mains with 2,000 volts, and we have to couple on a dynamo to add so many amperes to it. Such a machine must be excited to give 2,000 volts on no load, being then thrown into circuit with full steam turned on immediately afterwards. It should be excited to give somewhere about half load with 2,000 volts at the terminals, and should then be thrown in. Steam can then be turned on, and the excitation raised to its normal value. The machine should be so designed that any excessive power that the engine may give shall not only not throw the machine out of step, but shall not increase the armature current to such an extent as to damage the insulation by excessive heating.

The power absorbed by a dynamo working on a parallel system is

$$P=\frac{B^2 r}{2 i^2}-\frac{A B r}{2 i^2}\cos 2\pi n\tau+\frac{A B L}{2 i^2}\sin 2\pi n\tau,$$

where A is the maximum station E.M.F.—that is to say, the station pressure is A $\sin 2\pi n\tau$—B is the maximum "impressed" E.M.F. in the armature, r is the armature resistance, i the impedance of the machine, and τ the angle of lead. This equation is taken from Dr. Hopkinson's paper. When the dynamo is doing its proper share—that is to say, under normal conditions—

$$B=I c,$$

where I is the impedance of the whole circuit when the machine is isolated, and working at full load on an external resistance, and c is the maximum value of the current. To find how much the driving power may increase for a small increase of current, we may differentiate with respect to c, and then find the value of L which makes the result a maximum.

$$c=\sqrt{\frac{A^2+B^2-2AB\cos 2\pi n\tau}{i^2}}.$$

$$\operatorname{Cos} 2\pi n\tau=\frac{A^2+B^2-i^2c^2}{2AB}.$$

So,

$$\frac{dP}{dc}=\frac{ABr}{2i^2}\cdot\frac{i^2c}{AB}+\frac{AB\,2\pi nL}{2i^2}\cdot\frac{d\sin 2\pi n\tau}{d\,2\pi n\tau}\cdot\frac{d\,2\pi n\tau}{d\cos 2\pi n\tau}\cdot\frac{d\cos 2\pi n\tau}{dc};$$

and in the case of a dynamo working on resistance, or on a station load when supplied with just its right share of power,

$$\cos 2\pi n\tau=\frac{A+rc}{B},$$

$$\text{and } \operatorname{cosec} 2\pi n\tau=\frac{B}{Lc}.$$

So,

$$\frac{dP}{dc}=\tfrac{1}{2}A+cr,$$

c being the maximum, not the effective current. It will be observed that L has disappeared altogether.

This shows that for a very small increase of power the increase of current will be the same, whatever the self-induction of the machine may be. It would not matter if the machine had none. A machine with no self-induction would (Mr. Mordey notwithstanding) short-circuit the mains if the engine supplied too little power; in fact, at full load it would be giving its minimum possible output, and any attempt to diminish this would be disastrous.

Discussing the question of a very small increase is not exhaustive; an engine may supply a large proportion more than its share of power to one machine. For instance, suppose it supplies twice the normal power. Many engines could not give such an excessive power, but in others which have expansion gear controlled by a speed-governor it is easy to get double power if the station is running at a slightly slower speed than that for which the governor is set.

These matters are always made much clearer by taking practical examples and working them out. The great difficulty is to obtain accurate data. I should prefer to discuss such machines as those described in Mr. Mordey's paper read here a short time ago. Without wishing to say anything in disparagement of his excellent paper, I must point out that an account of experiments should contain full particulars of the machines on which the experiments were made. Such omissions are exceedingly common in electrical papers. Mr. Mordey has not given us the details of the field magnets, air space, armature coils, or exciting coils; he has not even given us the currents in the different experiments. I have found similar omissions whenever I have tried to gain information from any of the numerous experiments which have been made on alternate machines in America. Mr. Mordey does, however, say that about half the drop in his machines is due to resistance, and half to self-induction. The machines give an output of 2,000 volts and 20 amperes, and when fully excited give 2,200 volts at no load. This would correspond to a self-induction of 0·05 henry.

Suppose, first, that the self-induction were such that $2\pi n L=r$: on increasing the power supply, the effective current increases evenly, and when the power supplied to the machine is doubled, the effective current is only about 44 amperes. It is necessary, however, that the machine should stand decrease of load, as well as increase, without injury. Keeping the same self-induction, let us decrease the load to zero with the full excitation on. The current gradually diminishes to just below 15 amperes, and then increases to just over 20 again.

These figures are extremely troublesome to work out from Dr. Hopkinson's equations, as the angle is so small that an error in about the sixth place of decimals will vitiate the results.

Many people prefer diagrams such as those used in mathematical books when dealing with harmonic variations. Mr. Blakesley has applied these diagrams to the discussion of alternate dynamos and motors, and Messrs. Kapp, Fleming, and others have applied them too. The chief drawback is that it is not always easy to draw such figures to scale. They are generally drawn with the values taken at random, to give ideas of the principles involved. So far as I know, no scale diagram of this sort has ever been published. In the case of the 40,000-watt machine such diagrams can be applied; but with 100,000 machines, which will probably be the standard size, the diagrams are almost illegible.

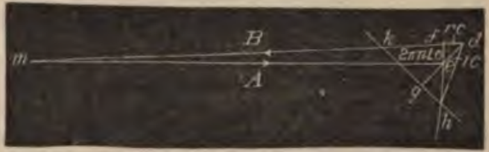

FIG. 1.

Fig. 1 is a diagram to scale. The lines are all rotating positively. The diagram is made as follows: The pressure in the mains, A, is drawn first. Instead of the maximum, it is simpler to draw the effective pressure—in this case 2,000 volts. From the end e, $2\pi n L c$ is drawn at right angles to it to f; and then $r c$ from f, parallel to A, B, is drawn to join the ends of A and $r c$, as shown. The lines are all pressures, but the instantaneous current is in step with the pressure $r c$ and with the pressure A, so that the power is proportional to B $r c \cos f d m$. I use the expression "in step" to mean co-phasally synchronised. Thus two machines may be running at the same speed without being in step, just as soldiers may take the same number of paces per minute without being in step.

To find the current at double load, produce $i c$ to g, so that $d g=2 i c$. Through g draw a straight line cutting B at k, at an angle, $g k d$, equal to the angle $d e f$. The line $g k$ is the locus of the end of the line representing the pressure spent over the resistance and self-induction of the armature with currents giving double load. It is unnecessary to go into the proof of this. With

m as centre and A as radius, describe arc cutting kg at h; join dh. Then the current at double load is to 20 amperes as dh is to de. In this case the double-load current is not much more than 40 amperes.

To find the current at half-load, bisect de, and through point of bisection draw a straight line parallel to hk, and proceed as before. The no-load line, of course, passes through d.

Let us now assume the self-induction to be 0·05. The resulting diagram is shown in Fig. 2. The double-load current is almost exactly 40 amperes.

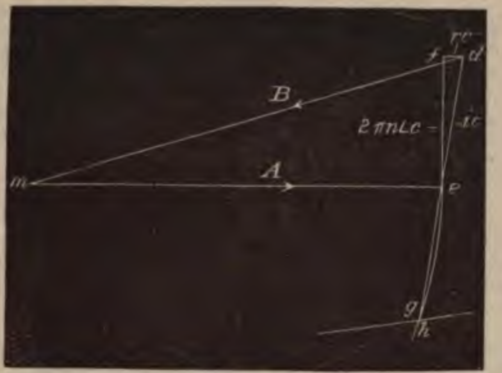

FIG. 2.

Take now the case of a 10,000-watt machine with a self-induction of 0·1. At double load the current is 50 amperes, and at no load it is only 1·6 amperes. If the machine has a self-induction of much more than 0·1 quadrant, the current at double load begins to increase rapidly. It is thus clear that the self-induction may have any value between 0·008 and 0·1 and the machine will work perfectly in parallel.

We have only taken small machines. Mr. Kapp recently described a 60,000-watt machine with an armature resistance of 1·74 ohm, and a self-induction of 0·0955—say of 0·1. We may see how it will work in parallel. The pressure is 2,000 volts, and the frequency 80. This case cannot be shown clearly in a diagram, as rc is very small in comparison with $2\pi n Lc$ or B. The result is, however, that the machine cannot possibly take double power from the engine; it falls out of step first. Now 60,000 watts is not a large output for central stations, and it is probable that 100,000 will be about the size adopted. The "time constant" of such a machine is considerably greater. We thus find that according to the self-induction hypothesis the difficulty does not lie, as commonly supposed, in getting enough self-induction in the armature; the trouble is that there is generally too much. But in machines from 25,000 to 50,000 watts it is exceedingly difficult to make dynamos that will not run perfectly in parallel, so great is the permissible margin of self-induction. It must be carefully borne in mind that so far the armature has been supposed to have a constant coefficient of self-induction, and the pressures of current are assumed to vary harmonically.

The orthodox hypothesis thus tells us that with ordinary sizes of machines it is exceedingly difficult to design them so that they will not run in parallel. Either, therefore, all ordinary machines run perfectly in parallel, or the assumption that alternating currents follow sine laws, that machines have coefficients of self-induction constant throughout each period, or that they have coefficients of self-induction constant for different armature currents, is too far from the truth to be useful; or, in legal language, one or some or any or all of them must be wrong.

(To be continued.)

PHYSICAL SOCIETY.

The annual general meeting of the above society was held on February 13, Prof. A. W. Reinold, F.R.S., past president, in the chair.

The reports of the council and treasurer were read and approved. From the former it appears that there has been a satisfactory increase in the number of members and in the average attendance at the meetings. During the year a translation of Prof. Van der Waal's memoir on "The Continuity of the Liquid and Gaseous States of Matter" has been issued to members, and it is hoped that the translation of Volta's works, now in hand, will be published before the next general meeting.

The council regret the loss by death of Mr. W. H. Snell and Mr. W. Lant Carpenter, and obituary notices of these late members accompany the report.

The treasurer's statement shows that the financial condition of the society is very satisfactory, and that the sales of the society's publications have increased considerably.

A vote of thanks, proposed by **Mr. Whipple** and seconded by **Dr. Gladstone**, was unanimously accorded to the Lords of the Committee of Council on Education for the use of the room and apparatus.

Dr. Atkinson proposed a vote of thanks to the auditors, Prof. Fuller and Dr. Fison, which was seconded by **Dr. Thompson** and passed unanimously. The proposer, in referring to the satisfactory nature of the accounts, recommended that the publications of the society should be brought before physicists and other students of physical science, and Dr. Thompson heartily concurred in this recommendation.

A third unanimous vote was accorded to the president and officers for their services during the past year, the proposer and seconder being **Dr. Waller** and **Prof. Minchin**.

The following gentlemen were declared duly elected to form the new council: President, Prof. W. E. Ayrton, F.R.S.; vice-presidents, Dr. E. Atkinson, Walter Baily, M.A., Prof. O. J. Lodge, D.Sc., F.R.S., Prof. S. P. Thompson, D.Sc.; secretaries, Prof. J. Perry, F.R.S., T. H. Blakesley, M.A., M.Inst.C.E.; treasurer, Prof. A. W. Rücker, M.A., F.R.S.; demonstrator, C. V. Boys, F.R.S.; other members of council: Shelford Bidwell, M.A., LL.B., F.R.S., W. H. Coffin, Major-General E. R. Festing, R.E., F.R.S., Prof. G. F. Fitzgerald, M.A., F.R.S., Prof. J. V. Jones, M.A., Rev. F. J. Smith, M.A., Prof. W. Stroud, D.Sc., H. Tomlinson, B.A., F.R.S., G. M. Whipple, D.Sc., James Wimshurst.

The meeting was resolved into an ordinary science meeting, and Messrs. W. Thorp, B.Sc., G. W. Yule, and S. Joyce were elected members of the society.

A paper **"On the Change in the Absorption Spectrum of Cobalt Glass Produced by Heat,"** by **Sir John Conroy, Bart., M.A.**, was read by Mr. Blakesley. The absorption spectrum of cobalt glass when cold consists of three dark bands in the red, yellow, and green, with a considerable amount of absorption between the first two. When a piece is heated to nearly red heat, the absorption between the first two dark bands diminishes, and the band in the red moves towards the least refrangible end of the spectrum, whilst those in the yellow and green retain their position, but become less distinct. During the heating of the glass the intensity of its colour diminishes, and as the glass cools its original colour and absorption spectrum returns. Diagrams and numbers showing the character and positions of the bands in hot and cold glass accompany the paper, together with the numbers obtained by Dr. W. J. Russell (*Proc.*, Royal Society, 32, p. 258) for cold cobalt glass. In conclusion, the author says that these observations, and those of Feussner on solutions, show that the absorption spectra of some substances vary with temperature. In solutions, this may be due to formation of different hydrates, or to partial dissociation, but in a solid like cobalt glass an actual change in its chemical constitution at a temperature considerably below its fusing point does not seem probable. **Dr. Gladstone** said it was generally known that heat affects the colouring power of substances, and that in solutions absorption is greater the higher the temperature. Different solvents sometimes produce effects analogous to heat, for cobalt salt dissolved in water and in alcohol give pink and blue solutions respectively, and rise of temperature makes the aqueous solution more blue. He concurred with the author as to the causes of the phenomena in liquids, and that the same explanation would not apply to glass. **Prof. S. P. Thompson** thought Sir John Conroy's results agree with the experiments which Mr. Ackroyd showed before the society some years ago, when he demonstrated that the colours reflected by opaque bodies, such as porcelain, etc., when heated, tends towards red. **Prof. Minchin** showed some experiments in illustration of his paper on "Photo-Electricity," read at the previous meeting. In one of these, a seleno-aluminium battery, illuminated by the light of a taper, deflected an electrometer needle, thereby actuating a relay and ringing a bell. He afterwards exhibited one of his "impulsion cells" in action, and showed the change from the insensitive to the sensitive state produced by a Hertz oscillator at a distance. During the discussion, **Mr. Tunzelmann** said Kalischer and Von Uljanin had worked at the same subject, the former being the first to make experiments on a photo E.M.F. in selenium. His cells were made by winding brass wires on glass tubes and coating them with selenium, which was subsequently annealed. These cells lost their power after some time and would not respond to feeble lights. By using two wires of different metals he obtained better results. Fritts, in 1883, used brass and gold plates coated with selenium, and Uljanin employed platinum plates deposited so thin as to be transparent. The latter experimenter found that the E.M.F. was proportional to the square root of the intensity of the light. He also observed that the orange-yellow of the prismatic spectrum produced the greatest effect, whereas the yellow-green and the green rays of the diffraction spectrum gave the maximum E.M.F. Comparing these results with Langley's observations on the energy of the spectrum, it would appear that the E.M.F. bears no relation to the maximum energy falling on the surfaces. Speaking of the cause of the phenomena, he said the electrolytic idea of Von Uljanin seemed inapplicable to Prof. Minchin's results, and he enquired whether a mixture of selenium and aluminium would undergo a gradual change by exposure to light. **Dr. Gladstone** said such a change, if it occurred, would be very slow, for nearly all difficult chemical reactions take time to complete. The fading of colours was adduced as an instance of slow chemical change produced by light. **Dr. Waller** thought the subject might throw light on the changes occurring in the retina, and asked if it was possible to separate thermo-electric and photo-chemical effects? **Dr. Burton** said he had suggested that the action of light on the retina was a photo-chemical one some time ago; but hitherto it had been difficult to obtain substances sensitive to any but the blue and violet rays, whereas the eye was most sensitive to green and yellow light. In the photo-electric batteries, however, the E.M.F. may generate a current, and, therefore, energy, and the important question seemed to be: Where does this energy come from? Is it a chemical change precipitated by the action of light, or does a direct conversion of light and electric energy occur? **Prof. Minchin**, in his reply, said he thought his cells really transformed the incident energy. They were usually kept on open circuit, and there appeared to be no deterioration with time, the only change being a sluggishness in developing their maximum E.M.F.

BIRMINGHAM.

The following is the report to the Birmingham City Council of the Public Works Committee:

This committee report that by section 22 of the Birmingham Electric Light and Power Order 1889, the Corporation are required to appoint and keep appointed one or more competent and impartial person or persons to be electric inspectors for the purpose of inspecting electric lines and works, and of certifying meters under the order. The testing places and instruments for testing the mains and services are to be provided by the undertakers, the number of stations and their distance from the mains to be fixed by the Corporation, or in case of dispute to be settled by the Board of Trade. The undertakers are also to provide upon all premises from which they distribute electric energy suitable and proper instruments, approved by the Board of Trade, for recording observations; the instruments and the records to be open to inspection by the inspector. The inspector, when required to do so by the Corporation, shall test the mains, and, when required by a consumer, shall test the service lines, for insulation and conductivity. He is to give notice to the undertakers before commencing any tests, who may be represented thereat, and on the day after such testing he is to deliver a copy of his report thereon to the undertakers. All expenses of such testing, including reasonable fees to the inspector, are to be paid by the undertakers, unless the inspector's report show that the authority or person was unreasonable in requiring the test to be made, when the expenses and fees shall, on application by the inspector, be ascertained by a court of summary jurisdiction and paid as directed by the court. The inspector is also to certify the meters to be used, and any difference between the undertakers and their consumers as to the correctness of any meter is to be settled by the inspector. The fees to be paid for testing the mains, service lines, etc., and certifying meters, are to be prescribed by the Corporation and approved by the Board of Trade.

ABERDEEN.

REPORT OF THE GAS SUB-COMMITTEE.

Mr. Alexander Smith, manager of the Corporation Gas Works, has, in compliance with the request of the Gas Sub-Committee, prepared a report on the expense of erecting an electric lighting station to supply the compulsory area, and the probable annual revenue that would be derived therefrom. The consumers in the compulsory area (which comprehends Union-street from the Townhouse westwards to Bridge-street, Market-street between Union-street and Guild-street, and St. Nicholas-street), whose yearly accounts for gas are over £5, consume 27½ million cubic feet of gas per annum. To replace this, 600,000 units of electricity would be required. On the assumption that one-fourth of these consumers would take electric light in place of gas, 150,000 units of electricity must be generated yearly. Mr. Smith has been in communication with Mr. W. B. Esson, electrical engineer, London, and taking into account that the machinery will require to be of greater power to meet the demand in winter, Mr. Smith finds that dynamos having an aggregate capacity of 2,000 16-c.p. lamps would be necessary. He accordingly recommends that two machines of 1,000 lights each be obtained, leaving space for additional machines to be put in as they may be required. Each dynamo would be driven by a compound engine of 150 h.p. For providing steam to the engines, three water-tube boilers would be erected, one to be kept as spare. The cost of distributing cables, opening ground, etc., would be at the rate of 32s. per yard. The charge of 9d. per unit of electricity is the maximum allowed by the provisional order.

Mr. Smith then gives a statement of the probable cost of erecting the necessary buildings and laying down the plant, and of the estimated revenue and expenditure. The cost is as follows:

Engines, connections, water-heaters, lifting apparatus, dynamos, and controlling apparatus	£2,800
Boilers and economisers	1,700
Storage cells	3,500
Meters	1,600
Distributing cable, including street boxes for leading off service lines	4,200
Buildings, machinery, foundations, and boiler settings	3,500
Ground	3,000
Incidents and utensils	1,000
Total	£21,300

The annual revenue is estimated thus—150,000 units of electricity at 9d. per unit, £5,626; meter rents, £150—total, £5,875.

Mr. Smith estimates the annual expenditure at £4,556. 10s., leaving an estimated profit of £1,318. 10s. The expenditure is made up by allowing on storage cells, interest, and sinking fund at the rate of 5½ per cent., and for depreciation, repairs, and renewals 15 per cent.; on meters, interest, and sinking fund at 5½ per cent., and for depreciation, etc., 10 per cent.; on machinery, interest, and sinking fund at 5½ per cent., and on depreciation, etc., 10 per cent.; on buildings, interest, and sinking fund at 5½ per cent., depreciation, etc., 5 per cent.; on ground, interest, and sinking fund 5½ per cent. Fuel is estimated to cost £575; wages and management, £600; water and taxes, £120; incidentals, £150.

The profit of £1,318. 10s. is brought out on the assumption that 150,000 units will be sold. Whether this quantity is disposed of or not, the whole of the expenditure will remain the same with the exception of fuel, oil, and water, and assuming that only 100,000 units were sold, the above profit would not only be wiped out, but over £350 of annual loss would be shown. He is, therefore, of opinion that it would be advisable, before laying down so expensive works and machinery, to ascertain the number of consumers that may be expected to take a supply, and whether there is any likelihood that the estimated quantity of electricity will be disposed of. Mr. Smith then makes the statement that the cost of electricity supplied to the estimated number of consumers in the compulsory area would be, as above stated, £5,875, and that these consumers would receive the same lighting power in gas for the sum of £1,350.

In the event of the Town Council not proceeding themselves to erect a station, Mr. Smith mentions that Mr. Esson recommends that offers from electrical companies should be invited by advertisement, with a view to one of those companies becoming transferees of the Corporation for the purpose of undertaking all their obligations with respect to electric lighting. This course has been followed by the Corporation of Glasgow.

In conclusion, Mr. Smith gives the comparative cost of two different qualities of gas with one Board of Trade unit of electricity. This shows that while one Board of Trade unit of electricity costs 9d., 48 cubic feet of 28 c.p. gas (equal to one unit of electricity) would cost (at the rate of 3s. 8d. per 1,000 cubic feet) 2·112d., and 54 cubic feet of 25 c.p. gas (equal to one unit) 2·376d.

COMPANIES' MEETINGS.

CITY AND SOUTH LONDON RAILWAY.

The following is the report of the Directors:

It is with much satisfaction that the Directors have to report that the railway has been completed, and was opened for public traffic on 18th December last. The running of experimental trains suggested the necessity for a number of minor improvements in the tunnels and working appliances, the carrying out of which caused some delay; but on the 4th of November the completion of the line was graciously inaugurated by H.R.H. the Prince of Wales, accompanied by H.R.H. the Duke of Clarence. This ceremony was followed by several weeks' private running of the trains, so that the staff might be fully instructed in their somewhat novel duties, and on the 18th of December the railway was opened to the public. Since that date a service of trains, running at intervals of about five minutes, has been maintained, and although there have been a small number of occasional delays, from the failure of engines and other causes, there is every reason to be satisfied with the use of electricity as a motive power, and when the various improvements, suggested by experience, are all carried out it is anticipated that the line will prove one of exceptional safety and comfort, and will be worked with economy and regularity. During the short time the railway has been working the average number of passengers carried has been about 15,000 per day, but as the weather improves, and the line is better known, this number will no doubt steadily increase. It has been found in working such a rapid service that the siding accommodation provided is insufficient, and arrangements are now in progress for the construction of additional sidings at the Stockwell terminus, which will add greatly to the facilities for working the line. The Board of Trade have recommended the addition of a fourth engine and dynamo to the generating plant at Stockwell depot, and these have accordingly been ordered, and it is intended also to add two additional trains and four additional locomotives to the rolling-stock. As soon as these additions are complete, it will allow of a considerable accession to the number of trains run, and the opening of the line on Sundays, if thought desirable. The accounts for the past half-year have been made out in the form previously adopted, but as the Company is now recognised as a railway the accounts in future will be rendered in the form prescribed by the General Railway Acts. As the line was only opened a few days before the close of the half-year, it has not been thought necessary to create a separate revenue account for that short period. With the view of developing the traffic on the line, a Bill has been deposited in Parliament to authorise the construction of a branch line from King William-street to the Bank, and thence under Moorgate-street, Finsbury-pavement, and the City-road to The Angel at Islington. It is anticipated that this line, when made, will bring upon the existing railway a large additional traffic during that period of the day when the trains are at present not well filled, in addition to being itself a remunerative undertaking, will add greatly to the value of the present railway, as affording access to the heart of the City traffic, and a much-needed direct communication between the northern and southern suburbs of London. The calls upon 26 shares having been long in arrear, a formal resolution will be proposed confirming the forfeiture of the shares, and authorising their being dealt with. The Directors retiring by rotation are Mr. Walter Robinson and Mr. Sampson Hanbury, who are eligible for re-election. The Auditors also retire, but offer themselves for re-election

The thirteenth ordinary general meeting of this Company was held at Winchester House on Tuesday, the Chairman, Mr. Charles Grey Mott, presiding.

The **Secretary** (Mr. H. H. M. Smith) having read the notice convening the meeting,

The **Chairman** said: Gentlemen, I propose to take the report as read if no one has any objection. In moving its adoption, I have the pleasure of meeting you at last with an opened line, a completed line, and a line earning and at work. Now you all know that in new undertakings of this kind, where so much is new and so little can be got by experience of the past, there is always the feeling of uncertainty that however much you may have studied the question, however much care you may have taken in the commencement of your works and in all the arrangements that you are making, there may yet be something which you have overlooked, which, after all, may render all your labours and all your care of no effect. Now, in an undertaking so new in all its parts as this has been, we were specially open to such a possibility. I am thankful to feel that we have in the experience of this line since its opening the satisfaction of knowing that no serious defect in our calculations has been apparent. I consider that for a new line, new in construction, new in working, new in all its arrangements, it is an unqualified success. Now, if you look back upon the past and what we have gone through for the moment, you will recollect that the construction of this line was one that had never before been adopted. We successfully overcame all obstacles, and we have a line that has been, so far as we can see at present, satisfactorily constructed. There may be certain points, and there will no doubt be certain minor points, in which improvements can from time to time be made, but, as a whole, we can congratulate ourselves that the line, as far as construction goes, has turned out satisfactorily. The next and most important question was the motive power. You know, we were told that electricity was new for a thing of this kind, and that it probably would fail. A great many objections were taken outside to the course that we proposed to adopt, and I confess it was with very considerable anxiety of mind that I and my fellow Directors had to come to you and recommend the adoption of a system which was entirely and absolutely untried. It is satisfactory to feel that we have not been disappointed. The success of our running of these engines (electrical) has been most decidedly marked. We have had no serious drawbacks. You have seen in the papers a great deal about the breakdowns upon this railway, but I venture to say that with such a new system, and such an enormous number of trains as we have run, that it is surprising that those breakdowns have been so few and unimportant as they have. We have carried 900,000 passengers since we opened at Christmas, or two or three days before, in perfect safety. We have run our engines and trains 60,000 miles over the line. We have received in money about £7,500, or equal to 15 passengers per train mile. Of course, in a metropolitan system like this, you expect a very large number of passengers per train mile; very different to the number on a great system like the North-Western or the Great Western, where the number is only 3 or 3½. But, considering that this is so new, that we have absolutely never advertised the line in any way, that we have only dealt with the traffic that has come to us, and we have been compelled to deal with, considering that, I think that we may say that our traffic on the whole has been very satisfactory. We have not encouraged it, we have not tried to draw traffic to the line, because we felt that the first thing was to work the line with the traffic that came to us satisfactorily; that we were not justified in encouraging traffic until this was the case. Therefore, you must not be surprised if the receipts of the line are not as much as perhaps we had hoped, and as we have not the slightest doubt they will be in the future. You will no doubt wish that I should say something about the expenses of the line if I can. Well! I don't feel justified in making any definite statement upon that subject. You must know that at the commencement of a line of this kind we have had to go to a great many extra expenses, because we had to make security doubly sure. But as the line is now settling down into more steady working, we are from week to week reducing these expenses, and finding out small economies from day to day. We have had such a short experience of the cost of working at the present moment, that it would be utterly wrong in me to give any approximate statement on the subject. But I may say this, that as regards the motive power, I feel quite sure that when we come to settle down properly, we shall find that the cost of werking this line by electricity will be decidedly cheaper than working it by steam. Now the receipts of the line per train mile run I can deal with, because that is an ascertained fact at the present moment. Our actual receipts per train mile have been 2s. 6d. The receipts on large railways, such as the North-Western and Great Western, amount roughly to something under 5s. per train mile. That is double what our receipts are at present. But you must remember, on the other hand, that the trains that we are running are only about one-fourth, perhaps one-fifth the weight of the trains which are run upon these lines; and that, therefore, we have really, weight for weight, nearly double the actual earnings per train mile of these lines. I have good hopes and expectations that we shall raise our receipts per train mile to a similar amount to that earned on these lines—viz., 5s. and then you will see at once that we stand in a much better position to deal with our traffic, having only one-fourth the weight to move to earn the same money that they get. I hope that when we next meet we may be able to deal definitely with the cost of working this line. But as the accounts cannot be made up to-day, and we have only some five or six weeks' traffic to deal with, I cannot give you accurate information as to receipts and expenditure. We have found that we could work the lines more economically, and with greater regularity in every way, if we had additional sidings underground. Of course, we did not know until we tried what was absolutely requisite on this head, and we therefore propose, as mentioned in the report, to construct some additional sidings at the Stockwell end of the line. At present we shall construct a small portion of the Clapham extension, which will serve as sidings, and form part of that line. Therefore the money won't be wasted. The Board of Trade suggested that we should have a fourth engine and dynamo in our engine-house at Stockwell. We have three now, two of which work the line, while the other is in reserve. But looking at all the possible risks connected with electricity, of which no one has very accurate knowledge at the present day, we thought it better to comply with the Board of Trade suggestion, and we have therefore ordered another engine and dynamo, and they are now in course of construction. When they are finished we shall have double the power that we ordinarily require. If ever we carry out the Clapham extension that engine will come into use, and the cost will all be part of the same expenditure, and will afterwards be a saving. We find, also, that we are short of rolling-stock, and want a little more in order to multiply the number of trains. You know that at certain times, morning and evening, our trains are overcrowded. We are gradually increasing the number of trains at those times, and we hope to give such a service very shortly as will completely deal with all the traffic comfortably and satisfactorily. But to do that we must have more rolling-stock, and we have therefore ordered additional engines and carriages. I dare say those who have had experience of undertakings of this kind know that when the line has been constructed there is generally a difficulty between the company and its contractors, which, unfortunately, too often ends in legal proceedings, and a long and expensive arbitration or lawsuit. Our contractors, as is usual in such cases, made certain definite claims upon us for extra works, about which there was, as there usually is, difference of opinion between our engineers and them, which might have resulted in a long and expensive lawsuit. Not desiring to have such contentious matter and to waste money in that way, we had a friendly conference with our contractors, and I am glad to say that on thoroughly discussing the affair we have arrived at a settlement which has been approved by both parties. I refer, of course, to the contractors for the construction of the line, and not to the other works, such as rolling-stock, etc., which are not yet completed. We have settled the whole thing with them, and arranged as to the payment of all the balance due to the contractors. That is satisfactory—we have no law proceedings, and we leave off with satisfaction on both sides.

Now I had better deal with the question that is in the report, and that is the extension of the line to Islington. I confess for my own part, and my feelings are shared by the Directors, that if we could have avoided extensions we should done so. We got the power for the Clapham extension, but we have not exercised it, and do not intend to do so until we are satisfied that it will add to and improve our present line. But we found in working this line that there were certain things which, using our best judgment and discretion, did make it desirable that the line should be extended in the direction which we now propose to ask Parliament to grant us powers for. We have, of course, learnt a great deal in the last few months as to the probable traffic and the future of this line, and we have used the knowledge derived from that information for the benefit of the concern, as far as it was capable of being used ; and we have come to the conclusion that it is desirable in your interests, and in the interests of the development of the traffic of this line, that power should be asked for that extension, and that it should be made. We have certain difficulties to deal with with regard to our City traffic at the present moment which this line (the extension) would help us to get over, and we want the middle of the day, as well as the early morning and evening, filled up by traffic for which we have abundant room, and for which all expense has been gone to. We don't think that can be entirely filled up by the district where the line now is. It must come from a more populous area. We have chosen a line and a district for the extension where the traffic is enormous, and which I feel satisfied, from our present knowledge, will prove a very remunerative undertaking itself. But, in addition to this, it will bring upon this line (the City and South London) exactly the traffic of which we are deficient. I think you should approve of this proposed extension. Of course, in approving the Bill you are not approving the carrying out of the works. If we obtain the Act we have to come to you for your consent to carrying out the works. It is merely a question of obtaining the Act if we can.

There are a few shares, as you will observe in the report, upon which the calls have not been paid. Some of these have since been claimed and the calls paid up, but certain others (15) are not likely to be paid up, and we have therefore no alternative but to declare them forfeited. We can do nothing with them until they are. I now beg to move the adoption of the report.

This was seconded by **Mr. Hubbard**.

Mr. J. Drake was glad to hear the line was now out of the range of experiment, and that the motive power was absolutely satisfactory, and complimented the engineer (Mr. Greathead) on the result. He would like to see the Clapham programme carried out. He also referred to the courtesy of the Secretary in answering questions when applied to for information. He thought the big scheme (Islington extension) required consideration. He did not want the small scheme to be swamped by anything of the gigantic proportions indicated.

Mr. Sydney Shepherd asked if it was possible to enlarge King William-street Station, so as to provide two sidings instead of one?

Mr. Tress Barry wanted to know whether the new locomotives to be ordered, could be made strong enough to draw more carriages than the present ones, or whether the latter could draw more weight than they did? He also asked for the cost of obtaining the proposed Act?

The **Chairman**, in replying, said he was afraid King William-street Station could not be enlarged. They could not lengthen it because of the Monument. They had the matter under consideration, were quite aware of the difficulties, and would be very glad if they could see their way to deal with that station. As it stood it was not capable of being greatly improved. That was one of the questions which were involved in the proposed Extension Bill. The service approach to the station was exceedingly bad, everyone having to pass over one of the worst crossings in the City, and that did them damage. They proposed, if they got the Extension Act, to give access to the station in the other part of King William-street, near Lombard-street, so as to avoid this crossing. In further reply to Mr. Shepherd, the **Chairman** said that the engineers were considering whether they could alter the platform so as to take four cars instead of three.

In reply to Mr. Barry, he said that in ordering their new engines they were considering the question of getting some additional power out of them. He did not anticipate that the Act for the extension would be very costly. They knew now all the opposition against it. He then put the motion, which was carried unanimously.

Resolutions were then passed re-electing Messrs. Walter Robinson and Sampson Hanbury directors, and the auditors Messrs. Turquand, Youngs, and Co., and forfeiting the shares mentioned above.

The extraordinary general meeting, which had been adjourned from the 3rd inst., was then held, to approve of the Bill for the Islington extension.

The **Chairman**, having made a few remarks of a similar character to those reported above, moved a resolution approving the Bill.

This was seconded by **Mr. Hubbard**.

Mr. Court, as the shareholder who was responsible for the adjournment of the previous meeting, stated that he had since conferred with the chairman and engineer, with whom he had gone fully into the matter. He now thought the scheme would be for their benefit, and supported the motion.

Mr. Broad opposed it.

Some discussion ensued, but eventually the motion was carried by a majority.

Mr. Broad demanded a poll, but on **Mr. Court** stating that he represented £80,000 of capital, and the **Chairman** remarking that they had 19,000 shares in their favour as against 2,000, Mr. Broad withdrew his demand.

Another resolution was passed giving the Directors power to take permissive powers in the Bill to make the extension a separate undertaking with separate capital.

A vote of thanks to the Chairman, proposed by **Mr. Godfrey** and seconded by **Mr. Broad**, closed the proceedings.

WESTMINSTER ELECTRIC SUPPLY CORPORATION.

The fourth ordinary general meeting of the shareholders of this Company was held at the offices, 32, Victoria-street, S.W., on Wednesday morning, the chairman, Lord Suffield, presiding.

The report stated that at the present time current was being supplied to the equivalent of about 12,000 lamps of 8 c.p., formal applications had been signed for about 17,000 more, and numerous enquiries continued to be made for the supply of current. The central station in Millbank-street had been running continuously day and night since November 13, 1890. Current was being supplied from this station throughout the whole length of Victoria-street, in various parts of Pimlico, and also to the Houses of Parliament. The work of laying the mains, like that of building, was seriously hampered by the severe weather. Notwithstanding this, since the work was started in February, 1890, mains had been laid along about 16 miles of roadway, and these included a total length of about 75 miles of "ways," into which about 40 miles of copper had been drawn.

The **Secretary** (Mr. Frank Iago), having read the notice convening the meeting, and the minutes of the last meeting,

The **Chairman** said : I presume the report (the gist of which is given above) will be taken as read. Although I am sorry to see so few shareholders present, still I may say that nothing can be more satisfactory in my opinion, and that of the Directors, than the affairs of the Company. This dreadful weather has no doubt stopped a great many from coming. I wish it had been otherwise, for I think what I have got to say will be acceptable to all. The report, which has been sent to each shareholder, will have already made you acquainted with the fact that the business of the Corporation is going on satisfactorily. Since our last general meeting, on the 5th of November, the Millbank-street central supply station has been completed, and current has been supplied therefrom continuously, day and night, in a most satisfactory manner. It frequently occurs that when a station is first opened some unexpected flaw, either in the machinery or in the mains, is brought to light, causing a serious breakdown, but I am happy to be able to inform you that this has not been our experience. Some slight irregularities in the light did occur for a few days, but this was before we got on to the batteries. Since then the light has been perfectly steady and satisfactory, notwithstanding the unusual demand throughout the whole of several days in consequence of fogs. You will hardly need to be told that fogs, however unpleasant they may be from a sanitary point of view, are, from an electrical point of view, a very different matter. We find that our heaviest loads come in during fogs, so that to us they are a source of profit instead of loss. I am glad to be able to inform you that since taking over the Millbank-street station from the builders we find that we have every reason to be satisfied with the work, and that the building is in every way suitable to our requirements. Here I may say that a very distinguished engineer, Sir Wm. Thomson, went to see that station, and—I am saying it on the authority of Sir Douglas Galton—he not only expressed himself perfectly satisfied, but I think he said it was one of the best he had ever seen. We have now sufficient plant and machinery erected there to supply all the lights likely to be required for that district during the next six months, and as the demand increases so shall we increase our machinery. I may here point out a great advantage which the Westminster district possesses over many others, which is, that within it are a number of offices, in addition to private houses and shops, and that these offices, requiring as they do to be lighted in the winter months through many hours each day before the chief part of the lighting of the private houses comes on, enable us to use our Millbank-street station to great advantage. We are at present supplying from the Millbank-street station some 9,000 lamps of 8 c.p. each. The cost of running at that station is now about £60 per week. This includes the cost of coal, water, stores, salaries, and wages. To this has to be added £90 per week for maintenance, depreciation of machinery and mains, establishment charges, rent and sinking fund on buildings, etc., making in all £150 per week. At the beginning of the month of January, the income per week for current supplied had already reached £150, which has now increased to £200, so that even in this early stage a profit is already being made. Of course, as the days lengthen, the same ratio will not be kept up ; nevertheless, it is to be noted that though the days have been lengthening of late, and the demand for current has, in the case of other companies which have been longer established, been falling off in consequence, our receipts have augmented. This is, of course, attributable to the increased number of lights which are daily being installed in the district, or, at any rate, partly so. The temporary station in Dacre-street, at the back of these offices, which is supplying the remainder of the lamps on circuit, has been of great service to us, in enabling us to supply current to the western portion of our district while the station at Eccleston-place was being built. In a few days the Eccleston-place station will be delivering current, and the temporary station will then be closed as soon as possible. I may tell you also, gentlemen, that I, together with a good many of the shareholders and the Directors, visited Eccleston-place as well as the other new station in Davies-street, and we were very much gratified with the progress that has been made. At our Davies-street station great progress has been made, and from there we expect to be supplying current by the end of next month. Had it not been for the severe and prolonged frost, which brought all building operations to a standstill for two months, current would have been supplied from both Eccleston-place and Davies-street before now. You will observe, by looking at the map on the walls, with what rapid strides the work of laying the mains has proceeded since you were last called together. There were then about 11 miles laid. To-day, notwithstanding interruptions, there are about 18 miles completed. This includes the principal streets throughout the district, in which there is the greatest demand. The others will be completed in the order in which the demand arises. I should mention that our consumption of coal already bears favourable comparison with that of the most economical of the older established companies, and that when the condensing plant, now on order, is erected, which, in the case of the Millbank-street station, will be in the course of the next two months, a still greater saving will be effected. Now, gentlemen, as to the question of capital and expenditure. You will see from the accounts sent with the report the expenditure under the different heads to December 31 last. Owing to the demand for light caused by the stoppage for about two months or more of the supply of the only other company having powers in the same district as ourselves, it was considered desirable by the Board to increase the amount of copper in the mains, especially in the Mayfair district, for which large numbers of applications have been received. This has largely increased the expenditure on mains, but, of course, will result in the earlier sharing of profits, as we shall be enabled to take on a much larger number of lights without delay. The Board are pleased to say that so far the whole of the works, whether of buildings—and I draw your particular attention to this because I think it is a most important point—mains, or plant, have been carried out well within the estimated cost, and that the total cost of the works to give enough current to supply the whole of our districts for some time to come, will not exceed the amount of capital asked for in the original prospectus of the Company—viz., £300,000. The amount actually subscribed was £214,765, in 42,953 shares of £5 each, leaving a balance of £85,235, in 17,047 shares of £5 each. To provide for the extra cost of laying mains, completing the present work in hand, and making provision for any extra work the Board may consider it desirable to enter upon, they suggest to the shareholders that the Directors be empowered, at their discretion, to issue all or any part of the 17,047 shares, the balance remaining unissued. They feel justified in asking them (the shareholders) to increase their holdings, as there is no doubt of the future financial success of the undertaking. Well, gentlemen, you don't know me perhaps, and I don't know how you should, but I tell you that I would not make this statement if I did not believe it to be absolutely true. The Directors have also passed a resolution to issue, if required, £100,000 debentures at 5 per cent. interest, to run for a term of 10 years, but not to a greater extent than an amount of one-third of the share capital for the time being.

I may now say, and I think it is gratifying, that the calls on the shares have been very well paid up. Out of all the calls that have been made, there remains only a small balance to be paid up, which I have no doubt will be forthcoming very shortly.

I now beg to move the adoption of the report and accounts for the past year. If any shareholder has any question to ask, we shall be pleased to give him every information in our power; and I believe that we can give him all the information that can be required.

Mr. Boulnois, M.P., seconded the resolution, and, referring to the working of the Board, said that he could assure the shareholders that though they had many discussions, they had no differences, and since he had had the honour of a seat at it, the proceedings had been conducted with the utmost unanimity. As to the staff, he was sure he spoke the thoughts of his co-Directors when he said that it was impossible that any staff could exhibit more ability, more zeal, and more loyalty than theirs from the highest to the lowest. They were especially happy in having so able an engineer as Prof. Kennedy, and equally happy in having a manager like Capt. Bax, and an active secretary like Mr. Iago. He thought there was a very great future in store for that Company if the shareholders would have confidence in the Directors.

Mr. Wm. Cooper asked as to the item on the credit side of the balance-sheet, £3,957. 2s. 8d., "expenditure applicable to future business," and to what it referred. Was it not properly chargeable to capital, or whether it should be in the revenue account?

A **Director** explained that it referred to work done which would be remunerative in future years, such as getting customers, travelling expenses, advertising, and organising the staff. It could not be placed to capital account, because it was not a capital charge. It would be written off in future years, but they had not resolved at what rate. At a future meeting an account would be given of it.

Mr. Rogers Wallis asked if any steps had been taken to get a provisional order conferring greater facilities in the northern portion of St. Margaret's parish, and as to the issue of debentures.

The **Chairman** answered the first question in the affirmative, and as to the debentures, said they were in no immediate necessity, and did not intend to issue them at once. They issued them in accordance with the articles of association, which gave them power so to do.

Mr. Brown Martin pointed out there was a very great advantage in issuing debentures at 4 or 5 per cent., instead of 7 per cent., which they might anticipate having to pay on fresh capital, so that they saved 2 per cent. for the benefit of the shareholders.

Prof. Kennedy, in answer to a question, said that at present they were paying their way with the earnings from the Millbank station, and the comparatively small number of lights supplied from there.

The **Chairman** then put the resolution adopting the report and accounts, which was carried unanimously.

Resolutions were next passed authorising the Directors to issue the remaining shares, and re-electing the Auditors, Messrs. Cooper Bros. and Co.

A vote of thanks to the Chairman and Directors brought the meeting to a close.

BELL'S ASBESTOS COMPANY.

The third ordinary general meeting of this Company was held at the Cannon-street Hotel on Monday afternoon, Mr. John Bell, chairman, presiding.

The **Secretary** having read the notice convening the meeting,

The **Chairman** said: Gentlemen, as the report and accounts have been in your hands for some time, I will consider them as read, and will just make some observations upon the leading items in the accounts. The bills receivable, stated at £10,273. 12s. 4d. as on December 31, have about three-fourths of them fallen due, and, as a matter of course, have been paid. I say as a matter of course, because they would not occupy their position in the accounts next to the cash—they would not be allowed by the Auditors to do so—if there had been any reasonable doubt with regard to them. All of you who have any experience of an audit by Messrs. Cooper Bros. and Co. know perfectly well that all such things as allowance for bad and doubtful debts, writing off from plant or stock, and so forth, are always strictly and severely attended to. A very full allowance has been made for bad and doubtful debts, and, therefore, the £31,723 is as good as the bills to which I have just referred. The stock has grown during the last year from two causes. We made some purchases in advance of our requirements, which we considered to be of a very advantageous nature for the Company, and the decline in the trade mentioned in the report has caused an accumulation of stock; but everything that is old and obsolete—and there is very little of that—has been put down at nil. You may take it that the general principle is that the stock is valued simply at cost price. There never was a sounder figure in the assets of any Company than this £51,599 in the balance-sheet placed before you to-day. With reference to buildings, plant, and machinery, fittings, fixtures, and so forth, you will recollect that when this business was taken over by this Company it was stipulated that the plant and machinery should be purchased at the price at which it stood in the books of John Bell and Sons, subject to an independent valuation, and an independent valuer estimated them at double the amount, or thereabouts, at which they were taken over by the Company. That was due to the severe writing down that had taken place during many previous years, and that same severity in writing down has been continued by the Directors of this Company as a going concern, and therefore plant, machinery, etc., £6,837, are a very good asset. The asbestos estates in Canada were purchased by the Company from John Bell and Sons at the exact price at which that firm had acquired them, and that fact, as it was a magnificent purchase they (the Company) had made, was part of the consideration for the goodwill paid to that firm. The mines at the present day are worth vastly more than the sum paid for them and the total goodwill put together.

The two other items (expenditure on account of 1891 and expenditure on new buildings) are so small they are not worth talking about. The £40,000 premium on new shares transferred is placed in the profit and loss account, not for the purpose of swelling that account, but because the Directors had no option in the matter. It was laid down in the articles of association that this premium must be especially placed in the profit and loss account, and that is the reason it is so placed, and for no other cause. I have never considered it my duty to enter into newspaper discussions about the affairs of this Company; I have always considered it to be the reverse of my duty, and therefore I have not replied to various criticisms made at different times. I have felt rather inclined to let calumny die out. But in deference to the wishes of many of our best friends, and especially of many of our best customers, I must say some very plain things indeed upon what lies at the bottom of the decline in our trade during the past year. A year ago it was my duty to lay before you the system on which we follow the very common practice of giving gratuities to those who have the practical handling of the goods we sell. I told you, in words which could not be honestly misunderstood, that we had never given a penny to any man to cover inferior quality or shortness of weight or measurement; that in no sense or degree had we ever corrupted any man by a bribe or inducement to do wrong. You gave your sanction to our action in this matter, and very soon after the First Lord of the Admiralty stated in the House of Commons, in reply to a question, that our name had, on this account, been removed from the list of contractors to the Admiralty. Had we been asked whether we had anything to say for ourselves, we should have been able to reply that during our 10 years' dealing with the Admiralty we had never given a penny to any servant of that department, that no mark stood against us for failure of our material under any circumstances, and that we had never been wanting in weight or measurement to the extent of a single gramme or millimetre. We could have added that the most important forms in which asbestos is used in the navy had been first designed and worked out to practical use by us, at the expenditure of time, labour, and money. But no such question was put to us, and, as was not unnatural, the belief became general in the public mind that such a denunciation in the most public place in the world, in language of marked severity, by a person of high position and responsibility, was the result of an official investigation by means of which we had been convicted of corrupting public servants. It suited, and still suits the purpose of previously very unsuccessful trade rivals to propagate and foment, by many devices, the idea that we are not as honourable traders as they. A certain section of the so-called financial press have been useful allies of our trade rivals in furnishing specially dished-up articles and paragraphs which zealous commercial travellers have brought under notice in thousands of places where, but for their efforts, such papers would never have been heard of. Set going by so powerful an authority as the First Lord of the Admiralty, the crusade against us became fashionable, and gained strength as it proceeded. The sowing of wicked calumny broadcast became easy of accomplishment, and has been fortunate in achieving such success as all efforts on the part of its chief promoters to rival us in the excellence of our manufactures and in the success of our trade had utterly failed to attain. We have to own to-day that what fair competition could not do, persistent detraction in private and in public has accomplished, the result being that in the last year we have lost a large amount of trade. I shall endeavour to show you, not by dry reasoning on abstract principles, but by an appeal to your own every-day experience, that to point to this Company as something out of the common, and to make up against it a charge of bribery and corruption, is outrageously unjust; and I hope to leave on your minds a conviction that having stood so well, as we have stood, the first heat of the onslaught, we shall eventually come out of this contest chastened, but not vanquished, and we shall regain our former hold of the first position in our trade, which, though it has been shaken by the events of the past year, no one has yet been able to wrest from us. Thus, I shall hope to justify the belief expressed in the report, that the decline in our trade will not be permanent. I have declared to you, but let me, by repetition, emphasise the declaration, that we have never given a penny to any man to cover defect of quality, or of short weight or measurement. No man has ever ventured to say that we have, though there are those who would be glad to be able to say so. True, we bow to the rule of "backsheesh," as it is allowed to prevail in all countries and among all sorts and conditions of men. It is not enough to say none are too low for it: we must also say none are raised above it. Bribery and corruption are not so allowed to prevail; the humblest despise them as sincerly as the highest. But gratuity-giving in an infinite variety of forms, though nowhere commended, is everywhere practised without reproach to him who gives or to him who receives. Take an instance or two. A railway porter secures for you, to the exclusion of some-one else, a comfortable corner seat and gets sixpence; but the man opposite to you has given somebody half-a-crown so that he may travel first-class at third-class fare. You have given an unlawful gratuity which cannot be defended on abstract principle; but nobody accuses you of bribery and corruption, as they rightly do the fellow opposite to you. The good sportsman, respected merchant, esteemed director of the great railway and steamship companies—even a noble lord (if he be not one of the Admiralty)—when he sells a horse gives a sovereign—sometimes more—to the groom of the buyer. Why does he give this unlawful gratuity if he honestly believes the animal is all that he has described him to be? Why, he follows a custom, and he feels himself safer in doing so than he would if he kept the money in his own pocket. Who dreams of accusing him of bribery and corruption? In the shooting season the moors of Scotland are crowded with directors, managers, superintendents, and all sorts of people who can influence or give out orders. They are not on the moors at their own expense. Luxurious yachts career over the seas filled with such men, also not at their own expense. Here is a vast use of what, strictly speaking, is undue influence to gain a trade object. But who calls it bribery and corruption? Who ever proposes to strike his host's name from a list of contractors because of it? Yet, if I give a weekly-wage earning mechanic a couple of sovereigns to help him to afford his family a summer holiday at Blackpool or Margate, up go your eyes and out comes the Pecksniffian howl against bribery and corruption. Your solicitor—I know my friend Mr. Stibbard has always been one of the exceptions which prove the rule—gets a commission when he influences you to insure your life or property in a particular office. Some bankers get a return of brokerage when they employ a stockbroker to invest your funds. Some great railway companies tip forwarding clerks to secure a preference of goods traffic for their lines. Makers of steam engines propitiate the man who is to drive a new engine just laid down. Even these remarks of mine will, in certain places, be favourably commented on, or the reverse, according as we are liberal or otherwise in purchasing copies of certain journals for distribution. One more example in a region where one treads with reverential care—the region of high justice. When commercial companies go into liquidation, it often happens that an eminent public accountant is appointed by the court to carry on the business, and such official manager finds that he has to fall in with this practice of gratuity-giving, or the business would come to a deadlock. He applies for and obtains the sanction of a judge. This, of course, could not be if all gratuity-giving for the furtherance of business was bribery and corruption. I might occupy much more of your time in pointing out scores of facts in your own every-day experience, showing "backsheesh," which is universally admitted to differ from bribery and corruption, is used throughout all grades of society to further the ends men have in view. But why dwell on what is in every man's conscience? My point is not that gratuity-giving is right, but that Bell's Asbestos Company is not different to other men, that we are in the common swim, and that this fact must come to be realised as a fact. And thus men will see that we are more sinned against than sinning, and that as the public judgment in regard to us regains its balance, we shall gain the trade that has been, without due cause, withdrawn from us. Some of you shareholders in this company are employers of labour, and users of steam power. If you wish to do away with this system of gratuity-giving, you must do something more effectual to the purpose than transferring your account from us to some other concern. You must go below the surface, and recognise that this matter has its root in the never-ending struggle between capital and labour, that it is an outcome of the determination of every man to use any power he possesses to get something beyond the bare necessaries of life, and if you don't like the form of it, set yourselves to provide a substitute for it. We (the Directors) are anxious to find this substitute, and we are ready to co-operate with any set of employers who will honestly deal with this question on the human, not the Pharisaic principle. Now, gentlemen, shareholders in this Company, do your part. Let no man in your presence venture to accuse this Company of bribery and corruption. Tear the mask away wherever you meet it, and assert your Company as better able to face the world than any of its traducers. Do this boldly and constantly, and you will soon have your dividends over 20 per cent. again. Let us now pass on to the Canadian properties of the Company. The use of asbestos in the manufacture of steam packing and as a non-conductor in various forms has greatly grown, and the consumption has completely caught up the supply obtainable from such mines as are in efficient working at Thetford and some less important outside places, but no new application of the material calling for large quantities of it has come to light. For the present trade the mines now in work can furnish what is required, and the remunerative prices which have now become established will sufficiently stimulate production at those mines to meet the growing demand until some new use of asbestos calls for larger quantities than can be supplied from the present sources. We have not abandoned, as certain busybodies have alleged, our Bellmina and Hayden estates. We have them in reserve, and when the growth of our trade requires us to break into new ground your Directors will not hesitate to do the work. Meanwhile we shall be content to make money quietly and safely at Thetford. We have made very important forward sales of the estimated surplus of crude asbestos over our own manufacturing requirements during the present year. I am under engagement to the buyers not to mention quantities or prices, but I may venture to state that these sales will, with ordinary good fortune in the working, give us a very much larger profit than has hitherto been obtained from ours or any asbestos mines. It is true the effect of these sales will be somewhat watered by previous contracts at much lower prices, the fulfilment of which to some extent runs into the present year. It is also probable that the fact of there being a quantity deliverable by us at comparatively low prices has militated against our obtaining so high a value as we should otherwise have secured. I am, however, very sure that our policy of dealing freely at the prices obtainable in the natural course of our trade is the right policy, and we have done so well on these present contracts that regret is out of place. The income now being derived from the Thetford mine places the value of that estate at a higher sum than was paid to the Company for all the properties and goodwill of the business taken over. We are very desirous of strengthening the Board by the addition of a member possessing the necessary experience and influence to make a real acquisition to the Company. The kind of man we want is much occupied and difficult to get. We want a man whose knowledge, experience, and influence count for something among steam users, and a man who will be satisfactory to our altered list of shareholders. We are in very full communication with a gentleman of first-rate commercial standing, and of the sort I have just described, and I hope that we shall soon be able to make an announcement on this subject, which cannot fail to be satisfactory to the shareholders. In this matter the Directors have given special attention to the change which has taken place in our list of shareholders. Our shares have now passed out of the few hands in which they were held in large blocks, and, instead of a trifle over 300 shareholders to whom we allotted, we have now 900 members or over. This altered condition of our share-list may, and probably will, bring about important changes. One beneficial change that we look for is that, as small shareholders take more direct interest in their investments than great ones, therefore the spread of our stock into many hands will strengthen our Company in many ways and advance its trade. I beg leave to move "That the report of the Board of Directors and the Auditors, and the financial statement, submitted to this meeting, be, and the same are hereby, approved, adopted, and confirmed."

This was seconded by **Mr. T. B. Lightfoot.**

Mr. Atkinson hereupon rose and put a series of 12 questions, which had been printed and circulated in the room.

Mr. Hirsch asked if Mr. Atkinson was a shareholder, and after some discussion it came out that he was not on the register, but had had one share given him by a friend who, he stated, had lost several hundred pounds over the Company. The Chairman was thereupon requested not to answer, and Mr. Atkinson was asked to remove himself. Which, however, he did not do.

Mr. Ridley (a shareholder) then rose, and said he would put the questions, and Mr. Hirsch again urged the Chairman not to answer them, stigmatising them as impertinent.

The **Chairman**, however, said there was no difficulty in answering the questions, and proceeded to show that there was practically no foundation for any of them. To the major portion he gave a direct negative, only refusing to answer those concerning the internal management of the Company. He then put the resolution, which was carried unanimously, that is, if we exclude Mr. Atkinson as a dissentient.

Resolutions were then passed approving a dividend of 5s. per share free of income tax, making, with the interim dividend, a total of 15 per cent. for the year; re-electing Mr. T. B. Lightfoot as a director; and Messrs. Cooper Bros. and Co. as auditors.

A hearty vote of thanks was accorded to the Chairman and Board on the proposition of **Colonel Wortham**, seconded by **Mr. Hirsch**.

MANCHESTER EDISON-SWAN COMPANY, LIMITED.

An extraordinary general meeting of this Company was held on Monday at the Victoria Hotel, Manchester, for the purpose of considering the advisability of obtaining additional capital by the issue of debentures or otherwise.

Mr. Vernon K. Armitage, chairman of the Company, who presided, explained that the meeting was called in accordance with a promise made by the Directors that the shareholders would be consulted before any scheme involving any considerable expenditure of money was entered upon. As he had informed the shareholders on a previous occasion, there had recently been a very marked diminution in the demand for small installations of the electric light, and the Directors thought that in view of the large number of provisional orders which had been recently granted to local boards and corporations, it was desirable that they should have the ability, if they had the opportunity, to do such large work as the carrying out of such provisional orders would involve. The Directors felt that if they were placed in a position to raise such money as they might consider necessary, there was a future for the Company, especially in a place like Manchester, where a provisional order for electric lighting had been obtained. By the articles of association the Directors had full power to raise what money was required on debenture or by call, but in accordance with the promise they had made they desired to secure the assent of the shareholders before going forward. With reference to the general position of the Company, he added that he thought there was not the smallest doubt that for the current year they would make 7 or 8 per cent. on the capital that had been called up.

In reply to a question by Mr. F. B. Ross, the **Chairman** stated that it was not yet known what amount it might be necessary to raise. That would depend altogether on the extent to which they were entrusted with orders.

Some discussion followed, at the close of which, without any formal resolution being passed, it was left to the Directors to obtain such additional capital as they consider necessary.

LIVERPOOL ELECTRIC SUPPLY COMPANY.

The annual meeting of this Company was held on Tuesday in Liverpool, Mr. Arthur Hill Holme, chairman, presiding.

In their annual statement of accounts the Directors reported that the amount of net profit available for dividend was £4,878. 9s. 6d., and out of this sum they recommended a dividend of 3½ per cent., which would absorb £4,074. The expenditure on capital account during the year had been £54,019. The number of lamps supplied from the Company's stations on January 1, 1890, was 6,700, and on January 1 of this year 11,750. It was anticipated that during the present year there would be still greater progress in this direction, with corresponding advantage as regarded profits. The Directors had applied for parliamentary powers to extend the present area of supply to London-road, Prince's-road, Prince's-park, and Sefton-park. The assent of the Toxteth Local Board had been given, but the Liverpool Corporation withheld their assent, as the Directors were unable to accept the conditions which were sought to be introduced into the draft order.

The **Chairman**, in moving the adoption of the report and statement of accounts, remarked that the Company had made a considerable addition to their business during the past year. They had also adopted all the latest improvements in electric lighting, and everything possible had been done to secure a good and steady light. In this they had succeeded, with the result that they were now giving their customers a supply of electricity second to none in England. They had increased their number of fixed lamps from 6,700 to 13,074, although they had engines of sufficient power to supply 25,000 lamps. The Directors had written off a sum of 3 per cent. for depreciation on all underground mains laid since the commencement of the Company, including those which were not yet in use. Serious thought had been expended on a project for extending the business of the Company, and, as stated in the report, they were contemplating carrying the electricity to London-road and to Prince's and Sefton Parks. They had had considerable difficulty with the Corporation as to a provisional order for London-road, but permission for the other areas had been readily granted by the Toxteth Local Board. The Directors saw the importance of taking the light to London-road, for there was a demand for it, and they would have difficulty in extending their business if an opposition company occupied so important a position as London-road. The necessity of making a call upon the shareholders would probably not occur before January next, and then the call, it was anticipated, would not exceed 10s. per share.

Sir David Radcliffe seconded the Chairman's motion, which was unanimously agreed to.

Messrs. Von Sobbe and Samuel H. Holme were then re-elected as Directors; and the remuneration to the Directors was, on the proposal of Mr. Charles Birchall, increased from 150 to 250 guineas.

HASTINGS ELECTRIC LIGHT COMPANY.

The annual general meeting was held recently at Hastings, Mr. H. M. Baker, chairman, presiding.

The Company has made a net profit of £543. 13s. 6d. (including a balance of £97. 0s. 11d. brought forward from last account) for the nine months ending December 31. A dividend of 5 per cent. has been declared. To provide for supplying incandescent lights under their order, the Company have issued £2,000 worth of 5 per cent. debentures. They have received more applications for lights than they can fulfil until they have the new machinery. The Directors not having hitherto received any remuneration, a resolution was carried voting them £200.

COMPANIES' REPORTS.

TAUNTON ELECTRIC LIGHTING COMPANY.

The following report of the Directors was presented at the shareholders' meeting on Wednesday:

Your Directors herewith present the fourth annual report of the Company, together with the audited balance-sheet. The number of shares allotted is 2,556, on which the sum of £12,780 has been received. During the year the new buildings in St. James's-street, referred to in the last annual report, have been completed. These buildings, with the new machinery and plant laid down, make the works of the Company quite a model depot. But the completion of these works took a much longer time than had been anticipated; and during the early part of the year there was the expense, for a time, of running two works, in consequence of which the cost of coal and other items was very much higher than would have been the case under normal conditions. Further than this, the work of the construction of the new circuits in the town was much delayed in consequence of the stringent requirements of the Board of Trade; thus retarding the whole business of the Company for several months, during the most important part of the year, for constructive work. Under all these exceptionally adverse circumstances, it will hardly be matter for surprise that the accounts show a deficit on the year's working of £438. 17s. 5d.; but now that the works are in good order, and the business of the Company constantly increasing, there is every reason to believe that the next year's working will show a different result. Towards the close of the year it was found necessary to obtain more capital than the issue of ordinary shares secured, and your Directors therefore determined to issue £5,000 debentures, such sum to include the previous issue of £3,000; and they confidently appeal to the present shareholders to come forward and take up this issue of £5,000 debentures. Since the issue of the last annual report, Mr. John Withycombe has resigned his seat on the Board of Directors, in consequence of his having gone to reside at Minehead. Your Directors appointed Mr. Arthur A. Chapman to fill the vacancy thus created, and they ask the shareholders to confirm the appointment. The Directors who retire by rotation are Messrs. Alfred Lewis, H. G. Massingham, and A. Stevens; the two former offer themselves for re-election. The auditor, Mr. Albert Goodman, retires; but being eligible, offers himself for re-election.

ST. JAMES AND PALL MALL ELECTRIC LIGHT COMPANY, LIMITED.

Directors: Eustace J. A. Balfour, Esq., chairman; Latimer Clark, Esq., F.R.S.; Egerton H. Clarke, Esq.; H. Woodburn Kirby, Esq.; Sir John H. Morris, K.C.S.I.; Charles Showell, Esq. General manager and secretary, James Strick. Chief engineer, S. T. Dobson, Assoc.M.Inst.C.E., M.Inst.E.E. Auditors, Messrs. Deloitte, Dever, Griffiths, and Co. Solicitor, Sydney Morse.

Report of the Directors and statement of accounts for the year ending 31st December, 1890, to be presented to the shareholders at the meeting to be held at Winchester House, Old Broad-street, E.C., on Monday, March 2, at three o'clock.

The Directors in submitting their annual report for 1890, with accounts as certified by the Company's Auditors, congratulate the shareholders on the satisfactory progress made by the Company during the past year. At the commencement of the period under review, the number of lights connected amounted to the equivalent of about 4,460 8-c.p. lamps. This number gradually increased up to the 30th September, when the number of lamps connected amounted to about 12,150. In the last quarter of the year remarkable progress was made, and on the 31st December the lamps connected amounted to about 26,500, and this total has since been increased to about 30,000. On the 23rd July last, a prospectus was issued inviting subscriptions at par for 3,670 ordinary shares. All these shares have been taken up, the bulk of them being subscribed for by the Directors and their friends, the shareholders subscribing for a very small number. On the 9th January, the balance of the original issue of shares—viz., 980—was allotted. These subscriptions have enabled the Board practically to complete the existing station, which is now in every way working satisfactorily. Of the £50,000 debentures, which, as will be seen from the accounts, were outstanding on the 31st December, £43,000 have since been converted into ordinary shares under the powers contained in the articles. On the conversion of the balance of £7,000 of the debentures, the capital account of the Company would stand as follows :

19,980 ordinary shares of £5	£99,900
100 founders ,, £1	100
Making a total of	£100,000

The conversion of these debentures places the Company in a position to at once raise moneys for the purposes of the northern station, which the Company has to erect to satisfy the requirements of the district covered by the provisional order granted by the Board of Trade, and approved by Parliament during its last session. The question of the amount of damages payable by the contractors for delay was referred by consent to the arbitration of Mr. J. Fletcher Moulton, Q.C., who awarded the sum of £1,806. 11s. 6d. to the Company for loss of income. The Directors being of opinion that this sum represents the equivalent of depreciation up to the 31st of December, 1890 (a large part of the machinery having been in work for but a short period), have written this amount off capital expenditure. By reference to paragraph 2 of this report it will be seen that the station has practically been at work for three months only in 1890, and that the dividend has been earned during that period. The Directors have, therefore, after consultation with the Company's Auditors, charged £963. 3s. 1d., being one moiety of Directors' fees and management salaries for the year, to capital expenditure. On Statement III. it will be seen that the account of capital is charged with £65,981. 11s. 9d. as expended to December 31st, 1889. The balance-sheet at that date displays that this sum is made up of capital and general expenditure from which is deducted a small sum received for current supplied, etc. During the first six months of the year the Company's revenue showed a debit of £183. 7s. 11d. During the last six months the profit amounted to £5,161. 8s. 8d., which, after deduction of the debit referred to, leaves a balance of £4,978. 0s. 9d. to be dealt with. Of this sum £2,412. 8s. has been provided for payment of interest, and out of the balance of £2,565. 12s. 9d., the Directors recommend a dividend of 5s. per share, free of income tax, on the 9,000 ordinary shares in existence on the 31st December, 1890, absorbing £2,250, leaving a balance of £315. 12s. 9d. to carry forward. The experience gained since September has satisfied the Directors that the shareholders possess a very valuable property, which will yield a large steadily increasing income on their investment. The Directors regret the loss of their esteemed colleague, Mr. James Hemmerde, who died in the autumn of last year; they have, under article 84, appointed Mr. Egerton H. Clarke to a seat on the Board in his stead. Two of the Directors—namely, Mr. Eustace J. A. Balfour, the chairman, and Mr. Latimer Clark, F.R.S.—retire under clause 79 of the articles of association, and, being eligible, offer themselves for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths and Co., also retire, and, being eligible, offer themselves for re-election. Referring to the notice of the extraordinary general meeting on page 2, should the shareholders adopt the suggestion of the Directors to increase the capital of the Company by the creation of 7 per cent. preference shares, it is the intention of the Directors to offer 10,000 of such shares to shareholders now on the register in the proportion of one preference share to every two ordinary shares. It being necessary to alter the articles of association to entitle this Company's shares to a quotation on the Stock Exchange, the Directors have taken the opportunity to remodel them.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.

The twenty-seventh annual report of the Directors states that the accounts for the year show a net profit of £113,681. 4s. 8d., after charging the interest on the debentures. To this sum must be added £37,483. 7s. 3d. brought forward from last year, making a total of £151,164. 11s. 11d. From this amount is deducted the interim dividend of 5 per cent., paid July 15, 1890, amounting to £22,410, leaving £128,754. 11s. 11d. to be dealt with. Of this sum the Directors propose to distribute a dividend of £1. 16s. per share, absorbing £67,230, being at the rate of 15 per cent., and making, with the amount already paid, a total dividend for the year of £2. 8s. per share, or 20 per cent., leaving £61,524. 11s. 11d. to be carried forward to the next account.

PROVISIONAL PATENTS, 1891.

February 16.

2798. **Improvements in solutions and salts for electro-deposition and other purposes** Henry Joseph Altman, 44, Bolton-road, St. John's Wood, London.

February 17.

2834. **Automatically recording the value of shots upon targets by electric apparatus.** William Hallam Elton, 19, Belgrave-terrace, Exmouth.

2840. **An improved method of heating curling tongs or irons by electricity.** Arthur Henry Watson and Frank Emanuel Antonini, 4, Pall-mall, London.

2862. **Improvements in electric fire engines, also applicable to other electrically propelled vehicles.** Mark Wesley Dewey, 45, Southampton-buildings, London. (Complete specification.)

2866. **Improvements in electrical measuring instruments.** Henry Harris Lake, 45, Southampton-buildings, London. (Edward Weston, United States.) (Complete specification.)

2876. **Improvements in the application of electricity to various useful purposes.** Edward Robert Dale, 8, Quality-court, London.

2902. **An improvement in electric locomotives.** George Sylvester Grimston and Ernest Wilson, 28, Southampton-buildings, London.

February 18.

2986. **Improvements in apparatus actuated by electricity for stirring, and turning over malt and grain.** Edmund Edwards, 35, Southampton-buildings, London. (Julius Sandt and Heinrich Sturm, Germany.) (Complete specification.)

February 19.

2999. **Improvements in electric arc lamps.** Hubert Hallam Bigland and John Burns, 6, Lord-street, Liverpool.

3003. **Improvements in element for electric battery.** Ernest William Mayer, 71, Great Portland-street, London.

3030. **Improvements in propelling vehicles by means of electric motors.** Michael Radcliffe Ward, 12, Dacre-street, Westminster, London.

3049. **Improved circuit controller and alarm.** Claude Kennedy Mills, 23, Southampton-buildings, London. (Charles Morris Woolcott and Albert Edward Wilmont, United States.)

February 20.

3127. **Apparatus for automatically indicating loss or diminution of current in electric circuits.** William Cruyt, 433, Strand, London.

February 21.

3170. **Improvements in the manufacture of Leclanche cells.** Dan Rylands, Stairfoot, near Barnsley.

3191. **Improvements in the transmission of alternating differential phase currents.** Michael von Dolivo-Dobrowolsky and the Company Allgemeine Elektricitäts Gesellschaft, 47, Lincoln's-inn-fields, London. (Complete specification.)

3198. **Improvements in galvanic batteries.** Flavien Poudroux, 35, Southampton-buildings, London.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The receipts for the week ended February 20 amounted to £6,114.

City and South London Railway.—The receipts of this Company for the week ended February 21 amounted to £718.

Western Counties Telephone Company.—The Company have declared a dividend upon their preference shares at the rate of 6 per cent. per annum for the half-year ended December 31 last.

West India and Panama Telegraph Company.—The estimated traffic receipts for the half-month ended February 15 were £3,213, as compared with £3,585 in the corresponding period of 1890.

Western and Brazilian Telegraph Company.—The receipts for the week ended February 20, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £4,928.

London Platino Brazilian Telegraph Company.—It is intimated by the Company that the coupons on their debentures due March 1 next will be paid on presentation at the banking-house of Messrs. Glyn, Mills, and Co., Lombard-street, E.C.

NOTES.

Berlin.—There are now 100,000 incandescent lamps and 3,000 arc lamps burning in Berlin.

Bohemia.—The town of Chotzen, in Bohemia, is to have a central station for electric lighting.

Manchester Town Hall.—The proposed tenders for lighting this building has been left over until next month.

Civil Engineers.—Prof. J. A. Ewing, B.Sc., F.R.S., has been elected a member of the Institution of Civil Engineers.

Main Lighting in Hungary.—Tudor accumulators are being used for supplying electric light to trial trains on the Hungarian State railways.

Submarine Telephones.—Several ports on the coast of Sweden are intended to be connected by submarine telephone cable by the Government department.

Suakin.—A telegram from Cairo says the Sirdar recommends the erection of a telegraph line between Suakin and Tokar, a distance of 50 miles, showing that he considers the district safe against Dervish attacks.

French Accumulators.—We see it stated in French papers that the difficulties which were raised between the French Accumulator Society and the Tudor Company have been smoothed away—though in which direction is not stated.

Society of Arts.—On Wednesday next, March 11, at 8 p.m., Messrs. Newman Lawrence, M.I.E.E., and Arthur Harries, M.D., will give a lecture on "Electricity in Relation to the Human Body." Mr. W. H. Preece, F.R.S., will preside.

Female Electricians.—M. Marchand, a great advocate of female emancipation, just deceased, has, says *Electricité*, bequeathed a million francs for a college for the technical and professional education of women as doctors, lawyers, and especially electricians.

M. Gaulard.—According to the *Journal des Applications Electriques*, M. Gaulard went mad on account of the disappointment caused by the jury of the Exhibition of 1886 having given the diploma of honour not to himself, the inventor, but to the company who were introducing his transformers.

Durham and Amble.—A letter was read at the monthly meeting of the Durham Town Council from Messrs. Nicholson and Jennings with reference to electric light, but did not produce any comment. The Local Board of Amble received a similar communication, and the clerk was asked to apply for prices.

The Telegraph in Revolutions.—According to the *Petit Journal*, the telegraph was the cause of the failure of the Oporto revolution. Several telegrams to officials, stating that "The sick man will hardly last the night," were noticed, and the Government took alarm, did not deliver the telegrams, but watched instead, with the result known.

Norway.—Hammerfest, the most northerly town in Europe, is the first town in Norway, says *Industries*, to be lighted completely by electricity. The installation is on the Thomson-Houston principle, and the motive power is supplied by a waterfall at about a mile distance. The installation is satisfactory, and will be extended so as to light the harbour.

The Balancing of Engines.—At the Society of Engineers, Town Hall, Westminster, on Monday, Mr. Arthur Rigg delivered a lecture on "The Balancing of High-speed Engines," when the effect of the air-buffer in the Willans engine, and transmission of strains to the foundation, and the method of balancing an independent centre, were discussed.

The National Telephone Company opened an exchange at Leicester on Wednesday, when the through lines were used for the first time, and messages interchanged with Leeds, Bradford, Manchester, Liverpool, and other towns. Hitherto there has been no through communication with the North, the Postal Telephone exchange being purely local.

Anglo-French Telephone.—We have received the following latest official information as regards the London-Paris telephone line. The preliminary work of laying the cable began at Calais on Thursday. The submersion will take place on Friday (to-day) if weather permits. The land wires are not yet complete, but it is hoped they will be ready for service next week.

Madrid.—The Spanish Senate House has recently been lighted from the mains of the Electricity Supply Company for Spain, which has a large central station outside Madrid. The light was on Wednesday night witnessed by Queen Christina, who expressed great satisfaction with it. There are about 1,500 incandescent lamps in the building. The high-tension alternate-current transformer system is used.

Permanent Electrical Museum.—We are glad to see that a committee of the Institution of Electrical Engineers is to be appointed to fully consider the proposed permanent electrical museum in conjunction with the Institution. When, or if it is decided upon, we have a little information about several early and interesting electrical productions that we shall be pleased to put the museum committee on the trail of.

Royal Institution.—Prof. Victor Horsley, F.R.S., will give a discourse on "Hydrophobia" on Friday, March 20, in place of Prof. W. E. Ayrton, F.R.S., who is unable at present to give his promised lecture on Electric Meters, Motors, and Money Matters. To-day, Friday, before the Royal Institution, Albemarle-street, at 9 o'clock, Prof. J. A. Fleming, M.A., D.Sc., M.R.I., will give a lecture on "Electromagnetic Repulsion."

Gulcher Thermopile.—A Reuter's telegram, dated Berlin, March 3, says: "Herr Gulcher has invented a means for increasing the utility or efficiency of electricity by substituting thermal columns for dynamos, using nickel for the positive, and alloxate of antimony for the negative poles. The experiments in the matter have been conducted at the works of Messrs. Pintsch. The invention, however, is still in the theoretical stage."

Grimsby.—The following is the result of tenders for fitting up the Town Hall with the electric light, for the Grimsby Town Council: Crossley Bros., £815 (accepted). The town clerk, referring at the meeting of the Town Council at which the contracts were sealed, said the fitting up of electricity, including gas engine, would be £815, and the electroliers would cost £165 more. The proposed engine-house had been estimated at about £100.

Glasgow Athenæum.—A special type of steam boilers have been fitted up by Messrs. Lindsay, Burnet and Co., in connection with the electric light installation at the Glasgow Athenæum. They are of the firm's special dry-back tubular class for the higher pressures and for comparatively confined spaces, differing essentially from marine boilers in that there are no narrow, flat stayed spaces, which are so difficult to keep free of scale from bad water.

Chinese Telegraphs.—If it be true as reported, remarks the *Indian Engineer*, that the Chinese Government have extended their telegraph line from Yunan-Fu to Momien, direct overland communication between India and

Eastern China can be carried out in a very short time. Momien is distant from Bhamo only 135 miles and there should be no difficulty in linking the British and Chinese telegraph offices, as so short a distance now divides them.

Nottingham.—Writers in the local press are asking the reason why no steps are being taken to introduce electric lighting, and are urging the Corporation to immediately put itself in communication with one of the important companies who are prepared to supply electricity, saying that no doubt the town authorities would be able to arrange the matter on favourable terms. It is suggested that some independent member of the Council would take up the matter.

University Examiners.—Notice is issued by the University of London that on Wednesday, April 29, the Senate will proceed to elect examiners in the following departments (amongst others): Two in experimental philosophy, £210 each; present examiners, Prof. G. F. FitzGerald, M.A., F.R.S., Prof. Oliver J. Lodge, D.Sc., LL.D., F.R.S. Two in chemistry, £240 each; present examiners, Prof. H. E. Armstrong, Ph.D., F.R.S., Prof. W. A. Tilden, D.Sc., F.R.S.

Alnwick.—The Corporation of Alnwick have received an offer from Messrs. Nicholson and Jennings, of Newcastle, to put down an electric lighting station to supply as many arc lamps as are necessary for the streets, to fix lamp-posts, and maintain the light at a yearly rental, to include redemption of the plant in a term of years to be agreed upon, on a similar scheme to that upon which they are lighting Copwen (Blyth). The offer was referred to the Lighting Committee.

Crompton's Concert.—A smoking concert was held at Messrs. Crompton and Co.'s works by the Arc Works Athletic Club last Saturday evening. The concert was varied from the usual smoking concerts, being interspersed with toasts and speeches from members, and the chairman (Mr. Crompton). A distribution of prizes also took place to the winners of the athletic competition, and with the abundance of songs, recitations, cornet and violoncello solos a most enjoyable evening was passed.

Southampton.—The electric light company at Southampton are making active progress with the erection of their works. The streets were up last week with the construction of the culvert for the reception of the wires. The connection has now been made with the work done in the High-street, and the company are now excavating under the tramway line opposite East-street, to carry their wires to the other side of the High-street. The work is being done in a thoroughly substantial manner.

Old Students' Smoking Concert. — The Old Students' Association will hold a smoking concert on Saturday evening next, March 7, at Masons' Hall Tavern, Basinghall-street, City. Members of the O.S.A. will need no incentive to turn up; all old students at Finsbury or the Central who are not members should take the occasion and go, and the sight of so many well-known faces will doubtless induce them to join the association, and help its activity in this and also in more scientific directions.

Manchester.—The Electric Lighting Committee of the Manchester Corporation have been making full enquiries into the different methods of the electric lighting supply of London and elsewhere, and are preparing an exhaustive report upon the subject, to be presented at an early date to the Manchester City Council. In the meantime they are receiving valuable information from the various electric lighting engineers and supply companies in the kingdom, which will be of great service to them in connection with their investigations.

Lighting Railway Lines.—The Pennsylvania Railroad Company have decided to light the seven miles of their track through Frankford and some neighbouring towns by electricity, so as to lessen the chance of accidents caused by the busy traffic and large number of crossings. Arc lamps will be used, and it is hoped to render the track by night as safe as it is by day. Their example might well be followed, thinks the *Globe*, on some of our London lines, especially those connecting termini on the south side of the river.

Aerial Navigation.—M. Gaston Trouvé has an article in *L'Electricien* (No. 8 and 9, new series), on aerial navigation, by means of an apparatus constructed like a bird, which he maintains is the first ever constructed which. being heavier than the air, yet flies. He poses the data of 7¾lb. per horse-power to be the weight of the apparatus, and discusses the use of electric motors, but seems to prefer cartridges formed of compressed hydrogen and oxygen, which should drive a motor by means of explosions, or a set of double reservoirs actuating an extremely strong and forcible but light motor.

Leeds.—At the meeting on Wednesday, Ald. Firth, the chairman of the Highways Committee, in reply to a question, said that he held in his hand an authority from the Board of Trade to proceed with the work of the Roundhay-road tramways. The only variation from the application which the Corporation had made was that the electrical engineer to the Board required that the cars should be worked at 300 volts instead of 500 volts. The committee had communicated with the Thomson-Houston Company to ask if they were prepared to work the line at 300 volts, and he had received a telegram to say that they were.

Experimental Lighting for Bombay.—"We see," says a Bombay paper, "that the Municipal Commissioner of Bombay is advertising in America for tenders for experimental electric lighting. This is a sign of progress that must be very gratifying to patriotic citizens; but we fear that the effect of the move will be rather spoiled by those captious people, living in Sion, Matoonga, and obscure suburbs of the town, who are complaining that they usually have no lights at all in their streets—not even the humble oil-butty." We think also that the effect of the move, if truly described, will not be relished by English electrical contractors.

Monopoly of Lighting at Luxembourg.—It will be remembered that at Luxembourg a dispute arose some time ago between the gas and the electric companies. The Municipality authorised the electric light company to break up roads in order to lay cables. The gas company then brought an action against the town authorities, maintaining it had a monopoly of public and private illumination, and that the concession to the electric company was a breach of the agreement. The suit was determined against the gas company on the ground that monopoly only referred to gas lighting. The gas company appealed, and the decision has just been confirmed. The electrical company will now be allowed to proceed.

Birkenhead.—A sub-committee of the Watch Committee of the borough of Birkenhead have had under consideration the better lighting of the borough, and have come to the conclusion that the borough is badly and insufficiently lighted. They recommend that the central and principal streets should be better lighted by alterations being made in the existing lamps, and the erection of 120 new lamps in various parts of the borough. The estimated annual cost of the additional lighting of new lamps is put down at £776. 10s., and the probable alterations are estimated at £755. These recommendations, the sub-committee state, are only an instalment of the improvements they think should be carried out.

Electricity in Mining.—The employment of electricity for mining purposes is rapidly becoming a most important industry in this country. England being the largest coal-producing country, efficient means for colliery purposes are likely to be adopted here in ever increasing quantity. We notice many new firms taking up this branch of electrical engineering, and lately an important indication is given in special electrical supplements issued by the *Iron and Coal Trades' Review*. These contain a series of articles specially contributed on "The Dangers of Electricity in Mines," Bolton's article on "Electric Cranes," Pope on "Electric Railways," and various notes of the use of electricity in collieries.

Street Railway Review.—While we are pottering along with one or two street electric railways (we reserve credit for the subways) the Americans are still forging ahead with unexampled rapidity. One of the best indications of this is the appearance of another new journal hailing from Chicago (334, Dearborn-street) entitled the *Street Railway Review*, the first number of which is before us—a large thick journal of 100 pages, beautifully printed and got up generally as is their wont, and containing articles on noiseless motors, Wenstrom's electric works, large electric cars, electricity in snowstorms, electric railways of North America, besides a description, entitled "In Deepest London," of our own success in electric traction—the Southwark Subway.

Matlock Bath.—A report has been received from the engineer appointed to make investigations with regard to the lighting of Matlock Bath Local Board district with electricity. At the monthly meeting of the authority on Tuesday night it was stated 225 promises for accepting lights for private consumption had been received at £1 each per year. The cost was estimated at £1,300 to £2,500, according to the requirements. Mr. F. C. Arkwright, who has the right of the water, had not been seen, but it was not anticipated there would be any difficulty in that direction. The Board will have a special meeting on the business to decide whether to take up the proposal on behalf of the ratepayers or get a company to float the concern.

Preston.—The central station of the National Electric Supply Company at Preston, which has been in course of erection for some weeks past, has now got to work. Two engines, respectively of 120 h.p. and 40 h.p., drives four Blakey, Emmott, and Co.'s dynamos, capable of supplying each 1,800 16-c.p. lamps. Large square posts are set up in the streets (temporarily, only, it is understood), each with a globe containing three lamps each, for public lighting free of charge. There are already 500 lamps running on two distinct circuits, and are supplied from dusk to midnight at £1 per lamp per year, including connections and fittings. The Theatre Royal and Lipton's store have arc lamps. Dr. Aron's meter is intended to be introduced shortly.

Telephone Rates.—A correspondent writing to the *Glasgow Herald* with reference to the proposed Mutual Telephone Company wants to know if the numbers of the new company will be the same as the old, having had two years' stock of stationery printed with their number on it. Since he paid his year's rent, of which there are seven months yet to go, the National Telephone Company have intimated a reduction in the rate, but he wonders whether the difference has been refunded to those subcribers who have paid the old rates for the current year, or whether it is their intention to do so. It will lead to great confusion to have two separate companies, and seeing the National Company took advantage of the monopoly and kept up the rates as they did, it is maintained that the Mutual Company ought to get the entire support of the public.

Electric Alarm.—Mr. John Bellamy, engineer, of Bing-street, Millwall, has reason to see the utility of electric burglar alarms. Owing to his premises having been broken into no fewer than five times during the last 14 months they were fitted with electric alarms, which communicated with the bedroom of Thomas Turner, an employé who resided in the next house. About one o'clock in the morning of Saturday week Turner was awakened by hearing the electric alarm ring. He got up and speedily went for assistance. On the arrival of the police the office door was opened, and two men were found concealed beneath a desk. A third man was also seen, but he succeeded in making good his escape. Both prisoners were committed for trial.

Rome.—The work of installation of the electric tramway to connect the Place del Popolo and the Ponte Mollo, at Rome, are complete, and the line of about the length of 1½ miles has been started. The *concessionaire* is M. Cattori, who placed the work in the hands of Messrs. Foote and Von Buch. Two 60-h.p. engines drive two Statter series dynamos, giving 52 amperes at 850 volts, one set being for reserve. The overhead line of four silicious bronze wires is carried 22ft. above the ground. There are three cars, each carrying a 15-h.p. series motor, and regulation is obtained by a shunt resistance. The line is run in sections in series, automatically worked by the passing cars. The introduction of the resistance of ·1 ohm in the motor circuit is sufficient to reduce the power of the motor to 4 h.p.

Destruction of the Japanese Parliament.—Details are forwarded to the cable agencies of the fire at Tokio which resulted in the complete demolition of the newly-completed Houses of Parliament. They were built of wood, and cost 800,000 yen. The origin of the fire was at first attributed to the soshi, a political class who seek by violence to carry out their views. A closer examination, however, is said to have revealed the fact that the fire originated in the electric wires, although the actual cause of the defect has not been ascertained. The disaster so startled the Emperor that he immediately gave orders to have all the electric lamps removed from his palace, but subsequently countermanded these orders and engaged a private staff of electricians, giving them instructions to lay down an electric motor for the sole use of the palace.

Electricity at Ambleside.—At the special meeting of the Ambleside Local Board to consider the taking over of the gas and water company, a letter from Colonel G. Rhodes was read, strongly urging the Council to let it alone, for the interest both of the shareholders and the Council. "The electric light," he goes on to say, "will eventually be established for Ambleside and district, and electric launches are to be placed on Lake Windermere. Electric 'busses will follow, and then a 20 to 30 minutes' drive from Windermere to Ambleside at a 6d. fare will be the result. The electric cars will supplant our four-horse coaches, same as the steam-engine railways have already done. Establish electric lighting, and the gas company will equally benefit, and more gas will be consumed." A committee was eventually formed to consider the purchase.

Anglo-German Cables.—The intolerable disturbances of the system of telegraphic communications between England and Germany, which occur even in comparatively fair weather, are now, says the *Standard*, to be radically dealt with. There are only two cables between Emden and Lowestoft, and it is to this cause that most of the trouble is due. The Governments of the two countries have at length considered the constant complaints on the subject, and have agreed to lay a third cable. Each Government is to bear half the cost, which will amount in all to about £120,000. A Bill on the subject will soon be laid before the Reichstag, and the operations for laying the cable will commence immediately upon the money being granted. A new cable will also be laid to Heligoland from the Island of Wangeroge, which is already connected by cable with Wilhelmshaven.

Hamstead Colliery.—The Hamstead Colliery Company, of Great Barr, near Birmingham, has been lighted by electric light. The plant, which is contained in a separate building on the surface, comprises a Willans engine and a Hookham dynamo, having an output of 10 amperes at 500 volts pressure. The installation is equal to 50 lamps of 16 c.p. Steam is supplied to the engine from a set of boilers used for furnishing steam to all the surface engines. By means of overhead conductors, the current passes to two circuits, one being taken down the shaft. The main roads, office, stables, and bottom decks are lighted, but no lamps are installed in the workings. At night time the two circuits are run for lighting the engine-rooms above ground and pitheads as well as below. The installation, which has been carried out by Messrs. Chamberlain and Hookham, has been in successful operation for some time.

Meteorological Exhibition.—The Royal Meteorological Society's twelfth annual exhibition of instruments was opened last Tuesday evening in the rooms of the Institution of Civil Engineers. The exhibition this year is devoted to rain and evaporation gauges, and such new instruments as have been constructed since the last exhibition. Almost every known pattern of rain gauge that has been used in this country is shown, and some interesting storm gauges and self-recording gauges are also exhibited. The evaporation gauges include several instruments employed for measuring the evaporation from a free surface of water, and others for use with growing plants. A number of new instruments are also exhibited, among which are various anemometers, recording barometers, and cameras for meteorological photography. The exhibition will remain open till Thursday, 19th inst.

Electrical Drills.—The audience at the Society of Arts on Monday were much interested in seeing Mr. Kapp manipulate the electric drills and cutters and borers. The electrical drill embodies the important application, invented by Mr. Rowan in 1882, of the use of strong electromagnets to hold the drill in its place—on the ship or boiler side, or wherever it may be required. This sucker action is turned on before the drill itself acts. The efficiency of the drills in actual work was stated to be 66 per cent. We notice that in a contemporary Mr. W. H. Willatt, replying to Mr. Rowan in relation to the invention of these drills, while acknowledging the master patent for the use of magnets for holding, repudiates any suggestion that Mr. Rowan must design every form of electrical drill until the expiration of that patent, and mentions that in the spring of last year he designed a special electrical drilling machine for the Earle's Steamship and Engineering Company to bore 2⅜in. hole in a sloping deck.

Consulting Engineering.—The *Freeman's Journal*, in a leading article, alludes to our recent action upon the needed reform in consulting engineering practice, and after quotation from our article, draws the attention of the Dublin authorities to the matter in the following words: "The sum and substance of these general remarks may be briefly stated. Consulting engineers, it is contended, should draw up plans and specifications to guide contractors, and not merely issue a few guiding clauses, leaving the contractors to make their own specifications. Naturally the *Electrical Engineer* writes from the electrician's point of view, but it is certainly open to argument whether the system of adopting fixed specifications and plans would be workable in practice, and it obviously would not be so favourable to public bodies. At the same time we are far from denying that an able engineer who sends in a tender, and finds his ideas appropriated without any reward, has a legitimate ground of complaint."

Electric Lights for Lightships.—The American Lighthouse Board is considering the feasibility and advisability of placing electric light beacons upon several of the new lightships to be stationed along the Atlantic coast, which are now in course of construction or under contract. It is stated that it was originally intended to equip these vessels with the best modern lights which could be obtained and the lenses and lamps to be of the highest order. It is thought possible, however, to obtain a better light by the use of electricity, in which case it would be desirable to equip the new lightship which is to be placed at Sandy Hook, and one or two others, with the electric light. In order to ascertain if the benefits which an electric beacon may possess over the regulation lamps will justify the additional expense, the Lighthouse Board will undertake a series of experiments to be conducted at the lighthouse station on Staten Island. It is also proposed to equip two or three of the new lightships with flash lights, to be produced by means of revolving shades. The system of electric lights now in use on the buoys in Gedney's Channel, in New York Bay, are reported to give perfect satisfaction.

Telephone Subways.—The London County Council have had before them an application from the Universal Telephone Company for permission to run two wires, twisted together, in the subway of Northumberland-avenue, for the purpose of establishing communication between the Hotel Metropole and the Grand Hotel. There appears to be no objection to this proposal; but the Highways Committee are of opinion that the company should be called upon to pay a small rent for the use of the subway for the purposes of its business. They therefore recommend that the Universal Telephone Company be allowed, during the pleasure of the Council, to run their two wires upon condition that the positions in which the wires shall be placed in the subway shall be determined by the Council's chief engineer; that the space occupied by them shall not exceed that which would be taken up by a 2in. pipe; that the work of placing them shall be carried out, and that any damage that may be done to the subway in the execution of the work shall be made good, to the satisfaction of the Council's chief engineer, and at the cost of the company; and that the company do agree to pay a rent of £1 a year in respect of the use of the subway during the time that the wires remain there.

Telegraphs to Lighthouses.—The subject of telegraphic communication with lighthouses, lightships, and lifeboat stations was discussed at the meeting of the Associated Chambers of Commerce on Wednesday, on the resolution of the Cardiff Chamber, seconded by the Plymouth delegate, who proposed that these places should be placed in telegraphic communication with the general telegraphic system. The motion was supported by Sir C. Palmer, M.P., Sir H. Waring, and others; and Sir Michael Hicks-Beach, M.P., in speaking upon it, said he hoped the Chambers, if they came before him upon this subject, which, so far as it affected the saving of life, could not be overrated in its importance, would be prepared to say from what fund the costs should be paid of making the suggested communications, for if the costs should fall upon the Commercial Marine Fund, there would be an increase of the light dues, and he had not gathered from the discussion that the Chambers were in favour of this increase. The president, speaking on behalf of the shipping interest, said that if the telegraph communications between lighthouses and the land would save life the increase of the light dues would be cheerfully borne, and he hoped the matter would be taken in hand at once. The resolution was carried.

Low-Tension System for Islington.—The Works Committee of the Islington Vestry reported on February 20 that they had considered the draft provisional order of the Camberwell and Islington Electric Light and Power Supply Company, by which authority is sought to supply electricity in the parish for the purposes of both light and power on the low-tension system. The system proposed to be adopted by the company is entirely different to that of the House-to-House Company, to whose order the Vestry consented last year, the former being on the low-tension system, which enables the company to supply electricity not only for lighting, but also for power and other purposes; while the latter is on the high-tension system, with transformers on the consumer's premises. The committee was of opinion that, subject to certain requirements being complied with, and to a satisfactory understanding being arrived at as regards minor details, the Vestry should give its consent to the order. Mr. Furlong, in moving the adoption of the report of the committee, said that this company had promised to move in the matter as soon as they obtained a provisional order, and it was a fact that they had secured premises near the Vestry Hall, so that now there seemed to be a good chance of the main thoroughfares being lighted by electricity. Mr. Vine, in seconding the adoption of the report, remarked that the company not only proposed to supply electric light, but electric power for various trade purposes. In reply to Mr. Cussans, the vestry clerk said that the wires were to be placed underground. The proposition was carried unanimously.

Chelsea.—The Electric Lighting Committee of the Chelsea Vestry reported that they had considered the letter from Mr. R. Chamberlain, M.P., dated February 3rd, thanking the Vestry for their letter of January 31st, transmitting copy of a letter addressed by the Board of Trade to the Chelsea Electricity Supply Company in reply to their application for permission to discontinue the supply of electricity during certain hours of the day; asking the Vestry to take into consideration the question of appointing an inspector under the Electric Lighting Acts, and suggesting that the duties might be performed by one of the existing officers. The committee have ascertained that the number of houses supplied, or about to be supplied, by electricity in the parish is as follows: Chelsea Electricity Supply Company, Limited, 215; Cadogan Electric Light Company, Limited, 16; London Electric Supply Corporation, Limited, 2; but are unable to make a recommendation in the sense indicated by Mr. Chamberlain. The committee also reported that they had considered the letter from the Cadogan Electric Light Company, Limited, dated February 4, stating that they are at the present time working under an agreement with the Vestry; and being about to transfer their business to a newly-formed company—viz., the New Cadogan and Belgrave Electric Supply Company, Limited—they beg respectfully to ask if the Vestry will consent to the transfer of the said agreement to the new company, who will be bound by the conditions therein stipulated. On this the committee recommended "that the Cadogan Electric Light Company, Limited, be informed that the Vestry prefer that the company should obtain a provisional order authorising them to supply electricity in the usual manner." These reports were approved, and the recommendation adopted.

Lecture at Glasgow.—Before the Institution of Engineers and Shipbuilders at Glasgow, last week, Mr. Henry A. Mavor read a paper on "The Development of Electrical Distribution." The problem of the economic distribution of electricity, he said, was daily becoming of greater importance as it application to various industrial and domestic purposes extended. The enormous rapidity with which its extension was taking place created the problem, and the solution of it was an immediate necessity. The most prominent application was, of course, to electric lighting; but it was a curious fact that theoretically this was one of the least promising of its applications. The public recognition of the value of electricity as a light-producer probably arose from its possibilities in this direction having been first developed. Mr. Mavor then proceeded to describe the methods of distributing electric energy, showing how complicated arrangements for the public service had grown out of the simplest original systems. He described the manner in which conductors were laid underground and overhead, and the arrangements for the utilisation of the currents from these conductors for the purpose of the electric traction of street railways. In closing, he pointed out the immense value of such a method of transmitting power, exhibiting a 2in. iron pipe, which contained conductors on the Brooks system, for the transmission of 1,500 h.p. over 12 miles, with a loss of only 2 per cent. Lantern illustrations were shown of the plan adopted in America for overcoming the difficulty of placing conductors underground, and an explanation was given of some of the applications of stored electricity to locomotion. The discussion on the paper was adjourned till next meeting.

Central London Railway.—The Bill for the Central London Railway came before a committee of the House of Commons on Tuesday. Mr. Pember, Q.C., in opening the case for the promoters, said that the proposed line of this year was six miles long, as against 4½ miles last year, and that it was intended to run 50ft. underground from Shepherd's Bush to Cornhill. The shield process of excavation would be used. The total capital of the company was £2,700,000 in shares and £900,000 borrowing powers, the railway to be completed in five years. The motive power was to be electricity. The vibration of the railway would be not heard on the surface, and the trains would make their own ventilation. The maximum speed was to be 25 miles an hour, or 15 miles an hour including stoppages, 25 per cent. quicker than the Inner Circle trains. A passenger would be able to get from the Marble Arch to the Bank in a quarter of an hour. The company did not seek power to break up the streets, and clauses would be inserted for the protection of the sewers and gas and water-pipes. He also pointed out the necessity for some further means by which the present congested state of the traffic in the streets of the metropolis could be alleviated. As an instance where a line of this kind had been worked with success by electricity, he might mention the Manhattan Railway, which in 1889 carried 179,000,000 passengers over a mileage of 32 miles, the gross earnings being £56,000 a mile. He alluded to the success of the City line. On the proposed line the tunnels would be larger, the stations more commodious, and the service quicker, and running on every day of the week. Mr. Greathead, engineer to the line, then gave evidence. On Wednesday, Sir Benj. Baker, Dr. Hopkinson, on technical, and Mr. Hamilton Smith on financial matters, were examined. The opposition evidence will next be taken.

THE POST OFFICE INSTALLATION.

(*Concluded from page* 186.)

It may be well to give some mention of the feed-water heater used in this installation. This is Atkinson's patent, made by the British Gas Engine Company, Gospel Oak. The use of the heat from the exhaust steam to warm up the water before going into the boiler, is combined with entire freedom from back pressure, accommodation for unequal expansion, purification of the water, and facility for cleaning out or examination. The feed-water heater is shown in elevation and section in the accompanying illustrations, Fig. 12. The exhaust steam from the engine enters at the pipe marked "steam inlet," and passes away in a direct unimpeded course through a channel of similar sectional area throughout to the "steam outlet," from which the exhaust pipe conducts the steam not utilised in heating the water away in the usual manner. This channel is, however, open at the top to the tube plate, into which are screwed the ends of a number of vertical tubes, open to the exhaust steam below but closed at their upper ends, which are thus left to expand or contract without straining. In each of these heating tubes is a small circulating tube leading from near their upper ends to the channel, through which the exhaust steam passes at a speed of nearly a mile a minute. The mouths of these tubes are bent, as shown, in the direction of the exhaust steam, so that the steam in passing causes a strong induced current out of them, rapidly removing the air they first contain when commencing to work, and causing the very slight amount of expansion required to create an up current and fill them with steam. The heating tubes are thus filled with exhaust steam at a constant temperature of 212deg. F., and as the space around them is filled with water, they rapidly transmit the heat of the steam to this water, automatically drawing up as much steam as they require. The remaining steam not only passes unchecked, but by being reduced in volume from one-third to one-half, it passes through the remaining length of the exhaust pipe with less resistance than at first, and the engine thus actually works with less back pressure than if the feed-water heater were not attached.

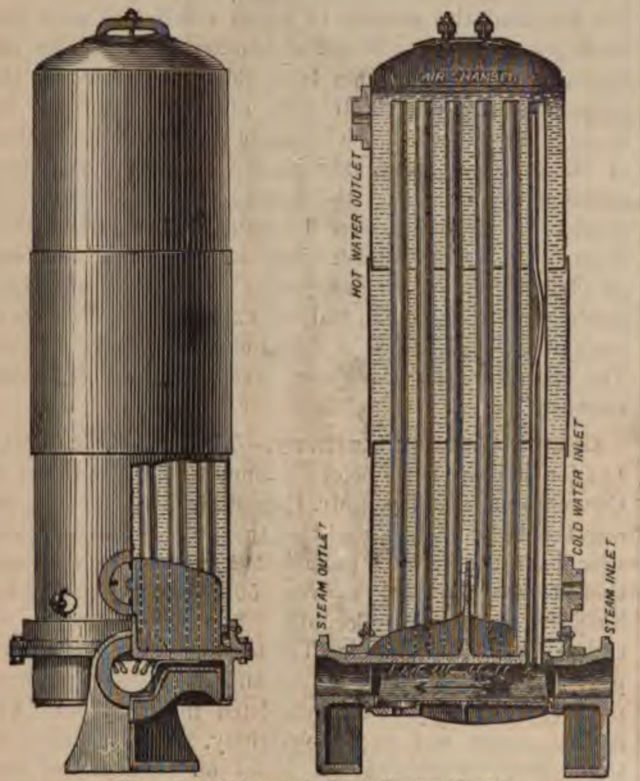

FIG. 12.—Atkinson's Feed Water Heater.

The cold water is pumped into the lower part of the water-cylinder at the point marked "cold water inlet," when it is rapidly heated to a boiling temperature, passing to the top, and the same action forces the boiling water into the boilers. The water-cylinder is large enough for the same to spend some time in passing through and thus deposit any impurities; the lower part of the cylinder is divided by a partition, which prevents the disturbing influence of the entering cold water from affecting the hot water on the other side, thus allowing the impurities to settle there as soft mud. A blow-out cock is provided for occasionally removing this mud.

With the use of this apparatus one-fifth of the total work in making steam is done by the heater, and the remaining four-fifths is carried on with greater relative economy, as the loss of water from priming passing, leaky cocks, etc., is obviated by the use of boiling feed-water. The total saving from these causes will vary, but it is guaranteed by the makers to exceed 20 per cent., and is stated to be frequently as much as 25 per cent. Four boilers and one heater will therefore do as much work as five boilers of the same size without the heater, which costs far less than a boiler, besides the saving in fuel and to the boilers by the prevention of local strains from cold water. By preventing the actual contact of the exhaust steam with the water heated, no grease can get into the boiler. The absence of back pressure is a more important point than might at first appear. With water-heaters that receive the steam into a chamber the momentum is lost, and it must again start and be forced through the tubes by the energy of the steam from the engine, and back pressure on the engine must result. Taking a back pressure of only 1lb.—a moderate estimate, as it is not unfrequently 3lb. and upwards—with a boiler pressure of 45lb., the mean pressure on the piston would be about 25lb., out of which 1lb., or 4 per cent. of the available power of the engine, is lost in forcing the exhaust steam through the heater. But with the ingenious arrangement adopted, the back pressure is even less than with an open pipe.

Having indicated the boiler arrangements, we will return to the dynamos and their circuits.

Under the floor of the dynamo-room a sloping brickwork culvert has been built to receive the cables leading from the dynamos to the main switchboard. When building, the culvert has had iron hooks fixed therein at proper intervals to carry the cables. In laying the cables, each cable has had strung upon it a number of brown earthenware insulators. These are slipped along to their right distance along the cables, and are then placed upon the iron hooks, thus serving as simple means of insulating and carrying the conductors in the culvert. The culvert is sloped both to allow for the varying numbers of the cables, and also to allow any moisture that may happen to get into it to drain away.

The installation is wired in two distinct circuits throughout. In usual working, dynamos 1, 3, 5 are to be run in parallel on circuit 1, and dynamos 2, 4, 6 on circuit 2. The cables from the dynamos are taken first to the main switchboard in the engine-room, and from thence to the various floors, each floor having its own distributing switchboard, and thence to the lamps, each lamp having its own switch.

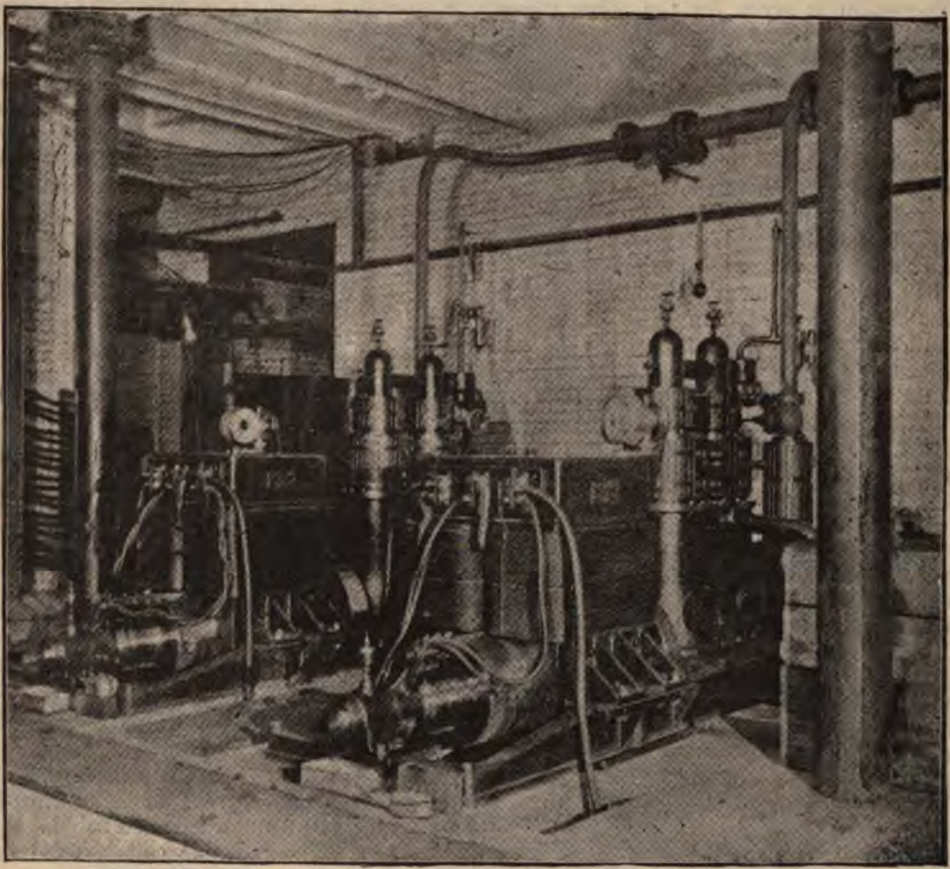
The dynamo switchboard is constructed with two rows of switches, the first row for the positives, the second row for the negatives. The switches are of a peculiar and special construction, already shown in Fig. 1 previously given. There are six of these switches in each row, one for each dynamo, and each switch is constructed to feed on to eight distinct circuits as desired. As will be seen on turning back to refer to the illustration, the switch has eight handles standing out; by moving the handle, the detail of which is shown above (Fig. 1, p. 136, Feb. 6), connection is made across from the circuit desired to the central block, which is connected, as the case may be, to the positive or the negative pole of one of the dynamos.

The total of 12 eight-way switches are mounted upon one large switchboard at the end of the dynamo-room. The connections are, as shown in Fig. 5 (p. 158, Feb. 13), made by solid copper strips at the back of the board. The round dots represent the terminals of the switch, the cable from the dynamo being led in each case to the centre contact, and connection is then made across as required by moving the switch handle. It is thus easily seen that any dynamo may be switched on to any circuit by moving the handles belonging to this circuit upon the positive and negative switch under the number of the dynamo required.

The dynamos are numbered 1 to 6, and each is furnished with a Dolivo ampere-meter for 600 amperes placed above the switches. This switchboard was manufactured to drawing by the General Electric Company, Queen Victoria-street.

On the wall opposite the engine, and in full view of the driver, are placed two large voltmeters, one in each circuit, giving the electric pressure at the dynamo. Upon the other wall are two more voltmeters, to which wires are led from a distant point in the building, thus indicating the working pressure upon the lamps in actual use. The driver has thus under his eye all the information required for perfect regulation of his machinery. Every cable and wire in the building has been calculated for a fall of 2 per cent. in the E.M.F. The unsoldered connections, such as fuse-boxes, will take 1·2 per cent. This allows a little over 1½ per cent. in the engine regulation to afford a working pressure of 105 volts in the lamps.

From the switchboard the cables are led to distributing switchboards situated one upon each floor—basement, ground, first floor, and second floor. The details of the switches for these are shown in Fig. 2, already given (Feb. 6), and the general arrangement of the whole distributing board is shown in Fig. 3 same date, p. 138. The ground floor is divided up into five distinct circuits, named A, B, C, D, and E. The mains from the two principal circuits, named 1 and 2, are led to the main terminals at the bottom of the board—those from No. 1 to terminals 1 – and 1 +; and those from No. 2 to 2 – and 2 +. From here the circuits go through the respective ammeters 1 and 2; and thence are distributed to the distributing switches, A, B, C, D, E. These switches are of special construction to allow any circuit to be connected to No. 1 and No. 2 circuit as desired. It will be seen that each circular switch, Fig. 3, has two inner ring contacts marked + + and – – respectively. The + ring is connected behind the board to the + terminal of a fuse-chamber board (described presently), to which one end of the actual lamp circuit is joined, and the – ring goes to the circuit switch "ON, OFF," and so to the – terminal of the fuse-board, to which the other end of the actual lamp circuit is joined.



One Bay of Dynamo Room, Post Office Installation.

The detail of the circular switch is shown in Fig. 8 (p. 160), where the contact-piece not indicated in the larger figure is seen. This contact-piece connects the upper inner contact to one of the outer contacts, and the other inner contact to the diagonally opposite outer contact—the two switch bar pieces being insulated from each other. Now, by turning the handle of the circular switch, A, to one side, so that the bar connects the ring + to the contact 2, and the ring – to the contact 2, Fig. 3, the corresponding lamp circuit, A, will be thrown on to the dynamo circuit No. 2. By turning the lower triangular switch A to the position "ON" the lamps are then turned on. On the contrary, if the handle of the circular switch is turned in the other direction the contacts are made with circuit No. 1, and this can, of course, be done with any of the branch circuits, A, B, C, D, or E, as required. In this way, by a glance at the ammeters, the amount of current in main circuits 1 and 2 can be seen, and can be regulated by turning the handles to make contact with terminals 1 and 2 of the interchangeable switches, as the case may be.

Below the distributing switchboard is placed the fuse-chamber board, of which a general view (it should be looked at sideways) is given in Fig. 7 (p. 160). The fuses guarding lamp circuits, A, B, C, D, E, on circuit 1 are so marked, all the negatives being to one side, and all the positives to the other. The lamp circuits for circuit No. 2 are lettered *a*, *b*, *c*, *d*, *e*.

The details are shown in Fig. 6 (p. 159). Each fuse-chamber is lined with slate slabs, and has a glass front. The fuse is inserted and fastened by means of the screws. The floor of the fuse-chamber is sloped downwards to allow any melted metal to fall to the back and thus to prevent the glass front from being cracked.

The lamp circuits taken from these points are led in wood casing on the surface of the wall or ceiling along the rooms to be lighted. Each branch from the lamp circuit has its fuse, placed fully in sight and just beyond reach of interference, but easily within reach of an attendant with a short ladder.

Having followed the conductors from the dynamo to the lamps, we now come to the system of distribution in the rooms themselves. The chief consideration in the first place has been the full and sufficient lighting of the great sorting-rooms on the ground floor. These long halls present a very busy appearance when viewed from the little gallery above at about half-past five in the evening, when the mails begin to come in. Long rows of sorting-tables run down the length of the hall, each having in front of it pigeon-holes marked with the names of the centres of London and the principal railway routes, into which the clerks rapidly sort the various bundles. The lighting is obtained by arc lamps, disposed as below.

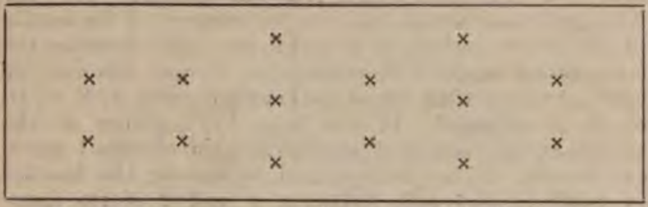


FIG. 13.—Arrangement of Arc Lamps in Sorting-room.

There are thus 14 arc lamps in the first sorting-room, and a similiar disposition is given for the other rooms, making in all 60 arc lamps. Great pains have been taken to obtain the best general illumination to throw a full light on all the tables and racks and avoid all cross shadows, the place of the tables having been all previously set out and the angles of diffusion graphically represented to obtain the best arrangement. The lamps are hung 14ft. from the ground, so that the light is given to the points most required from an angle of 45deg. The lamps are not arranged with sliding pulleys and loose coils of cable, but are fixed at the height named, which can easily be reached by the attendant by means of a light tressel. The lamps are run two in series off the 110-volt circuit and burn most admirably and steadily; the man who is in attendance has watched for the flickering, and has been unable to detect variation for hours together. The sets of two lamps are arranged alternately upon the two different main circuits, so that the accidental failure of one would yet give good general illumination. This principle has been carried throughout, and alternate lamps or groups only are upon the same circuit, the intermediate ones being on the second circuit.

In the circuit of the arc lamps an ingenious electro-magnetic arrangement has been adopted by Mr. Brockie, which sets up a counter E.M.F. directly the arcs are struck, and enables the lamps to burn steadily within a few seconds of switching on, without the irritating "pumping" effect often experienced with arc lamps run in series in the manner here adopted.

The gain in comfort and purity of air has been most marked and noticeable. Late in the night in crowded times, when gas was employed, the atmosphere used to become almost insufferable, and to use a picturesque expression given by the men, "could be cut by a knife." Now the air remains far cooler and comparatively pure, and with the increased energies of their staff of 3,000 men, it is almost as good as an extra 500 men.

The side rooms and upstair rooms on the first and second floor are lighted with 16-c.p. incandescent lamps, each electric light replacing a gas jet. The lamps are placed upon standards, which carry large green shades to reflect the light downwards and protect the eyes, and these are made fixed to prevent interference. The wiring, however, is not carried up the tables, but a cord is dropped down from casing in the ceiling to the fixed standard. This arrangement saves expense in casing, and makes everything visible. Each lamp has its own switch, and the men are required to turn off their lamps when not in use. Besides the more delicate lamp fuses, which are placed in conspicuous positions, but well out of reach of passers-by, there are also at every service branch from the lamp main double-pole main fuses, set to go at 100 per cent. over normal current.

In the registered letter department the experiment has been tried of lighting by 50-c.p. incandescent lamps, arranged in between the tables at longer distances, but the experience of the clerks does not seem to favour this arrangement, and the rooms fitted with 16-c.p. lamps are found to give the best light for sorting purposes.

The whole of the arrangement and installation of this plant has been carried out, under the direction of the chief engineer to the Post Office, Mr. W. H. Preece, F.R.S., by his able assistant, Mr. I. Probert, electric light engineer to the Post Office, who has personally superintended the whole work in connection with the necessary calculations, preparation of the drawings, and the details of the switch-boards and fuses, which have been worked out to special designs to embody the necessary safety and facility of manipulation for such a large and important institution.

The whole of the engineering work has been supplied and carried out by Messrs. Willans and Robinson, the names of the actual makers of boilers and special machinery having been already given. The wires and cables have been supplied by the India Rubber and Telegraph Company, Silvertown; Henley's Telegraph Works Company; and Messrs. Walter T. Glover and Co. The switchboards were made to design by the General Electric Company and the Acme Works. The incandescent lamps, of course, are by the Edison-Swan Company, and the Brockie-Pell arc lamps by Messrs. Johnson and Phillips. The wrought-iron brackets for the outside arc lamps were designed and manufactured by Messrs. Lea, Sons and Co., of Shrewsbury. The whole plant makes a model installation of arc and incandescent electric light, reflecting the highest credit both upon the officials of the Post Office and the numerous firms who have co-operated to carry out the details, and will long remain a standard for the realisation of the best modern conditions of an important electric lighting scheme for concentrated public buildings.

THE FRAGER ELECTRICITY METER.

This meter, which was described some time ago in *La Lumière Electrique*, has since undergone some important alterations, most of which will be seen in the accompanying illustrations.

It has been very favourably received, and the owners have obtained excellent reports of its accuracy from some of our eminent authorities, but being of French origin, it has naturally been employed more universally in France than elsewhere, although a considerable number are in use here.

Although it appears at first sight somewhat complicated, it is really extremely simple and accurate, which is, after all, its chief recommendation. It consists of three parts—viz., a wattmeter, an electrical clock (actuated entirely by the current), and the registering mechanism.

Wattmeter.—The wattmeter is composed of a fixed series circuit made up of two parallel coils, A A′, Figs. 1 and 2, through which the whole current to be measured passes in series with the lamps and a movable bobbin, B, in parallel with the lamps. The movable coil is fixed on a hollow shaft, through which passes the fine wire suspension, F F′, which, being fixed rigidly at both ends, serves, at the same time, the purpose of a torsion spring. When the current passes, this movable coil takes up a position of equilibrium between the force of mutual attraction between itself and the series coil, and the resistance of the torsion spring; this position indicates the energy in the circuit at the time, and the needle, L N, acts as the medium between the wattmeter and the dials, as we shall see.

Electrical Clock.—The electrical clock, which beats seconds, consists of a horizontal pendulum, $j\,l\,h$, Figs. 3 and 4, having a rotary motion, fixed on a vertical axis, m. The movement of the pendulum is started and maintained periodically by a fine wire coil connected to the two terminals, 1 and 2. The spring switch, c, is in the circuit of the bobbin, a. When the pendulum is at rest the tooth, ρ, of the switch takes up its position in the notch in loose washer, e, on the top of axle, and the spring of the switch makes contact at d. When the current is turned on, the soft-iron end, j, of the pendulum is drawn into the centre of the bobbin, and the pin, t, in the top of the axle moves the loose washer, e, and by doing so throws the tooth, ρ, out of the notch, and thereby breaks the circuit; when the current is thus cut off, the pendulum, under the influence of the spiral spring, s, flies back, and just when its other soft-iron extremity, h, arrives at the mouth of the solenoid, the loose washer, *e*, allows the tooth, ρ, to enter the notch again, and contact is re-established, and the pendulm, being attracted in the opposite direction, acquires a further impetus with each simple oscillation. These repeated impulses would develop, if continued, oscillations much too large, but they are checked by the regulating washer, *f*. This washer, *f*, is mounted underneath *e*, but is also loose on the axle of the pendulum, and partakes of its movement by means of a tooth attached at right angles to the plane of *e*, free to move in a keyway in the side of *f*. This washer, *f*, also has a notch for the tooth, ρ, of the switch, but its movement in relation to the washer, *e*, is such that when the oscillations of the pendulum become too great the two notches do not correspond, and consequently the contact remains broken till the amplitude of the oscillation is reduced. When the current is turned off altogether this oscillating movement ceases gradually, and the washers, moving through a smaller arc each successive oscillation, are brought into a position nearly symmetrical with the position of rest of the pendulum, the tooth falls into the middle of both notches, contact is established, and the instru-

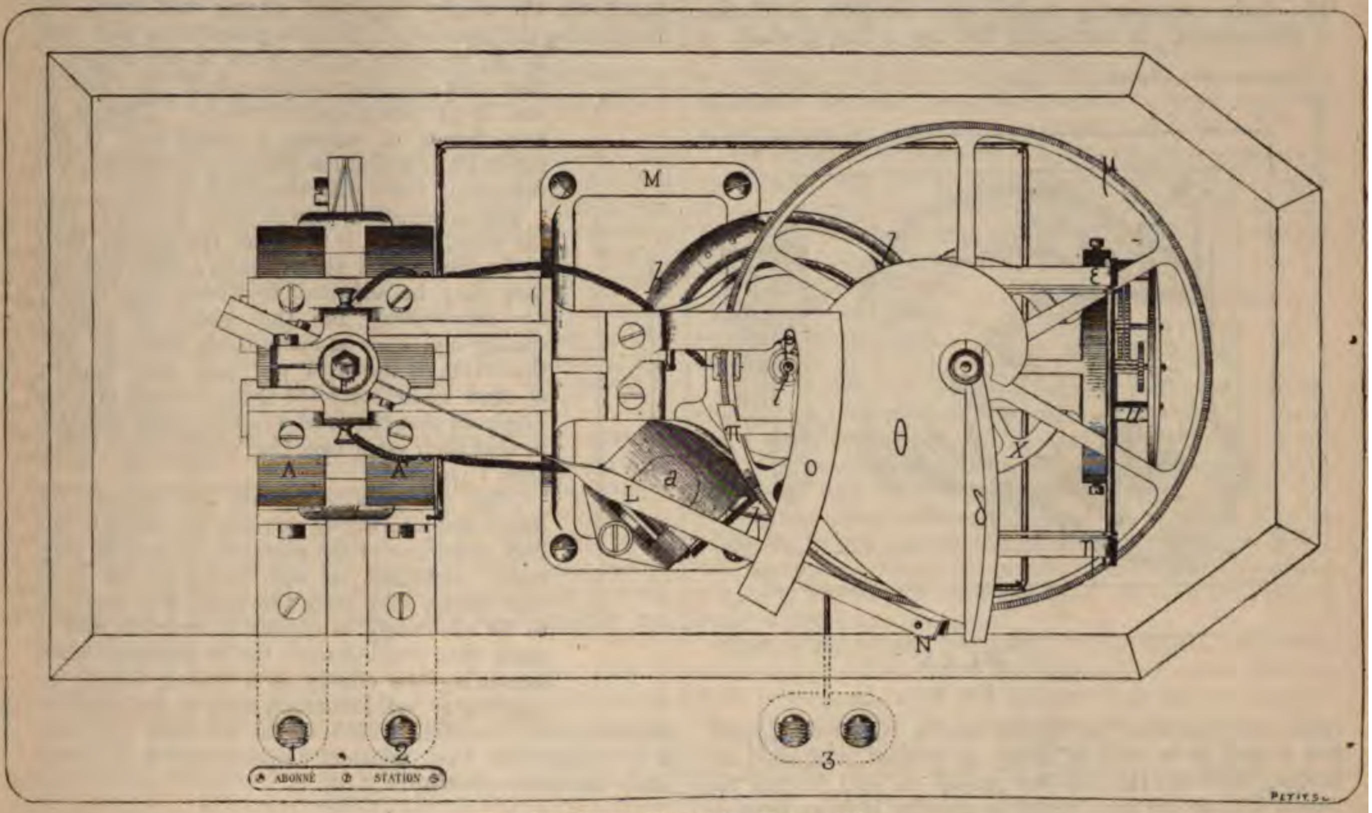

Fig. 1.—Frager Electricity Meter. Plan.

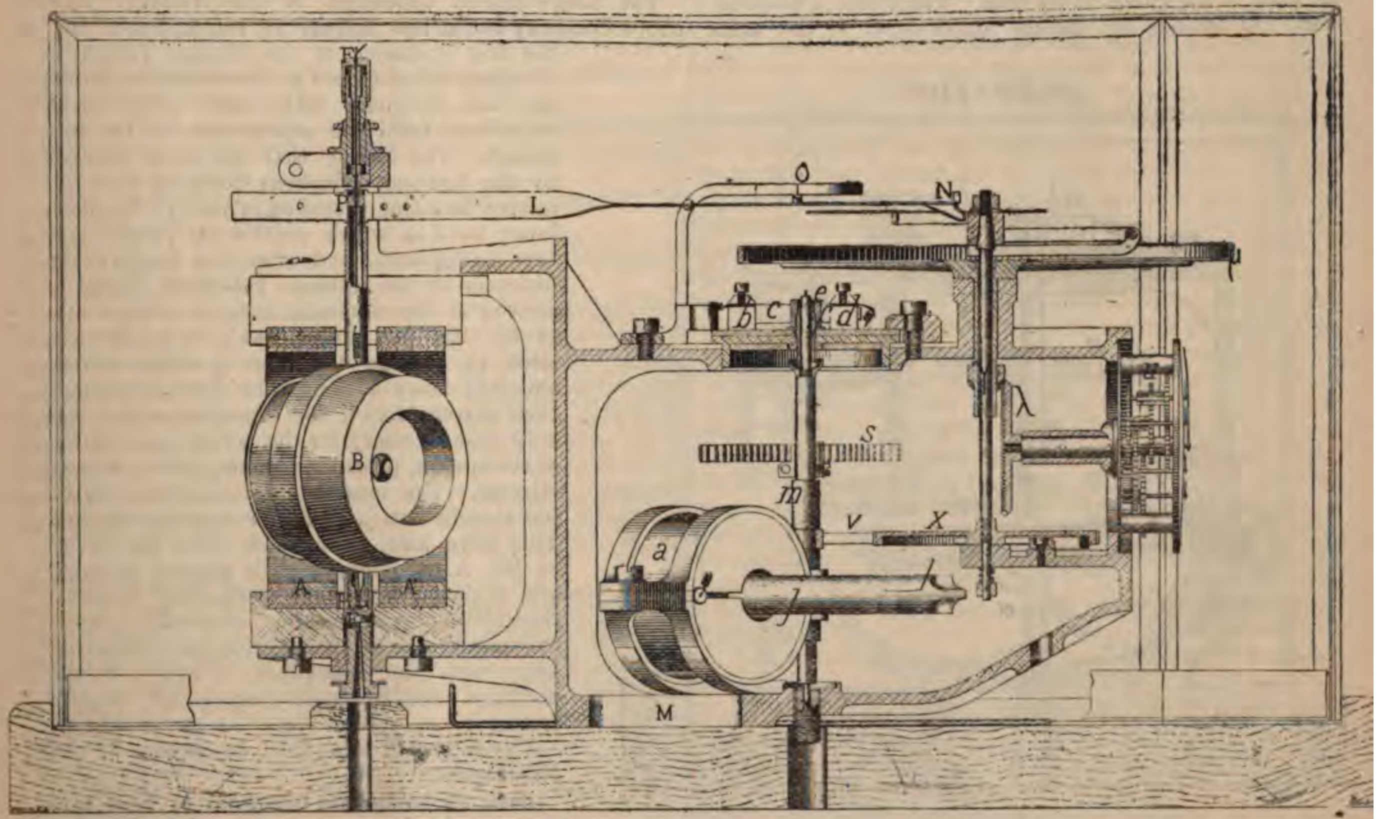

Fig. 2.—Frager Electricity Meter. Elevation.

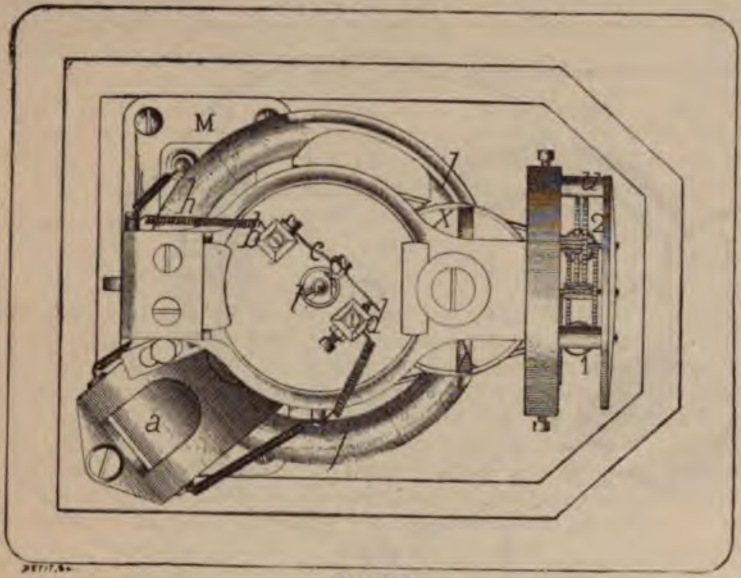
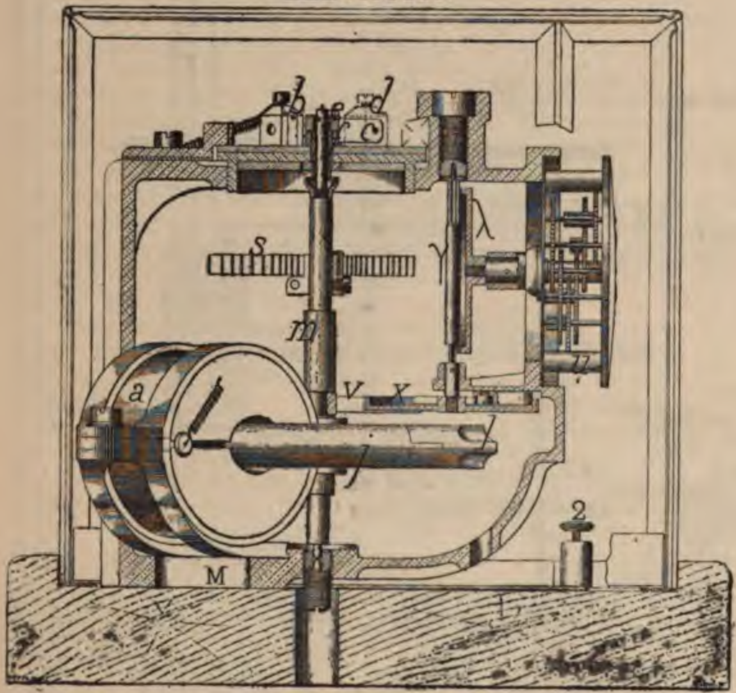
ment is ready to start again. The motor coil is also connected in parallel with the lamps. The motion of this pendulum is communicated to the shaft, γ, by means of the eccentric, *v*, and the wheel of 100 teeth, *x*, which it pushes round one tooth every oscillation; this shaft consequently makes one complete revolution in 100 seconds. It carries at the top a bar, δ, which at each revolution lifts the flexible needle, N, whatever position it may be in, and, in doing so, presses it against the bridge, O; when the bar has passed on and is free the needle falls on the cam, θ, and in pressing it down from its horizontal axle, εη, the tooth, π, engages in the wheel of 600 teeth, μ, and continues to do so until the cam has travelled so far that the needle leaves it. The outline of this cam is such that for any position of the needle the angle through which the wheel, μ, moves is proportional to the watts in the circuit at the time. The wheel, μ, advances every 100 seconds an amount proportional to the watts indicated by the position of the needle at the instant when it is caught by the bar, δ. These individual impulses are added up, as it were, and communicated to the dials, through a train of clockwork suitable to the units chosen, by means of the bevel wheel, λ, and thus the increase in the readings on the dials in a given time denotes the energy expended in the circuit during that time. A large needle is fixed on the dial, which advances every 100 seconds a certain number of divisions. These divisions indicate in watt-hours the energy expended during that time. By multiplying the number of divisions passed over each time by 36, we arrive at the watts in the circuit, so that each division corresponds to 36 watts, or one 10-c.p. lamp approximately. This is an easy means of making a rough test of the meter by counting the lamps so registered, and comparing them with the lamps in use.



PLAN

Fig. 3.



ELEVATION

Fig 4.

The principal feature in these meters is that the error, if any, is the same throughout their entire range, and consequently, after one test they may be adjusted to within $\frac{1}{100}$ merely by substituting for the wheel, λ, another similar one with as many teeth, more or less, than 100, as the error per cent. may require, so that when corrected their accuracy is absolutely all that the most exacting could demand, in that their error over the whole range is less than 1 per cent.

They are equally suitable and accurate for direct and alternating currents, as, owing to the high resistance of the movable coil and its very small coefficient of self-induction, the error that might arise from this cause is so small as to be absolutely negligible in practice, and is more than overbalanced by its accuracy when measuring the energy in a circuit, having an appreciable self-induction, such as arc lamps or retarding coils, because, in such a case, the error per cent. in an instrument that registers amperes only is an absolutely unknown quantity.

THE MANCHESTER MUTUAL TELEPHONE COMPANY.

The long-expected opposition to the National Telephone Company has at last become an accomplished fact, the first exchange of the Mutual Telephone Company being opened in Manchester on Saturday last, February 28th, with results which more than fulfil the expectations of the promoters. The feeling that the rates charged by the National Telephone Company were excessive has long prevailed in view of the much lower tariff to which continental people have been accustomed, and after due enquiry the directors of the Mutual Telephone Company arrived at the conclusion that an average rate of £5. 10s. per annum would be amply sufficient to provide the best possible service, and still leave a profit to be divided amongst their shareholders if the capital expended was only that necessary for the actual construction of the system, promotion money being strictly tabooed. The rate they decided upon was £5 for shareholders and £6 for non-shareholders. They have also determined, under the advice of Mr. A. R. Bennett, their general manager and engineer, to prevent overhearing conversations by employing nothing but metallic circuits in connection with their exchanges; and to do away with the annoyance of delay at the exchange and through ringing off, Mann's system is employed.

The following is a brief description of the Mann system:

Each subscriber has two wires or lines connected to his instrument. One of these (called the Main Line) is for conversing with other subscribers only. The second (called the Signal Line) is for communicating with the operator only.

The signal line is brought into use by depressing (and keeping steadily down as long as required) the small lever which projects on the right-hand side of the instrument.

So long as this lever is pressed down the subscriber's instrument is in circuit with the signal line, and cut off from his main line. When the lever is allowed to rise by the finger being taken off it, the instrument is in circuit with the main line, and cut off from the signal line.

At the exchange, operators are continually listening on the signal lines; therefore no ringing is required to call their attention.

One signal line is allowed to about 60 subscribers. As a consequence, when two subscribers on one signal line chance, as will frequently happen, to depress their levers at the same moment for the purpose of giving instructions to the operator, they will hear each other's voices. But, as the signal line is reserved entirely for giving instructions to the operator, this does not imply that conversations between subscribers (which take place exclusively on the main lines) can be overheard. On the contrary, the greatest merit of the mutual system lies in the fact that conversations cannot be overhead.

The instructions to the operator consist of two or three words (see below) which occupy only about a second to deliver. Therefore if, on depressing his lever, the subscriber finds another already giving instructions, he has no appreciable time to wait. In such a case he keeps the lever depressed, and on hearing the operator acknowledge receipt of the passing instructions he can immediately add his own. Subscribers soon learn to follow each other rapidly and without interference.

The working of the system is so expeditious that an operator can receive, acknowledge, and execute instructions as fast as the subscribers can speak them. Nothing but the giving of bare and necessary messages is permitted on the signal wire, and operators are forbidden to enter into any conversation. Should a subscriber have anything beyond the usual instructions to communicate to the exchange, he must ask to be connected to the chief operator, who will speak to him on his main line. A feature of the system is that a subscriber can tell by means of his bell that his instructions have been carried out. When his main line is not connected to another subscriber's, his bell will not ring when he turns the crank. The moment his bell rings in response to the turning of the crank he knows that the connection asked for has been made, and that his correspondent's is also ringing.

Conversely, he knows when he has been disconnected from another subscriber, for then his bell will not ring when the crank is turned.

The instructions issued at Manchester for working instruments are as below:

"In giving instructions use numbers only. Operators are strictly forbidden to accept names.

"To call another subscriber, take the receiver off the fork and place it to your ear. With your finger depress the signal lever (projecting from the right-hand side of the instrument), and keeping the lever firmly depressed, as distinctly as possible, call out first your own number, and then that of the subscriber you want with the word, 'On' between. Thus, if your own number is 400 and you want No. 60, you say, '400 on 60.' On hearing the operator say 'Right 400,' you remove your finger from the signal lever, thus allowing it to rise; hang the receiver on the fork and turn your crank.

"The moment your bell rings it is a sign that the connection has been made. Give your crank three or four brisk turns after your bell has commenced to ring, then take the receiver off the fork, place it to your ear, and wait for your correspondent's answer, which, if he is attentive, should come immediately. Tell him your name; ask (to prevent mistakes) 'Who are you?' and then proceed with your conversation. When finished, depress the signal lever again, and giving your number, say 'Off'—thus, 400 off.'

"When, after concluding a conversation, say with No. 60, and another connection is required at once, say with No. 730, depress the lever, and call out '400 off,' and then immediately '400 on 730.'

"*To Answer a Call.*—When your bell rings, take the receiver off the fork and enquire 'Who is there?' When finished, depress the signal lever, and, giving your number, say 'Off'—thus '400 off.'

"*Remarks.*—When calling another subscriber, if your first ring does not produce an answer, you must hang up your receiver and ring again.

"It is necessary to remember that the receiver must be on the fork when you ring. When it is off the fork you can neither ring nor be rung. It is also necessary to remember that the signal lever must be kept firmly depressed when speaking to the operator.

"In the event of a connection not being got promptly, you can always call the operator by depressing your signal lever. In doing so you must always mention your number. The operator has no other means of identifying you from any of the other subscribers on your signal line.

"The number of each subscriber's telephone is posted on the instrument thus:

MUTUAL TELEPHONE
NO...................
MANCHESTER.

"Both caller and called should be sure to depress the signal lever and call out his number and 'Off,' after finishing a conversation. If this is not done the operator will leave the two lines connected, and a third subscriber asking for either may be told that he is engaged. When you depress the signal lever and speak to the operator, it is not necessary to call out 'Hello,' or enquire, 'Are you there.' The operator is always there and listening, and you have simply to depress the lever and speak through your instrument without any preamble."

Such is the system given effect to in Manchester. The transmitter employed with the present instrument is of the Bell, or magneto, type, and the best that can be supplied until the expiry of the Edison transmitter patent on July 30. The establishment of an efficient exchange prior to the expiry of the Edison patent in July was more than doubted by many. The National Telephone Company's directors especially scouted the idea, but this opinion was based on want of knowledge of the capabilities of the Bell telephone, when constructed specially to act as a transmitter. The German Government, as is, perhaps, not sufficiently well known, employed nothing but magneto transmitters on their exchanges for nearly eight years, microphones only being fitted in 1887. The instruments employed by the German Government were manufactured by Messrs. Siemens Bros. and Co., Limited, and the same firm was commissioned by the Mutual Telephone Company to manufacture transmitters specially for them. The result at the opening of the exchange at Manchester on Saturday was proved to be most satisfactory, for the Siemens transmitters, in conjunction with the metallic circuits and an improved receiver that the Mutual Telephone Company have adopted, proved to be so extremely efficient that the speaking on the "Mutual" exchange was at once recognised by the subscribers to be already considerably superior to that obtained on the National Telephone exchange by means of the Blake transmitter. A carbon transmitter of greater sensitiveness will be substituted in August, when it may be expected that a really ideal exchange will be at the service of Manchester, and the sooner we have something like it in London the better. It is a noteworthy fact that the Mutual Telephone Company already have orders for 2,000 exchange lines in Manchester alone. They have been extremely fortunate in obtaining wayleaves, and it is expected that in the course of a very few months their exchange in Manchester will be larger than that of the National Telephone Company.

Athens.—The mystic lamp, burning without oil or wick, seems to thrive at the classic city of Athens. After a year and a half there are 3,838 incandescent lamps supplied, besides 82 private arc lamps and 52 public arc lamps and eight motors, of a total capacity of 50 h.p. During the month of December last the station supplied a total of 200,000 ampere-hours. The gas company now put in fittings free of charge, to keep up with the competition. A large number of the public buildings are now lighted by electricity, and the demand is constantly increasing.

THE
ELECTRICAL ENGINEER.

Published every Friday.
Price Threepence ; Post Free, Threepence Halfpenny.
Editorial and Publishing Offices :
139-140, SALISBURY COURT, FLEET STREET,
LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

'THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms :—*

	3 months	6 months	12 months.
United Kingdom............	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d	17s. 4d.
Other Places..................	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VI. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

We may occasionally follow the lead of our American Contemporaries, especially when they point out a serviceable way. They are not backward in asking their friends to do all they can for the welfare of the paper. We ask our friends to remember us. No Paper that we know ever refuses Subscribers or Advertisers. Nor do we; in fact, we invite them, believing that they will get full value for their money.

Specimen copies of the paper will be sent on request.

THE STRAND.

"The Strand is up again," was the phrase used by a gentleman to us, in a tone of injured innocence, as if he was personally injured thereby. No doubt the breaking up of one of the main arteries of traffic is a nuisance, and causes a tangible loss to shopkeepers, though the loss may be recouped by subsequent advantages. The breaking up of the roads for purposes connected with lighting is recognised as a necessity. The object of local authorities should be to reduce the inconveniences to a minimum. Enquiries, with a view to ascertain the action of the London County Council, prove that that body needs sounder advice than it at present gets. Unless our information is incorrect, the present breaking up of the Strand is for the purpose of laying larger mains through a distance of between four and five hundred yards. The Council have, in the interests of the users of the street, stipulated that the work should be commenced and finished within 14 days. This task may be possible, but it is difficult, as not only have the electric light people to do their work, but the gas workers have to take up one of their old and now unused mains. It is again stipulated that the work shall be commenced at both ends, and it is this stipulation that seems to us open to most objection. It will cause a double block in a busy street—in fact, block the total length all the time unfinished, and make the regulation of traffic more difficult than if only one block took place. The time during which the street is up may be shortened, but if the view above taken is correct, the inconvenience during the period while work is carried on will be considerably greater than if the work was carried on only at one point. In streets where the traffic is not so great it may be convenient to carry out the work by having half a-dozen gangs working towards or from each other, but what is permissible in one case is injudicious in the other. At first sight it seems as if less inconvenience would be caused by working from both ends, but when considered in connection with the enormous traffic the result is doubtful. At any rate, those who should understand the matter are almost unanimous in their opinions. Electrical engineers who have to carry out the laying of mains in streets, are fully sensible of the anathemas hurled at their heads; and would be glad if the authorities would more closely examine the possible result of stipulations before making them, rather than find out afterwards that a different course would have been preferable.

SOME STATISTICS.

It would be interesting if some of the Post Office officials would, amongst the mass of statistics given in Blue-books and reports, make a calculation of the year's saving to the nation owing to the introduction of telegraphy. Fifty years ago, and later, the Government maintained a semaphore signalling system between London and Portsmouth. The annual upkeep of this one line was stated, in a return made to the House of Commons in 1843, to be from £3,000 to £3,500. The signals were available only about 1,600 hours during the whole year. We should like to know the number of words sent by the Government over this semaphore system during a year. The cost per word could then be ascertained. The number of words sent over the telegraph lines between London and Portsmouth during the past year might be given, and the cost of such sending. The cost per word for telegraph messages would thus be known, and the comparison of cost per word could be given, or we could know the total cost to send by a semaphore system. A good many criticisms of costly Government are heard and seen, but few people realise that in many directions an enormously increased amount of work is done now, at a greatly lessened cost, than was possible even 50 years ago. In fact, had not invention come to the aid of civilisation, neither business, population, nor comfort could have progressed so rapidly as they have done. The development of electrical application in all directions has been and is one of the greatest factors in modern progress, yet those who would fain push forward further developments are met with so vast an amount of inertia as often to render their efforts futile.

ALTERNATE CURRENT TRANSMISSION.

During the third and the last of this series of Cantor lectures at the Society of Arts, Mr. Gisbert Kapp dealt very fully with the probabilities of transmission of power electrically by means of alternate currents. The limits of transmission by direct currents is reached when it is necessary to employ two or three thousand volts pressure, and therefore future development will probably—nay, must—be in the direction of alternate currents. In a most graphic and admirable manner Mr. Kapp described the position as it exists. He showed how Ferraris first of all pointed out the right way to get an alternate-current motor that was self-starting, and how Tesla and others had worked in the direction indicated by Ferraris, and, finally, how a three-pole alternate-current motor had been produced that would start, keep in step, and also pick up again though momentarily overloaded. He showed how this was done with the use of—not two—but three line wires to the motor. But the most interesting point was that Mr. Brown, of the Oerlikon Works, was now constructing an alternate-current plant whereby to transmit the whole of the power required by the Oerlikon Works. Here the power will be transmitted from Bulach to Oerlikon, a distance of 15 miles, under a pressure of 25,000 volts. This installation of Mr. Brown's will be watched with the greatest interest throughout the civilised world, for upon its success will depend the introduction of similar plant in many districts where natural water power must be transmitted over considerable distances, if it is to be rendered serviceable to the inhabitants. We have not thought it necessary to give abstracts of these lectures of Mr. Kapp, because they will ere long be published fully in the *Journal* of the society, and when complete can be better discussed than from mere abstracts. Still, the experiment to be made at Oerlikon deserves the widest possible notice, in order that those interested in the subject may know where to obtain information.

COST OF ACCUMULATOR TRACTION.

The recent fierce discussion that has taken place—more perhaps in private than in public—over the cost of accumulator traction should lead to eventual dissolving away of useless speculation, and to the bringing to light of the solid and valuable nugget of real facts about the cost of accumulator working for which the electrical profession has had to wait so long. It is to be hoped that authoritative figures will ere long be given, so that we may know exactly where we stand in this important problem. It is some time now since we were able to announce, as we were authoritatively informed, that a definite arrangement had been made by which sets of accumulators for a certain number of cars, say, 20, were to be maintained by the makers for a definite price of 1d. per car mile run. This itself would at once put the matter on a definite footing, and—notwithstanding the suggestion that the depreciation would be more than this, and that the makers would only have to stand the loss—we are at liberty to believe that some such arrangement could be satisfactorily and advantageously made. The deterioration in the cells results principally from three causes: burning out of the connections, mechanical shaking of the plates, and over-discharge. The first is a matter that slight alteration in manufacture—for instance, the use of copper embedded in lead connections—will obviate. The second—mechanical shaking—is, in reality, we believe, from actual facts before us, not so deleterious to properly-made cells as has been given out, and by far the most difficulty results from over-discharge. The excess of current taken out of the batteries with heavy loads on steep gradients and round stiff curves, rises to something over 300 or 400 per cent. of what it ought to be, and the continued occasional over-discharge wracks the cells far more than the mere shaking of the cars will ever do. This is the fruitful cause of the large depreciation known to have been experienced with some cells. Now, it is the merest truism to say that this over-discharge is not an electrical problem at all. It is, like so many other initial difficulties in electrical work, a mechanical one. The batteries ought so to be arranged with respect to their motors and gearing that no over-discharge of anything like this amount should be ever possible. The problem to be solved, as the merest tyro in traction should know, is this: How to overcome the greatest possible load in starting on the greatest incline on the given line; and the cells should be proportioned to this effort at the rate of discharge given by the makers, and should never be exceeded. It is clear this can only be done by suitable variable gearing connecting the motor to the car axles. Mr. Radcliffe Ward has been one of the earliest of the inventors who have tackled this problem for electric traction; and Mr. W. W. Beaumont, who is another, has produced a most ingenious variable gearing. If we are ever to achieve economical accumulator traction, attention must be given seriously to this part of the subject—gearing to prevent overload of the storage cells; then, and not until then, will the question be finally solved.

MORE AMUSING THAN A NOVEL.

[The following unique criticism appeared in the last issue of our contemporary, the *Electrical Review*. It is so amusing that ordinary practice may for once be suspended, and we may venture to give further prominence to the criticism and the reply thereto.—Ed. *E.E.*]

"First Principles of Electrical Engineering." By C. H. W. Biggs. London: Biggs and Co.

This is a work professing to deal with electrical engineering. If the preface should by any mischance be taken seriously, it will undoubtedly cause dismay in the heart of many a writer whose efforts have hitherto been accepted as worthy expositions of elementary electrical science, and whom, indeed, the author with elegant directness and empty egotism characterises as "fools." We, however, nervously heave a sigh of relief after the author's intimation that "there is very little in the book that will clash with the views of workers like Crompton, Hughes, Hopkinson, Kapp, etc.;" and, further, that "there is no attack or disparagement meant in regard to theorists like Sir William Thomson, Clerk Maxwell, Professors Lodge, Rowland, etc." How thankful we are to receive this modest declaration after observing how far the author goes out of his way to vilify writers of all the elementary text-books!

This is a book in which there is much cry, but little—dreadfully little—wool. We are told, in effect, that it will not deal with the "thoughtless iteration of Thales," but with the supplying of a "working foundation to students whose hope is to become practical men"; presumably, from the title, electrical engineers. Yet, will it be credited, a large portion of it is taken up with considerations of frictional electricity—the Wimshurst machine, Leyden jar, condensers for telegraph working, tangent galvanometer, Daniell, Grove, and Leclanché batteries, elementary propositions in graphic statics, etc., all of which will be found treated in a much clearer and much more reliable fashion in many of the well-known elementary text-books denounced by the author in such unsparing terms, as "the sooner their contents are forgotten the better." The construction and action of arc and incandescent lamps are, however, left undescribed, and there is not a single decent detailed illustration of a complete practical dynamo, transformer, secondary battery, or volt and ammeter, or any illustration whatever of an electric motor.

The book is *full* of mistakes (far more mistakes than there are pages), not only in regard to printer's errors, bad English, and careless revision of proofs, but also in regard to first principles and well-known data. In fact, should a beginner read this book before he has studied any other on this important subject, he will find it difficult to recover from the many erroneous impressions thus first implanted in his mind. Let it, however, be put into the hands of an advanced electrical engineering student, and he will find it far more amusing than any *novel* he ever read, for on every other page he will have the pleasure of detecting the most outrageous and flagrant errors ever printed since electricity became a practical science, and he will close the book with a feeling of wonder and amusement at the assurance of the author in having issued such a crude, careless production. He will, in fact, agree with the concluding remarks of the author's preface, that should it not realise what is required it "had better be burnt by the common hangman than put into the hands of students."

Just to observe one or two of the many hundred mistakes in the book, we find at page 133 the following statement: "Taking that every pound of coal consumed in the furnace of the boiler should give 10,000,000 heat units, what part of this energy is obtained in the working circuit as given by the formula $C^2 R$?" This must be "Heaven-born" coal! Or, perhaps Mr. Biggs has just returned from the infernal regions, where the everlasting fuel employed by his Satanic majesty never dies out! Any ordinary British engineer is only too glad if he obtains little more than $\frac{1}{1000}$th of the above-mentioned calorific value applied to his boilers.

In many places the author confounds between work, energy, and power—*e.g.*, at page 96, he says, "the watt (unit of work?) = volt × ampere (C × E) 746 watts = one horse-power." At page 78 the text is quite unintelligible when compared with the accompanying figure, for the all-important letters, N, S, and R, are omitted. Besides which the author is entirely wrong in asserting that the maximum E.M.F. is generated when the armature coils of a dynamo are moving *parallel* to the lines of magnetic force between the poles of the dynamo!

We withhold further remarks, in view of the magnanimity shown by the author of the book in letting Sir William Thomson, Clerk Maxwell, Hopkinson, Crompton, and others off so very cheaply!

CRITICISING THE ABOVE CRITIC.

To the Editor of the "Electrical Review."

Sir,—May I venture to ask a small space to criticise the critic of my book? I am delighted at the criticism. It is a very creditable performance, and just what might be expected from the pen of the ultra orthodox. The only mistakes to be found are (1) in the method, and (2) in the matter. The former is a kind of shadowless echo from Mark Twain and Artemus Ward. The spirit undoubtedly was willing, but, alas! the brain was weak. My preface seems to dominate all else in the critic's mind; it is the Alpha and Omega of his criticism. May I parody an "Amurican" jingle for the benefit of your critic:

"The *Electrical Review* was asked, Can you suggest a cure
For the debilitated state of certain lit'rachure?
'Ain't none—the author's ignorance is far too dark for lightnin';
While I who know enough to write hain't got no time for writin'."

I would also like to quote for his edification a sentence from Locke, for no doubt, as my critic makes so great a point of grammar, he must be well acquainted with the English classics at any rate—"He that will not eat till he has demonstration that it will nourish him; he that will not stir till he infallibly knows the business he goes about will succeed, will have little else to do but sit still and perish." It is amazing—to your critic; it is astounding, it is condemnable—still to your critic; that the author of a pettifogging little book should have the audacity to think for himself and say so many things that are unorthodox—and therefore wrong. It may be still more surprising to your critic to find that I, at any rate, look upon his criticism as the greatest compliment he could have paid me. Like Balaam, he came forth to curse, but the curses are blessings in disguise. Let us see The views expressed about induction are unorthodox. Has the critic shown they are false? My views as to the use of + and − differently in the external and in the internal parts of the circuit are unorthodox. Has my critic ventured to tackle me on this point? My views as to the constancy of action of a "line of force," and of the "pull of a magnet,' are again altogether unorthodox, but my critic has not ventured to expose the idiocy of my views. So far as orthodox and heterodox views are concerned, the book professes to be heterodox, but the reviewer simply says it is *full* of mistakes and altogether wrong. Of course, from the orthodox view it is; it was intended to be. He fights shy of the heterodox problems, and shines in questions of grammar and lost letters in illustrations. One would naturally imagine that while filled with the divine afflatus—query, inflatus—he would have selected the most vital errors to damn the book. Yet what does he do? He gives three examples. One a stupid blunder, but clearly indicated by the context to be a blunder—where "10,000,000 heat units" is printed instead of "10,000,000 foot-pounds," and no engineering student would be misled for a moment. Another heavy charge is that certain letters are missing in a diagram. This is awful, because, of course, the whole thing is so exceedingly difficult that they must be known to make the reasoning clear. Unfortunately, to support the reviewer's contention, the reader must be unable to say which is his right hand, for the book says N is the right-hand pole. With regard to the third grave charge, I am right, and your reviewer suffering from the hysterical condition consequent upon the nightmare of the preface which weighs so heavily upon him, cannot have weighed the evidence to the contrary of what he states. This champion printer's reader shows clearly that he looks, as he should in such character, for "literals," and misses the sense of what he reads. He has just said that at p. 78 *the text* is unintelligible without certain letters. It may surprise readers to learn that the figure he refers to is *not* mentioned on p. 78 at all, though the figure itself is placed there. The text is on p. 79. The error is not worth mentioning except that those who grovel in the dust with a microscope should be quite sure they are right. To return to the charges. On p. 78, which he must have looked at, I find "the action in the conductive circuit is proportional to the number of loops or closed curves of lines of force," etc. On p. 79, I read "When the conductive circuit, R, is in a *vertical* position the maximum number," etc.; further down, on p. 79, "T is now at the bottom, B, and has now the maximum number of loops around it"; further on still, on p. 79 and turning over on to p. 80, "The number of loops increase till the circuit is vertical." Again, on p. 80, "the number of loops that pass around the conductive circuit, as this determines the electrical pressure and consequently the current." On pp. 81, 82, and 83, the same strain is continued; see, again, p. 106 (by the bye, on p. 107, your critic will find the letters "ere" missing). I might also refer your critic to pp. 114, 115, 116, 117, 154, 155, etc. May I venture to quote again p. 155, "The numbers of lines looping the coil being fewest, practically none when the coil is *parallel* with the lines, and largest when at *right angles* to the lines." I could say much more, and, perhaps, to the point, but as I ask for criticism, not from a proof reader, however great an adept he may be, but from one who knows something of electrical engineering, I refrain from pursuing this point further.

Now, Sir, if your printer's reader wants to show more of his proficiency, please let him put a tag at the end of this after the following fashion. On p. 3 "symmetrical" is twice wrongly spelt; on p. 13 is an "o" wrong fount; in other places an "l" is missing, or an "i," or "nd," or "oil," and so on—dozens of errors; show that "I" is used instead of "me," "it" for "its," an adverb for an adjective, that a comma is misplaced, etc. This kind of thing will amuse him and won't hurt me. As yet he has shown a lion's heart combined with a baby's fist. If he really has got anything to say worth hearing, for heaven's sake let him take up my challenge on page 121 about the use of + and −. A discussion on this point will be such as all can understand. There are some other points I dispute your reviewer's ability to discuss, as he is evidently not fully acquainted with the subject. Still, if he desires it, I have no objection to hear him upon the "unit line of force," the variability or the non-variability of the action or actions of a line of force. The time for the hangman is not shown to have come by calling attention to missing letters and evident misprints. It is my intention to reprint all critical remarks with my comments thereon, as indicated in my preface. This will make a pamphlet equal to a shilling shocker.—I am, yours faithfully,

C. H. W. BIGGS.

Saving Oil.—In engineering workshops 75 per cent. of the oil remaining in the metal cuttings from drilling and planing machines can be recovered by a suitable centrifugal machine. The gain in recovered oil is about 40 to 45 gallons per ton of cuttings.

CORRESPONDENCE.

A TERM WANTED.

To THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—Pray do not charge me with "doubting modern advances" (p. 214). I have heresies enough to defend in doubting whether some fashionable modern theories or hypotheses are advances at all. Marking time looks like marching and makes a great noise, but it can hardly be called advancing. It does seem to me that what are called modern views amounts to this: We know electricity and magnetism only as shown in iron, copper, guttapercha, and so on. We do not know what goes on in them. Instead of finding out what does occur, and waiting humbly for an explanation till we know, let us suppose that the phenomena really occur in something else, which, as no one can contradict, because neither we nor they know anything about it, we can endow with any properties we choose, and change them at pleasure. There we have "the ether"; if it has such and such properties it will explain the phenomena we do not understand: therefore it has those properties. Then we begin at the other end of the chain; the ether, because it has such and such properties, is the cause of certain phenomena which present themselves in matter, and fully explains those phenomena. Then, of course, we promulgate the *cuicunque vult*, and declare doubters unorthodox and heretics.

I have for some time past been trying to manufacture a "term" for the fundamental fact of electricity, but have not produced a satisfactory word; energule would unite energy and matter, and would submit to change as noun and verb, etc., but does not sound quite pleasant. Till such a term is adopted, much confusion of ideas must continue, because the word electricity embraces phenomena and their causes, and two distinct sets of both. It has a relation to matter, and properties which are like those of matter; yet it is quite certain that its most important actions are not those of matter, but of energy. On the other hand, it has been abundantly proved that electricity is not a form of energy. It can be clearly comprehended as the action of energy through the atomic structure of matter. So the term wanted is one which shall express the marriage of matter and energy, and be limited to that conjunction. In fact, we have the analogy of water currents to complete: there we have the material basis, water; we have also the energy conferred by pressure; we express them both in the word hydraulics; we do not confuse the work done in an engine driven by water power, the stream of water led to the engine, and the original source of power in one word, and that—water; but this is just what we do in electricity, with endless confusion of thought as the result.

If that twofold nature of electricity had been clearly kept in view by means of a distinctive name, I think more attention would have been directed to the real operations, and we should have heard nothing about the mysterious functions of ether. If it had been clearly realised that there is in all respects (except the production of magnetism) an absolute identity between the electric current and the hydraulic current, we should never have heard of the notion that the electric energy travels by an outside medium, and that the conductor (absolutely essential) conducts nothing, and is a mere waste-pipe to get rid of energy, which is found to be a nuisance in the ether energy stream. How long will it be before some self-ordained prophet proclaims that what we call energy is the ether, and that ether is the unknown "substance" which we know under the form and accidents of matter?—Yours, etc.,

JOHN T. SPRAGUE.

CANTOR LECTURE

To THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—In your last issue the secretary of the General Electric Power and Traction Company, Limited, at the request of his managing director, publishes a correspondence, in which it is stated that the Tables 4 and 5 of

Cantor lecture given by Mr. Kapp at the Society of Arts on Monday, the 16th ult., are entirely misleading, etc.

Now, Table 4 shows the cost of the equipment of the Barking-road line with half-a-dozen 52-passenger accumulator tramcars, carried out by the writer in the spring of 1889 for the Electric Traction Company, Limited, every item of which is accurate, and their details can be furnished, the amount being £6,191. 16s. (see *Electrical Engineer*, February 20). The cars proper are not included in the table, as only those items connected with the running expenses are dealt with. To include the cars would add £1,200 to the total, making it £7,391. 16s., which is, perhaps, not what is desired.

Table 5 gives the running expenses for the full mileage of the line—*i.e.*, five cars in service, running a total of 100,844 miles per annum, being 8·068d. per car mile. This corresponds to the year ending June 30, 1890. It is accurate. It must also be very nearly true, indeed, for the present time, since the five most important items—namely, batteries, wages at depot, drivers, steam plant—remain unchanged, and these five items represent 88 per cent. of the total. The life of the batteries is 10 months, or 300 discharges up to the present time. The cars have now been on the road 21 months, and are working with their second renewals. It is to be hoped that the K-type plates may prove more durable. The end of the present year will show their merits or demerits as compared with the ordinary type.

It is to be observed that the 8d. per car mile corresponds to the full mileage of 100,844 miles per annum, and that the wages at depot are a fixed charge—£677. 6s. a year. The mileage run during the first half-year of 1890 under the charge of the writer was 44,047 car miles, the mileage run during the second half-year (the installation now becoming the property of the General Electric Power and Traction Company, Limited) was 33,794 car miles, or a decrease in miles run, period for period, of 10,252. Is this a measure of the improvements? This low mileage runs up the proportion of shed wages from 1·612d. to 2·405, making the car mile run 8·861d., which is unpleasantly near to 9d.

I must remind Mr. Mackenzie that I left the Electric Traction Company, Limited, at the time of its liquidation, and was in no way connected with the company to which he is the secretary.—Yours, etc., T. Frazer.

114, Broadway, Plaistow, E., March 3, 1891.

ELECTRIC RAILWAYS.

There is little doubt that if electric railways can be made successful undertakings from a commercial point of view—and there seems to be no reason why they should not—the close of the present century will probably mark a considerable extension in their use in Europe. That such railways can be operated satisfactorily is demonstrated by the working of the City and South London Railway during the past three months. If the working expenses of this undertaking do not exceed the ratio of operating expenditure to gross receipts on steam railways—and it is possible that they may be less—and assuming that the present weekly number of passengers carried is conveyed throughout the first year's working, the City and South London line should be a commercial success. However, whatever may be the ultimate results, the fact that the railway can be and actually is worked in a satisfactory manner, has attracted considerable attention both in the United States and on the Continent; and the outcome of this is the conception of several similar projects.

On the Continent three schemes have been advanced. The first is the construction of a level electric railway to connect Vienna and Budapest; the second an underground electric railway in Antwerp; and the third an elevated line in Berlin. The first mentioned railway was to have been built at a cost of 3,800,000 florins, and was to have been financed by the Budapest Commercial Bank. Arrangements were made for an inspecting committee to come to London to inspect and examine the working of the City and South London line, and the Hungarian Minister of Commerce was approached with a view to the granting of a concession to establish the railway, the trains of which were to have been operated from six generating stations along the proposed route. Unfortunately for the promoters, and possibly fortunately for the reputation of the electrical profession in the present stage of electric traction, the Hungarian Minister of Commerce refused last week to give his consent to the carrying out of this gigantic scheme; and there the matter terminates for the time being.

The second project, which has just been advanced in Belgium by a Liege syndicate, headed by Baron Sadoine, the well-known director of the Cockerill Works, comprises the construction of two tunnels under the River Scheldt so as to connect Antwerp with the left bank of the river. One tunnel would be built for a steam railway, whilst the other would contain an electric railway. The river is very wide at the point at which the tunnels would be built or laid, and they would be constructed so as not to interfere with the navigation of the river; the draught of the large Red Star Line steamers frequenting the port being a maximum of 28ft. The proposed electric railway is attracting more attention than the steam line.

The third scheme refers to the construction in Berlin of a southern electric railway between the Silesian Station and the Zoological Gardens Station. The Ministry of Public Works have had under consideration for ten years a project for the building of a railway to connect the south-eastern, south, and south-western portions of the city, and to form a connecting link between the Ringbahn or circle railway, and the Stadtbahn or town railway. For some reason or other, the line has never been established, although the need of it has been long experienced, and there do not appear to be any great difficulties in the way of carrying out the scheme. Now, however, Councillor von Siemens, in conjunction with other promoters, has elaborated a scheme for the construction of a high-level electric southern railway to supersede the proposed steam line. This electric railway would comprise a double track, would be carried overhead on standards, and passengers using the Ringbahn or Stadtbahn would only have to walk a short distance to arrive at the electric railway. The railway would cross the River Spree by means of a bridge just above the Oberbaum Bridge, and the trains would travel equally as rapid as those on the town and circle lines. This scheme is to be considered by the Municipal Council and it will also be submitted to the Minister of Public Works, whilst the Antwerp project will be referred to the Town Council.

UNDERGROUND MAINS.—V.

THE BROOKS OIL INSULATION SYSTEM.

This system, the invention of Mr. David Brooks, of Philadelphia, embodies the use of heavy mineral oil—one of the best of insulators—as the dielectric for high-tension underground mains. The system has recently been brought prominently to the front in this country by Messrs. Johnson and Phillips, the representatives of Mr. Brooks in this matter on our side of the Atlantic. The system has, however, been well known for many years, and has received much favourable commendation, in this country from no less an authority than Mr. Preece, and in America numerous experts have testified to its efficiency, and dating back as far as 1877, in which year Mr. Brooks laid some experimental wires in Philadelphia.

In 1887, a line of 1⅓ miles was laid by Mr. Brooks on the Pennsylvania Railroad. In this cable there were 18 splices and 53 conductors, and a very high insulation value was obtained, and an important feature in reference to telegraph and telephonic circuits was practically demonstrated—viz., its low inductive capacity, which in this case gave a mean value of about ·212 microfarads per mile.

The experience in America of over 10 years, though almost exclusively telegraphic, amply demonstrated the permanence and efficiency of the system. Mr. Brooks claims in reference to these circuits that while other multiple cables have frequently broken down and developed faults due possibly to lightning and other causes, that his circuits have never given way, and continue to this day to give values as high as when the lines were first put down.

In the earlier experiments Mr. Brooks employed ordinary fluid mineral oil as insulating medium. This, however, was found to have a very high penetrating power, and continual care was needed to keep the oil confined. The oil now adopted, produced from the waste products of rosin oil, is a thick sticky mass less liquid than treacle, and has the advantage of being extremely cheap.

Practical details have now been carefully worked out, and it may be confidently stated that the Brooks system, well carried out, has the best claims of permanency and efficiency of any underground high-tension system, and that it will probably contrast favourably as to cost with any other system of anything like similar insulation and permanency.

The dielectric is a pure homogeneous thick fluid of extremely high insulation value. It does not oxidise when exposed to the air, and when occupying the whole of the space in an iron pipe beyond that occupied by the conductors and their fibrous covering, possesses all the elements of permanency—in fact, theoretically the system seems to exclude all the ordinary factors of decay, and the permanence of the system seems only limited by the life of the containing pipes, which, in ordinary cases, we believe have been known to last over 20 years when used for gas or water, where it must be remembered both the inside as well as the outside of the pipe is exposed to influences tending to cause decay; whereas in the Brooks system it is evident that no decay of the pipes could go on from the inside, and any deterioration that took place would be limited to the oxidising and perishing process from the outside only. Hence it is urged with much show of reason that the Brooks system must rank well, not on the score of insulation alone, but on that of permanency.

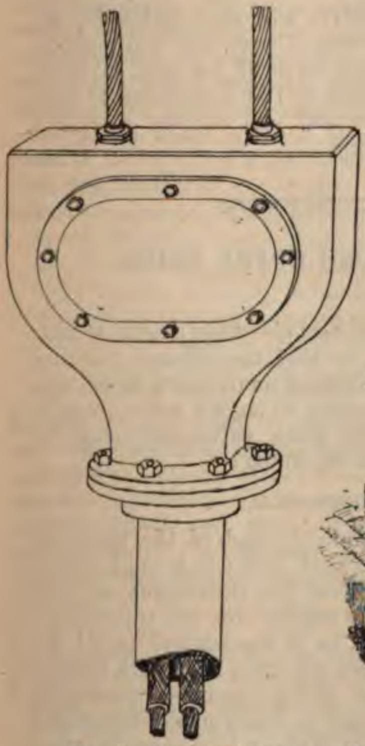


FIG. 3.—Terminal Box.

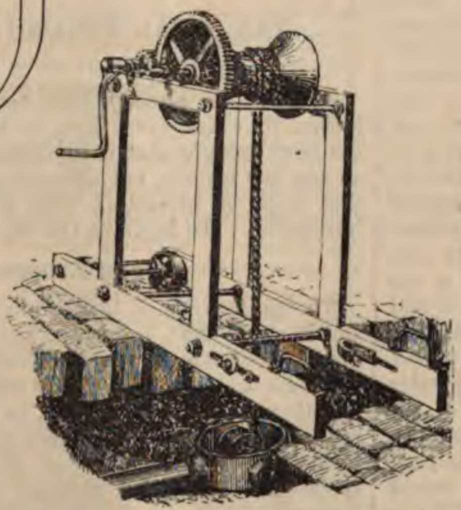

FIG. 6.—Winch for Drawing in Cables.

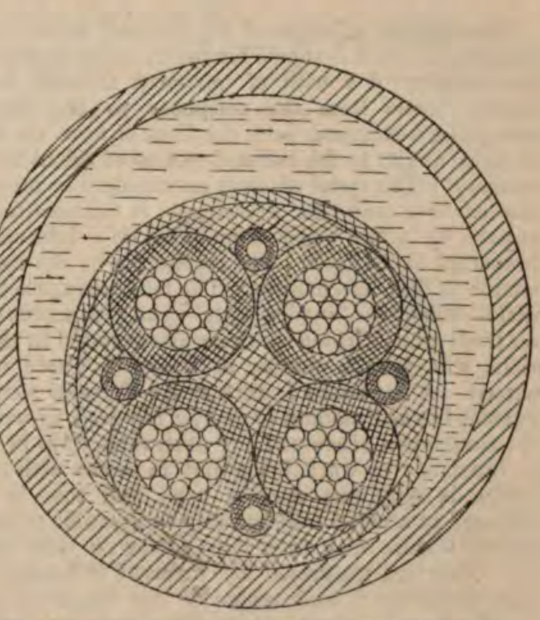

FIG. 4.—Section of Underground Mains, with Oil Insulation.

The mechanical details of the Brooks system are seen in the accompanying cuts, larger details of which will be given next week.

FIG. 1.—Brooks System of Underground Cables in Iron Pipes.

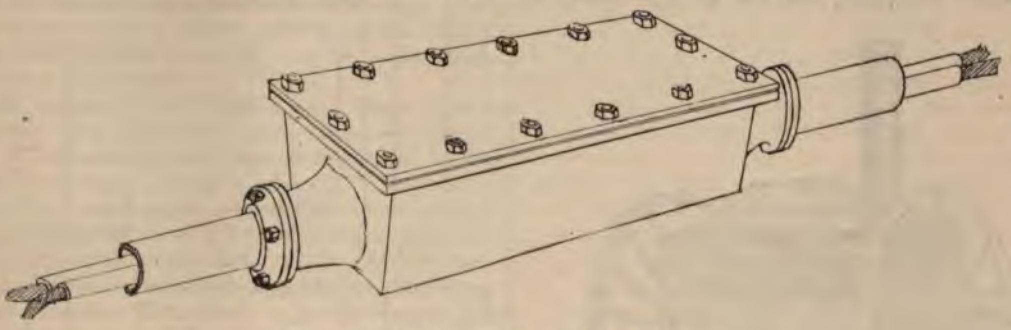

FIG. 2.—Drawing in Box. Brooks System.

The iron pipes are used in the usual lengths made and kept in stock, and have their ends carefully bell-mouthed, and connected together by T-sockets, as shown in the small cut, Fig. 1, and at suitable distances draw-in boxes, Fig. 2, are provided, which may or may not have glands for the cables to pass through, according to circumstances. Branch circuits are taken off by means of junction-boxes fitted at points determined upon. The junction-boxes are in all cases provided with glands for the cables to pass through, so that the fluid dielectric may be removed from the junction-box for the purpose of making a branch connection, or for testing purposes, the glands then preventing the dielectric from flowing into the box from the pipes containing the mains.

The branch connections connected thereto are preferably lead-covered cables of the ordinary type, which also pass through glands. The junction-boxes may also contain fuses between the branch circuits and the mains. The terminals are formed of cast-iron boxes of special form provided with glands with suitable vulcanite sleeves, through which the ends of the cables are brought, Fig. 3. At the highest point of the line a tank or cast-iron box with removable lid is provided, which is occasionally examined and kept charged with the fluid dielectric, so as to ensure the whole system being fully charged. A small trench having been dug and a section of the line having been prepared and all joints in the pipes carefully made, the cables, which consist of ordinary stranded copper conductors, covered to a suitable thickness with raw jute or hemp strand, preferably by braiding, and again wound over all with a sewing of braiding, are coiled on drums and placed in a tank of the fluid dielectric and carefully heated up to about 300deg. F., and maintained at this temperature sufficiently long to drive off all moisture. The cable may be of suitable size, and composed of varying number of strands; that shown in section, Fig. 4, consists of four cables of $^{19}/_{13}$, with four pilot wires of No. 12 gauge. The end or ends are attached to a hauling-in strand of wire or rope previously passed into the pipes, and the cable is drawn in direct from the hot dielectric, Figs. 5 and 6, by means of a winch.

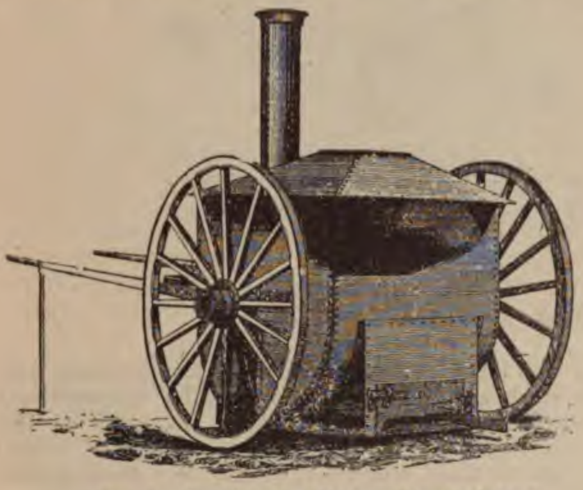

FIG. 5.—Cauldron for Heating Brooks Cables.

(To be continued.)

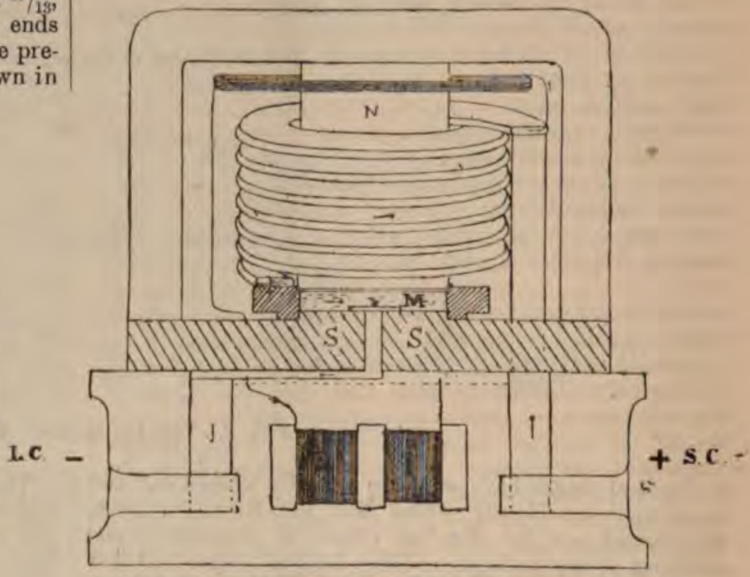
FERRANTI ELECTRICITY METERS.

The essential principle of the Ferranti meter (a sectional diagram of which is shown herewith) is the measurement of the rotation of a bath of mercury through which the current passes from the periphery to the centre after energising a magnetic field, the lines of force of which are at right angles to the radial direction of the current in the mercury. The speed of rotation increases in proportion to the current, and the movement is transmitted to the register by a fan which is mounted on a light spindle and immersed in the bath. The registering of the meters is as simple as their mechanism. The faces are marked with six dials—units, tens, hundreds, etc.—and the amount registered on these when divided by the constant stated in the instructions, will give the number of Board of Trade units consumed. A important feature of the Ferranti meter is the extremely small amount of energy required to work it, and the consequent absence of any observable drop in volts, due to resistance or work being put in series with the lamps. There is only one moving part, and this is perfectly enclosed in a metal case, entirely inaccessible to any of the defects a more open form must sooner or later be subject to. They are unaffected by external influences; indeed, the correctness of their record is not impaired (as would be the case in some other direct-current forms) by a magnet being placed near them, as might be done by a dishonest consumer.

They are, in brief, motor meters of the simplest attainable form, and as such do not require to be touched for winding up or recalibration. They are made entirely of uninflammable material, can be quickly installed and connected, and are suitably designed to prevent their being tampered with afterwards, unaffected by external influence.

As regards accuracy, a great disadvantage of some other forms of meter is their inability to start registering at a small fraction of their full load, that is to say, when the friction of the working parts is greatest relatively to the force to overcome it. A consideration of the design of the Ferranti meter will show that in it this friction is at a minimum, but even so far its effect is largely reduced by a simple and effective device, the "compensating coil," which is the patent of the makers.

This device consists of a fine wire coil (in some sizes of direct-current meters the residual magnetism of the field is arranged to take effect and the fine wire coil is dispensed with) through which a minute shunt current passes round the iron core and produces a strong magnetic field relatively to the small current passing through the bath at low readings.



M shows the Mercury Cup. L C indicates Lamp Circuit.
S C indicates Supply Circuit.

By this means Ferranti meters will start registering at about 1 per cent. of their limits of load, and will register with less than 3 per cent. error over 97 per cent. of their working range—*i.e.*, for instance, a 100 ampere-meter will start registering at 1 ampere, and will register correctly from less than 3 to 100 amperes.

THE ROYAL ENGLISH OPERA HOUSE.

So much has already been said about the degree of perfection to which everything in this magnificent building has been brought that it is, perhaps, unnecessary to enlarge on any one feature, but electricity so largely contributes to this state of perfection that some particulars may be interesting. To begin at the beginning:

THE ENGINE-ROOM.

The engine-room is situated in the back of the building, and is about 20ft. below the road level; it is built with a double roof, which extends over the boiler-room, so that the noise and vibration of the engines are not transmitted to other parts of the house, or if transmitted at all are reduced to a minimum. There are three Marshall's boilers, locomotive type, known as 30-h.p. nominal, producing steam at 140lb., fed through a Berryman's feed-water heater. There are also three Willans high-speed engines of 135 h.p., coupled direct to the dynamo, and running at 350 revolutions per minute.

The foundations of these engines are built up independently, and are not part of the engine-room floor, so that vibration in the house is still further reduced. The main steam-pipe passes over the three engines and the boilers, all of which are in a straight line, and is tapped off on to each, so that in the feed-pipes there is no bend whatever.

The exhaust steam is utilised for a multiplicity of purposes. It passes through three feed-water heaters, the first of which supplies the boilers, and the other two supply hot water to the lavatories, etc., in all parts of the house.

What steam remains is used to warm the building, by means of an ingenious arrangement of pipes, through which the steam passes, and circulating round which is a strong current of air forced through by means of a Verity's silent air propeller, coupled direct to and actuated by an electromotor. The steam generated is thus used to the utmost, and the exhaust steam-pipe which runs to the top of the building has a great deal of spare time on its hands; in fact, most of the steam ultimately finds its way, in the form of water, into an open pit about 50ft. or 60ft. deep, through which the whole of the water is drained by means of two pumps—a Worthington and a Pulsometer.

Dynamos.—Each dynamo, with its engine, is bolted on to one bed-plate, and has a clear space of 4ft. all round. Two light overhead travellers are so arranged along the length of the engines and dynamos that they may be easily taken apart for repairs if necessary.

These three dynamos are Siemens new type shunt-wound machines, each capable of giving 650 amperes and 110 volts at 350 revolutions, and are all connected to the main switches in the engine-room in parallel. Any two of them are capable of doing the whole load, and the third one is always in readiness, and is kept moving *slowly* every evening for a short time to see that it is in order. Each dynamo has a pilot lamp across the terminals. The regulation of these machines is entirely done by means of a hand resistance in series with the fields, and the stop-valves are left full open all the time. The E.M.F. is shown by a Cardew voltmeter with a 12in. dial, a gigantic needle, and figures that may be read at the other end of the engine-room with ease. As is the case in nearly all theatres, the load is subject to great variations, and in this particular opera the load varies some eight or 10 times in the evening from 1,400 to 300 amperes.

In addition to the spare dynamo and engine, two sets of 54 31L accumulators have been provided to supply light to the front of the house in case of any serious accident to the machinery, but they can be used for any circuit should it be necessary. They are arranged in three groups of 36 cells each when being charged, and are charged by one of the dynamos at 100 volts during the daytime, and are used for a short time every day to keep them in good condition. These cells have very commodious quarters of their own in a separate room, which is thoroughly ventilated, and they are so arranged on shelves that anyone of them can be got at without the least difficulty. The ventilation of the house, as well as engine-room, boiler-room, etc., is done electrically in the following way: Fresh warm air is forced into each tier in six places on the walls through air channels by the air propeller referred to above, and each ceiling is supplied with large gratings communicating with other channels leading to a chamber in the roof containing another large air propeller electrically driven, which carries away all the bad air, and makes room for the fresh supply. A third motor and fan fitted in the top of the dome also contributes to the ventilating arrangements. In the engine-room the ventilating fan is fixed at the end opposite to the boilers, so that all the bad air is forced into and carried away by the furnaces, and fresh air supplied in its place; this arrangement was necessary, as it would have been impossible to ventilate the engine-room into the street.

THE STAGE.

On the O.P. side of the stage there is a very complete system of bells and speaking-tubes to all parts of the house, made by Messrs. Adams and Co. These tubes are all put in a large case, and are arranged so as to return to their places when released after use. In the middle of this bank of tubes are four push buttons, which serve to set the artificial thunder in motion. The use of electricity to produce thunder is most appropriate.

To return to the electric lighting arrangements. Above and to the right of the bells and speaking-tubes is a platform for the accommodation of the man in charge of the lighting.

In front of this platform is a large case containing a pair of Cunnington patent fuses for every circuit in the house. Underneath this case are fixed all the switches; and below these, again, the levers for regulating the resistances in the stage lights.

Of the four pairs of main leads from the dynamos, three go direct to the stage, and one pole only of the fourth goes straight into a room entirely devoted to the resistances used for all lamps throwing any light on the stage. These resistances are all of bare platinoid wire mounted on porcelain insulators.

The lowering and raising of the lights is done by means of a series of small wheels supplied with handles, fitted independently on an axle running through them all. The hand wheels communicate by means of endless wire ropes with switches, which control the resistance by short-circuiting some of the coils in circuit. The method does away with all sparking, and if the switch should get out of order it does not put the light out, but merely introduces all the resistance into the circuit. A large lever at the end of the axle enables all the lamps in the building that are supplied with resistances, taking a little one 1,000 amperes to be raised or lowered simultaneously, while the independent hand wheels can be utilised to vary any desired combination. The limits of variation are from 110 to 50 volts.

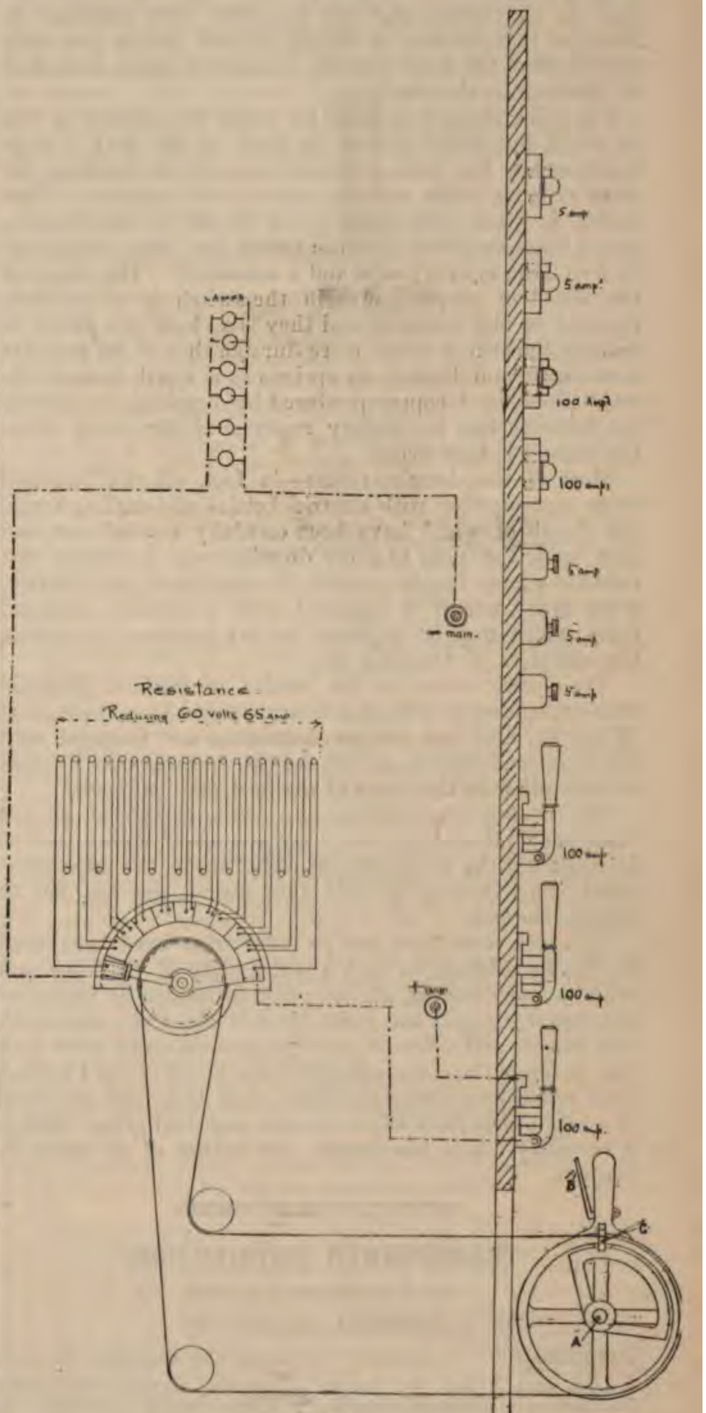


FIG. 1.

The accompanying sketch, Fig. 1, shows diagrammatically the arrangement of the fuses, switches, and resistances.

All the levers for controlling the resistances are mounted loosely on the main axle, A, and may be moved independently by pressing the handle, B, and liberating the tooth, C.

The room devoted to the resistances is also thoroughly ventilated.

The battens, of which there are seven, are all wired in three circuits, and can consequently be fitted with red, blue, and clear lamps if required, as is the case with the hand battens for the sides. These hand battens contain 36 lamps each—12 blue on one circuit, 12 red on another, and 12 clear over on the third—and are provided with switches so arranged that the man in charge of each batten can vary the colour of the light himself, or they can all be controlled by the man on the platform.

For quick changes of scene for which the curtain is not let down, but which have to be done in the dark, a large main switch has been provided, capable of breaking the main circuits while running with 1,400 amperes. This switch is fitted with copper gauze blocks to take the arc, and is short-circuited after the circuit has been completed by two large mercury cups and a connector. The object of the blocks of copper gauze in the switch is to facilitate renewal of the contacts, and they also have the effect of making the switch much more durable than if the contacts were made and broken on springs as is usual, because the small globules of copper produced by breaking the circuit are flattened into the spongy material of the gauze when the contact is next made.

Most of the dressing-rooms—in fact, all the principal ones—are supplied with electric kettles and curling tongs, the details of which have been carefully carried out, and just inside the door of every dressing-room is a switch that controls a lamp for the general illumination of the interior, while every mirror is supplied with a suitably arranged lamp, which may be adjusted to any position to facilitate the operation of "making up."

The electric stoves for the kettles are made of platinoid wire embedded in cement and surmounted by a thick sheet of copper, and the kettles themselves are supplied with thick copper bottoms, so that the two surfaces may lie close to each other so that none of the heat may be wasted.

The curling-tongs heaters are made somewhat on the same principle, except that they are made hollow, and to be made hot the tongs are put right inside, the heat generated being limited, so that they cannot get too hot to damage the hair.

Although electricity and its accessories have been used in this installation for such a multiplicity of purposes and with so much success, all its possibilities are by no means exhausted; but, at the same time, if the stage managers, and lessees, and actors of past generations could come back and examine the completeness of this house of the Pierides, they would be gratified to think that they had not lived in vain in that their efforts in the past had given birth to a necessity which has become the mother of so much invention.

TRANSFORMER DISTRIBUTION.*

BY J. SWINBURNE, MEMBER.

(Continued from page 216.)

PARALLEL RUNNING ACCORDING TO ARMATURE REACTION THEORY.

Last year I had the honour of reading a paper before this Institution on armature reactions in direct-current machines. In it I showed how the performance of large machines could be foretold; and the whole question of the effect of the armature current on the field magnets was discussed with some minuteness. I cannot pretend to treat alternate-current machines with the same exactness, but still a great deal is to be derived from the study.

It has sometimes been assumed that a machine has self-induction in the armature, and also that there are armature reactions to be considered, and the two actions are treated as if their joint effects had to be taken into account. This view is, I submit, erroneous. Imagine a battery with its cells connected to a number of contact-pieces, and imagine the middle cell connected to a terminal, to represent one terminal of the machine, and the other terminal represented by a rubbing contact which is moved backwards and forwards over the cell contacts by a crank and connecting rod. This gives the analogue of a hypothetical machine with no self-induction. If a choking coil is put in circuit, the hypothesist's alternating machine would be produced. To get a constant coefficient of self-induction in a real machine would be almost impossible. If a coil passes between two cheeks of laminated iron, its coefficient of self-induction is constant. In a dynamo, however, half the iron is cut away, the remainder forming the pole-pieces, and this remainder is not laminated. Even if a dynamo gave a curve of sines at no load, therefore, the reasoning already given would not be accurate, as L would vary considerably from one part of the period to another.

The term "self-induction" is also used somewhat loosely. Engineers do not generally think of electrical inertia now. By a self-induction 1 in an electric circuit is meant that if there is a current of 1 in it, it is interlinked with one line of induction. The idea of self-induction is naturally inseparable from the notion of magnetic induction being interlinked with the circuit. Another way of looking at it is to say that if the current increases there is a back E.M.F. proportional to the rate of growth of the current, and to the self-induction of the circuit. In an alternate dynamo the first definition is meaningless, because there is a field produced by the magnets; so, when the machine is still, there may be a large number of lines of induction through the armature coils without any armature current. If the second definition is taken, there is likewise an E.M.F. produced by the passage through the field, apart from the effect of the armature current.

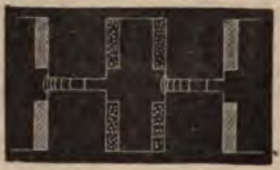

FIG. 3.

Take the case of a machine like the Siemens, with coils passing between poles. If there is a continuous current in the armature, in some positions it will assist the field magnets, and in others it will to some extent weaken them, while in intermediate positions it has no effect on the magnets as a whole. In an alternate-current machine, though the armature current is alternating, relatively to the field magnets it is direct. If a series of instantaneous photographs of the armature current could be taken, each part of the air space would have its direct current.

Fig. 3 is a diagram of the field-magnet poles of a machine. There are supposed, for simplicity, to be twice as many pairs of poles as there are armature coils. If one side of a coil is between each pair of poles, if there were no armature current the fields would be inducing a maximum pressure. If the pressure curve of such a machine were traced, and placed in the diagram of the poles, it would be as shown in Fig. 4. The positive direction of the current or pressure in the armature and field-magnet coils is shown by shading, the negative by dotting. If electricity flows in the armature when the sides of the coils are in the active fields, one side of the field between the poles is strengthened and the other weakened, as shown in Fig. 3. This action is fully explained in the case of direct currents, in my paper already referred to; but in alternate machines the action is much more complicated, for there is no longer a continuous succession of conductors each carrying the same current as it passes any given position. If the pole-pieces were laminated, the distribution of field would vary as each conductor passed; but as it is not laminated, Foucault currents developed in the pole-pieces tend to check variations under influences varying from 200 to 600 per second. The field thus becomes stronger on one side. The curve of pressure thus gets displaced, as shown in Fig. 5.

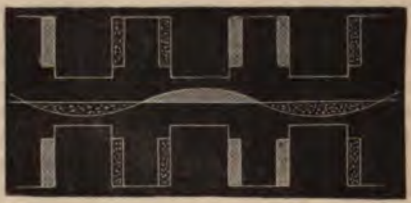

FIG. 4.

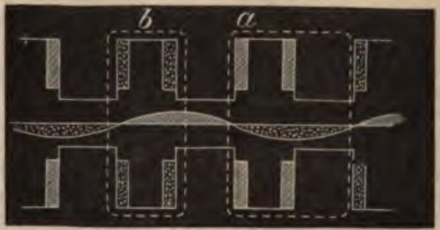

FIG. 5.

If the external resistance is non-inductive, this may be regarded as a current curve. It will be seen that each magnet is now exposed to the back induction due to the armature current. A circuit, *a*, taken round the field-magnet circuit is interlinked with the whole wave. The line integral is not changed if it is taken round any other circuit, so that the sides are the same distance apart as they are in *a*. A circuit taken as shown at *b*, however, includes only half a wave; so that from Fig. 5 both the cross and the back induction could be completely worked out. In most machines it is impossible to make such a diagram accurately; but in others, such as drum armatures, with poles and coils of given widths, it is not so complicated.

---

* *Paper read before the Institution of Electrical Engineers.*

The effect of the armature current, then, is first to make the current lag relatively to the position of the field magnets, and then to lessen the pressure as a whole. It thus resembles the effect of the insertion of artificial self-induction.

I think to call all this "selt-induction," and to assume the harmonic law just to make calculation easy, is disguising the real nature of the action, and may lead to very serious errors. The armature reaction theory is also infinitely easier to understand, and to follow in one's head. The result of it is, in short, that if the current lags, the field is weakened; if it leads, the field is strengthened. If the current is in the direction agreeing with the E.M.F. of the machine, it tends to lag, owing to cross-induction; if it is against the E.M.F. of the machine, as in the case of a motor, it tends to cross-magnetise the fields in the opposite direction.

We may now examine the question of parallel running from the armature reaction point of view. Though it may be out of its proper place in the paper, the question of motors may be to some extent discussed at the same time.

Suppose, as in the first case, a pair of terminals in connection with a station, so that the E.M.F. on them is independent of any current, or the machine under discussion connected to them. It is necessary to keep clear for the moment of any ideas connected with L. The armature circuit must be regarded as devoid of "self-induction."

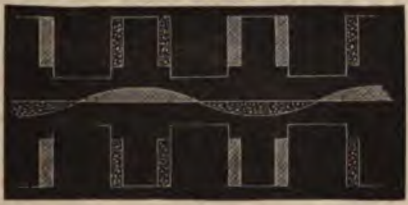

Fig. 6.

A machine without friction may be imagined, and when its field magnets are separately excited, so as to give an E.M.F. exactly equal to that of the mains when it is connected so as to be in step, it runs as a motor taking no current. At each instant the E.M.F. of the machine is exactly equal to the E.M.F. of the mains, so no current passes. On putting on some load the machine begins to lag. As soon as the machine lags, a current passes through the armature. The current due to the difference of two equal alternating E.M.F.'s is not in step with either of them. This is shown in Fig. 6, where two pressure curves are drawn a little out of step. The current through resistance is proportional to the shaded parts. If the E.M.F. of the machine were still the same as that of the mains, it would still develop no power as a motor, because at some parts of the period it would be supplying power to the mains, and at other parts the mains would be supplying power to the armature; for at any instant the armature current would be equal to the difference of the two E.M.F.'s divided by the resistance of the armature. The average current curve is shown in Fig. 7. The

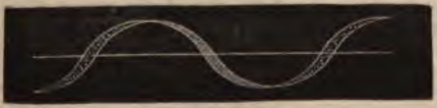

Fig 7.

E.M.F. of the machine does not, however, remain equal to the main E.M.F., merely differing from it in phase, but is decreased by the reaction of the armature current on the field magnets. The average current curve shows that there would be considerable back induction, or many ampere-turns tending to weaken the field. This weakening of the field by the armature reaction allows the main also to supply a current against the E.M.F. of the machine, so that it acts as a motor, and power can be taken from it. If the load is altered, the machine will increase or decrease its lag, so that its effective field is reduced to just the right value to allow the machine to absorb electrically the power taken from it mechanically. As lag is necessary in order to weaken the effective field, so the current in the armature is no longer in step with the E.M.F. of the mains. The result of this is that it is not at the maximum value at the same instants as the E.M.F. is; so that the power taken by the motor is less than the product of the effective E.M.F. of the mains and the effective current of the machine. The E.M.F. and current may be so much out of step that the power of the motor is small, though the armature current is large. The availability of the machine as a motor thus depends on the resistance of the armature, and on its reaction on the field. For instance, if the machine has very little armature resistance, a very small reduction of its E.M.F. will allow a large armature current to pass. If, on the other hand, the armature resistance is high, the armature must have a large reaction on the field so as to reduce the effective E.M.F. If, at the same time as the load is put on the field of the motor is artificially weakened by reducing the excitation—for instance, by the insertion of resistance in the field circuit—the E.M.F. of the machine may be reduced enough to allow current from the mains to act in step with the main E.M.F. For instance, if the supply circuit is of 2,000 volts, and if an ordinary separately-excited 2,000-volt machine is connected, and excited so as to give 2,000 volts with the same frequency, and if this machine is loaded as a motor with 40,000 watts, or 54 h.p., it will lag until the field is weakened enough to let enough current pass to give the power. This current will be more than 20 amperes; but if the machine as a dynamo can give 20 amperes with the loss of 100 volts in the armature, due to the resistance, and if the machine is excited so as to give 1,900 volts on open circuit at the normal speed, and is then thrown into the circuit at an instant when it is in step, and a load of 38,000 watts, or 51 h.p., taken out, it will remain in step, for the E.M.F. of the machine is always just enough below the main E.M.F. to allow the right current to pass. The effective current is then 20 amperes. The main circuit thus supplies 2,000 volts and 20 amperes. Two thousand watts are lost in overcoming the resistance of the armature, and 38,000 are available at the pulley. The losses by friction and Foucault currents are here neglected for the sake of simplicity. In practice a little less than 51 h.p. would be obtained for external use. If the field has not been weakened by reducing the excitation, the effective current—that is to say, the root of the mean square of the current, or the current as measured by an electro-dynamometer—would be more than 20 amperes, so that there would be an extra loss of power in the armature.

If the machine is to be worked as a generator in parallel with the main circuit—that is to say, if it is to supply power to the mains instead of to take it from them—the same reasoning holds good. If the machine is excited so as to give 2,000 volts at no load, and is thrown into circuit at an instant when it is in step—if the engine supplies just enough power to overcome friction, there will be no armature current, as the E.M.F. of the machine will, at every instant of the period, be exactly equal and opposite to that of the mains. If the engine supplies just a little too much power, the machine will begin to lead, and an armature current will pass, which will strengthen the fields by reaction, and the machine will at some instant act as a generator, because its E.M.F. is now a little higher, as the armature current has strengthened its field. Similarly, if the steam of the engine were completely shut off, the machine would lag until it worked as a motor. If now the steam is turned on until the dynamo supplies 40,000 watts to the mains, the machine will increase its lead until the armature current strengthens the field enough to give the full output. The armature current must be out of step with the E.M.F. of the machine.

In the examples back induction has alone been considered, but the effect of cross-induction must also be taken into account. Cross-induction, in the case when the machine is working as a dynamo, makes the current lag. This weakens the field, and counterbalances to some extent the effect of the leading current, due to the pressures being out of step. A still greater lead is therefore necessary to make the machine work as a dynamo. Suppose, however, that the field excitation is strengthened to balance this back induction, as well as the loss by armature resistance—that is to say, suppose it is excited to give 2,000 volts, and 20 amperes on resistance, in spite of the armature reactions—it will run in step on the mains.

It is thus possible by altering the field excitation of such dynamos to make them work well as generators or motors on supply circuits. Instead of depending on the reaction of the armature to strengthen or weaken the field, the field excitation may be automatically regulated, so that the current and E.M.F. of the machine are always in step, or very nearly so.

Take first the case of a separately excited motor. The field magnets may have an additional set of coils, and these are put in series with the main armature current, which is redressed or rectified by a commutator. These coils are arranged so as to demagnetise or weaken the field as the current increases, so that it is not necessary for the machine to lag in order to take a large load.

The machine may be made to excite itself. In that case special exciting coils on the main armature are provided. These are connected with the circuit for exciting the field magnet. If a machine made in this way is used as a motor without a series demagnetising circuit round the field magnets, it begins to lag as soon as load is put on, and the armature current then reacts on the fields and weakens them. As the exciting coils now pass through the same field, this will also lessen the field excitation directly; and as soon as the field is weakened by the armature reaction, the ampere-turns round are also reduced, because the E.M.F. in the exciting circuit is lessened. A very small lag will thus weaken the field considerably, so that a large load may be put on without the lag being great enough to make the machine inefficient. A series demagnetising circuit may be used in addition. If the ampere-turns of the field magnet are not adjusted to the load with perfect accuracy, the machine adjusts itself by lagging or leading very slightly.

Machines with fields excited chiefly by special exciting circuits on the main armatures, and partly by series circuits, may be specially useful for working in parallel as generators. The series circuits are then arranged to magnetise instead of demagnetise. If power is applied to a motor instead of taken from it, it becomes a generator, and the direction of its main current is reversed, both in the armature and the series coils on the fields; so that a motor with a backward series circuit becomes a generator with a forward series circuit. If one machine when used as a generator begins to lead because too much power is supplied to it by its engine, its field is strengthened by the series circuits, and this increases the armature E.M.F. enough to make it give a large output corresponding to the power supplied to it. If machines excited from special armature circuits, without series circuits, are run in parallel, they will keep in step, because the least leading or lagging alters the field excitation.

The compound form is best, because the whole station will then supply the mains at constant pressure, if all the engines are mechanically governed for constant speed of one of them—that is to say, if the whole steam supply is regulated to keep the speed of all the engines constant, the engines taking the steam in proportion to their size. Instead of keeping the speed constant, an electric governor can keep the E.M.F. of the whole station constant. With alternate machines as at present commonly used, it is necessary to alter the field excitation by hand or by automatic gear. Such machines as those described have advantages corresponding to those of compound direct-current dynamos, compared with shunt or separately excited machines. The analogy between these machines and compound or shunt direct-current machines must not be used too far. In direct-current machines, the E.M.F. adapts itself by slight alterations of speed, and the armature reaction depends on the position of the brushes; in alternate machines, the speed is unalterable, and the armature reaction depends on lead and lag.

Prof. E. Thomson tells me that he has been accustomed to send out separate and series excited machines for working in parallel, and that they will work either with or without "equalising connections," such as are needed with direct compound machines. They also work well as motors, and so do the self-exciting machines with separate exciting armature circuits. He also finds the ordinary Thomson-Houston machines works efficiently as a motor.

(To be continued.)

COMPANIES' MEETINGS.

ST. JAMES AND PALL MALL ELECTRIC LIGHT COMPANY.

An extraordinary meeting of the shareholders of this Company was held at Winchester House, E.C., on Monday, at 2.30 p.m., Mr. Eustace J. A. Balfour, chairman, presiding.

The **Chairman** said that in proposing the first resolution—viz.: "That the capital of the Company be increased to £200,000, by the creation of 20,000 shares of £5 each, to be called preference shares, and to be entitled to a preferential dividend at the rate of 7 per cent. per annum on the amount for the time being paid up on such shares, payable out of the net profits of the Company for each year"—he need scarcely dwell on the necessity for an increase in their capital, as the terms of the provisional order under which the Company existed obliged them to extend their operations over the whole area of the parish of St. James. The Directors considered that the original capital ought to be doubled, and there were three ways in which this might have been done. By the creation of ordinary shares, of preference shares bearing a lower rate of interest than 7 per cent., or 7 per cent. preference shares, and they had adopted the latter course as being the best for the holders of the ordinary shares. The Directors intended to offer 10,000 of these preference shares to the ordinary shareholders in the proportion of one to two. He would call attention to an error in the report on this head (*vide* our last issue, p. 223, first column, last few lines of report). In the sentence beginning "referring to the notice," the word "now" should have been written "then," so as to read "then on the register."

Sir John H. Morris, K.C.S.I., seconded the resolution, and it was carried after some criticism of the course adopted by the Directors.

The **Chairman** then put the second resolution, which ran as follows: "That the articles of association before the meeting be adopted as the articles of association of the Company, in lieu of those at present in use as such." He explained that the primary object of the alterations was to enable the shares of the Company to be quoted on the Stock Exchange; they had also taken the opportunity of further remodelling the articles in order to make them work better. Amongst other things, the new articles removed the £1,500 limit to the annual remuneration of the Directors. The Company had not been brought to its present state of prosperity without an enormous amount of very anxious work, and he thought they might fairly claim that their labours, while rewarded with success, had not met with tangible reward in other directions.

The **Solicitor** (Mr. Sydney Morse) then explained the various alterations in the articles, and the resolution, which had been seconded by **Mr. Latimer Clark, F.R.S.**, was carried unanimously.

This finished the business of the extraordinary meeting.

The ordinary meeting was then held. The **Secretary** and **Manager** (Mr. James Strick) having read the notice convening the meeting,

The **Chairman** said: With your leave, gentlemen, we will take the report and accounts as read. The first resolution is that "the report and accounts of the Directors for 1890 be, and the same are hereby, received, approved, and adopted, subject to this alteration, that the word 'then' be substituted for the word 'now' in the fourth line of clause 14 of the report, and that a dividend of 5s. per share, free of income tax, be declared and paid forthwith on the 9,000 shares in existence on the 31st December, 1890."

Mr. Latimer Clark, F.R.S., having seconded this,

The **Chairman** continued: In moving the adoption of the report, there are a few matters which I am sure will be of interest to you—matters connected both with the past and the present condition of the Company. You may recollect that it was at one time the intention of the Directors to propose a scheme for the reconstruction of the Company. Owing to the enormous improvement in our position this has now become unnecessary. The original contract with Messrs. Latimer Clark, Muirhead, and Co. has been practically completed, and, as a result of placing our claim against them for decision by arbitration, we have received an award of over £1,800. I wish to take this opportunity of placing the credit of this fact where it is due—namely, to Colonel Francis. At the same time, even arbitration is a risky, and possibly expensive, resource. And although in this case we have been successful, I am still of opinion that to agree to a reasonable compromise would have been a sounder course to adopt. Owing to expressions of opinion at last year's general meeting, the Directors offered £7,000 (the unissued debentures) to the shareholders. This course was against their better judgment, they considering that it would be better if these debentures could all be held in one hand. Experience has justified their view, for had this been done these £7,000 of debentures would have been converted with the remainder. The Directors hope that the three shareholders who hold these debentures will see their way to converting them into ordinary shares, and it is partly for the purpose of inducing them to do so and partly to deal with the shares not yet on the register, that we wish to substitute the word "then" for the word "now" in the last clause of the report. With respect to the issue of shares in July last, the Directors found themselves, owing to the want of the support of the shareholders, in the position of either guaranteeing to subscribe £2,000 each, or seeing the Company in Chancery. I merely mention this as an interesting practical comment on a somewhat violent attack that was made on them last year by a small body of the shareholders. By a perusal of the accounts, it will be seen that the whole of the profit last year was made in six months, the greater part of it during the last quarter from October to December inclusive. The true profit for the last six months of last year represents for that period a dividend at the rate of 10 per cent. on £100,000, which is an amount largely in excess of the capital at the disposal of the Directors at any time during that period. I do not wish to prophesy, but I can put before you some figures which will, I hope, satisfy you as to our prospects in the future. The output of current during the last two months is considerably in excess of half the output for the whole of last year. The number of lamps wired at this moment is nearly seven times as many as on the 1st of January, 1890, and we have applications for over 10,000 more. The average daily revenue during the last week is not far off six times as large as the average daily revenue during January, 1890, and that although the days are longer. I think, if you will put these figures together in your minds, recollecting that this increase of business is on our original capital, and that it implies but a small increase of staff, that you will agree with us in thinking that you possess a most valuable property, and one likely to be remunerative. And the Directors feel that the results of the year's working have completely justified the course of this Company's business as foreshadowed by them. As negotiations for the purchase of a site in the northern part of the parish of St. James are proceeding, it is undesirable to enter into detail on this subject. The experience gained in the erection of the present station places us in a position of great comparative advantage with respect to the erection of new works, both from the point of view of economy and efficiency. We shall continue to follow the principle of the subdivision of engine power, the adoption of which has been one of the causes of our steady success; and we shall further develop this principle by connecting the new station with the old in such a way that in a case of necessity each can afford the other support. I wish again this year to thank the members of our staff for the admirable and energetic way they have worked, and I wish specially to mention our secretary and manager, Mr. Strick, and our engineer, Mr. Dobson. If any of you knew as much of them as I do, I am sure you would feel as strongly as I do that they deserve our best thanks.

The resolution given at the beginning of the Chairman's speech was then put and carried unanimously.

The re-election of the retiring Directors, Mr. Eustace J. A. Balfour and Mr. Latimer Clark, was moved by **Mr. Hodson**, and seconded by **Mr. Howard**, and carried unanimously.

Mr. Way proposed the re-election of the auditors, Messrs. Deloitte, Dever, Griffiths, and Co., which was seconded by **Dr. Muirhead**, and carried unanimously.

In answer to a remark from a shareholder, the **Chairman** explained that Mr. Latimer Clark was not a member of the firm of contractors, but a director.

A vote of thanks to the Chairman and Directors closed the meeting.

TAUNTON ELECTRIC LIGHT COMPANY.

The fourth annual meeting of this Company was held at Taunton last week, Mr. W. H. Fowler presiding.

The report of the Directors, which was published in our last issue, was taken as read.

The **Chairman** said he was very sorry that the report of the Directors for the present year was not so satisfactory as former ones. The report fully set out the difficulties the Directors had met with, which to some extent had been unforeseen. It took a great deal longer to move from one place to another; it was necessary to do so, and they could not be blamed for the step they took. The accounts showed a loss on the year of £438. 17s. 5d.—that is, after paying 5 per cent. on the £3,000 debenture stock. He had made an estimate for next year, for the whole position of the Company hinged on the income and expenditure. At the present time, with the lamps they had got, and the supply given, they were earning at the rate of £1,500; that was without counting anything at all for new lamps. The profits on installations which they could reasonably hope to carry out he had put at £150. If they made anything like £150 by installation work, their profits on lighting could not possibly be less than £100—they ought to be still more. He had put the profits at one-third of the rents, and he did not think he was overestimating anything if he put their income at £1,800. On the expenditure side, they paid last year for apparatus and renewals £936; that included a large sum for fittings which had been installed. He therefore estimated that in the coming year renewals could be calculated at £400, which would include keeping the machinery in its present high state of perfection. That estimate was rather more than was expended in the year before, when they were at the old place, but the machinery was in better order than it was then. Wages and salaries he put down at £470, which he was informed was the actual amount that would have to be paid. For coal he had put down £500, having knocked off £88 from the figures of last year, when they had coal burning at both stations. He was anxious to overestimate, rather than to underestimate these items. The interest on debentures would be increased from £141. 11s. 4d. to £300 if the additional amount, bringing the amount issued up to £6,000, was subscribed for. This, with the other necessary expenditure, would show a total amount of £1,895 for the year. That showed in round numbers an expenditure of £1,900, against an income of £1,800, or £100 against the Company; and showing the amount of profit earned would pay 3½ to 3¾ per cent. on the debentures. That would be their position, unless, of course, they had a very large increase in the number of lamps, or unless they increased the rentals. There would be £200 to be divided among the holders of the £6,000 of debentures, which would mean about 4 per cent. He did not think they could make out anything else. The Directors would have to consider whether or not they should increase the rentals. Coal had gone up, and, as a consequence, gas had gone up, and he did not see why the electric light should not go up also. A 10 per cent. increase on the rentals would make all the difference between the 3½ and 5 per cent. required for the debentures. There was no doubt they were a pioneer Company, and pioneers always met with difficulties, but he firmly believed that if people could be got to take an additional number of lamps, they would become a very prosperous concern. At the present time they had to raise this £6,000 of debentures. At a previous meeting the shareholders promised to take a certain amount, and he hoped that the Directors would see their way to the remainder and so keep the concern going. If this was not done they would have to face the matter in the way of reconstruction, but as at present advised he did not think it would be necessary to adopt that course. If the whole of the debentures were subscribed for, the Directors would be in a much better position to see what should be done. There was no doubt about this, that if the whole of the machinery were running at its full power they would be doing a large business. He hoped they would see their way to carry the concern on for 12 months, and that shareholders would recognise the necessity of getting people to take the light—for the light must be had, whether this Company supplied it or not—and so doing their best for the interests of the Company. He moved the adoption of the report.

Mr. H. G. Massingham said he would second the motion. As the largest shareholder in the Company, he regretted that there was no dividend. The past year was a very abnormal one, and increased expenditure was occasioned by the running of the two depots for some time, and the delay caused by the very stringent regulations of the Board of Trade in the arrangements of the circuits. At the same time he took a more hopeful view of the position of the Company than did the Chairman. There was, in his opinion, a bright future for the Company. He remembered that in the early history of gas companies they had difficulties to meet, and it took them a longer time to get over them and become successful commercial concerns, than he considered it would electric light companies. He referred to the efficient condition of the plant, which was at present only running at one-quarter of its power, so that without any additional expenditure of plant a great extension of business might be made. Since the formation of the Company they had paid 16 per cent. in the way of dividends, or, including the present year, an average of 4 per cent. per annum.

The **Chairman** said it must not be understood that he advocated the payment of 3½ per cent. on the debentures. They were guaranteed at 5 per cent., and that would have to be paid whether it was made or not. If the profit was not paid the £100 would have to be capitalised.

The report was then adopted.

Mr. G. H. Kite moved the re-election of Mr. A. Lewis as a director. They all knew that the Directors gave up considerable time to the working of the Company, and during the past year they must have have had a great deal of anxiety. As a shareholder, and as the solicitor to the Company, he did not take a desponding view of the position of the Company—he was rather disposed to look at it in the same light as Mr. Massingham did. The Company had come to that crisis when it wanted outside help to make it a paying concern. The light had been taken up in Taunton in a manner far exceeding early anticipations, and it would be a great pity if shareholders allowed it to collapse for want of capital. The Company was possessed of one of the most complete depots outside of London, and was in perfect working order. What was wanted was that the shareholders should put their shoulders to the wheel and obtain new customers; if they did so, he believed that by this time next year the Company would be in as prosperous a condition as they could wish. The shareholders should also do their best to obtain the debenture capital, as in that way they would be enabled to earn a dividend for the ordinary shares. The original debenture issue of the Company was £3,000, which was secured on the first mortgage of the Company's works and plant. Without increasing the debenture issue they had more than doubled the security, so that there need be no fear that there was not sufficient security. The debenture holders, if the worst did happen, would be able to take the freehold premises and machinery and sell them, they could carry on the works, or form a new company, and they would have a great bargain in obtaining them for £6,000.

Mr. W. Potter seconded the motion, which was agreed to.

A motion having been carried re-electing Mr. H. G. Massingham as a director, that gentleman replied, and spoke of the probability of the holding of an electrical exhibition in Taunton during the autumn. Such a scheme could be carried out with the cooperation of the Directors and the railway company, and would do much to popularise the use of electricity. He believed in the future of electricity as an illuminant, as well as a motive power. For some time past, as they were no doubt aware, they had been supplying power for blowing the organ at St. John's Church. In course of time this branch of the business could be increased.

In moving the re-election of Mr. A. Goodman as auditor, **Mr. A. Chapman** said that he (the speaker) had prepared an estimate showing the earnings of the Company if the plant was fully worked. They had four dynamos for arc lamps, three of which were being worked. If the four were worked it would give them a revenue of £1,500 a year; they had two incandescent machines capable of lighting 1,200 lamps of 16 c.p., which would mean a rental of nearly £1,000 a year, and another dynamo working the storage battery. They could make £2,500 a year on an expenditure of but little more than £1,900, including the interest to debenture holders. This would leave about £600 to be divided amongst the ordinary shareholders.

The motion was adopted.

A vote of thanks to the Chairman terminated the meeting.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.

The twenty-seventh ordinary general meeting of this Company was held on Tuesday at the offices, Old Broad-street, Sir G Elliott, M.P., presiding.

The **Chairman** said they had laid during the year 4,000 miles of submarine cable, and they had manufactured a considerably larger quantity. Part of these contracts remained unexecuted, and the work was going on in the present year, the prospects of which, he was glad to say, seemed very encouraging. They were at the present moment laying a cable from Madras across the Bay of Bengal, and loading another cable at their works for the Indian Ocean. He hoped they would continue to be satisfied with the dividend of 20 per cent., which the Directors were enabled to pay, leaving something as a nest-egg for the current year.

The motion to adopt the report and accounts was carried, as also were others re-electing the retiring Directors and Auditors.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The receipts for the week ended February 27 amounted to £5,998.

Bell's Asbestos Company.—Mr. Henry Heywood, of the firm of Heywood Brothers, of Cardiff, has joined the Board of Directors.

Eastern Extension Telegraph Company.—The receipts for February were £43,833, as against £38,466 in the corresponding month of 1890.

Eastern Telegraph Company.—The traffic receipts for the month of February were £59,155, against £53,347 in the corresponding period of 1890.

Cuba Submarine Telegraph Company.—The estimated traffic receipts for the month of February were £3,400, as compared with £3,391 in the corresponding month of last year.

West India and Panama Telegraph Company.—The estimated traffic receipts for the half-month ended February 28 were £2,445, as compared with £3,170 in the corresponding period of 1890.

Western and Brazilian Telegraph Company.—The receipts for the week ended February 27, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £4,895.

The Anglo-American Telegraph Company has opened branch offices at Hay's Wharf, Tooley-street, S.E., and 46, Mark-lane, E.C., for the reception of telegrams. Offices will also shortly be opened in Edinburgh, Leith, Dundee, Bradford, and Newcastle-on-Tyne.

City and South London Railway.—The receipts for last week were £753. The receipts for the previous three weeks were as follows: February 7, £702; February 14, £702; February 21, £718. The total amount received during the month was, therefore, £2,875.

Direct Spanish Telegraph Company.—The estimated receipts for the month of February were £1,953, against £2,225 in the corresponding period of last year. The Directors recommend a dividend at the rate of 10 per cent. on the preference, and at the rate of 6 per cent. per annum, together with a bonus of 1 per cent. (both tax free), on the ordinary shares, making with the previous half-year's dividend a total distribution of 7 per cent. for the year on the ordinary shares.

National Telephone Company. — This week the Directors issued £350,000 4½ per cent. debenture stock, forming part of a total amount of new debenture stock which is limited to one half of the subscribed share capital of the Company for the time being, and redeemable at the option of the Company on six months' notice at £110. The capital of the Company is £4,000,000, of which £2,494,920 has been issued. Notice has been given to pay off the existing debenture stock and bonds. The new debenture stock will then be constituted a first charge on the entire undertaking and property of the Company.

Keswick Electric Light Company.—The first report of the Directors states that the demand for light exceeds the means of supply, and they have, therefore, added another dynamo to their plant, and are going to put up a second turbine. The profit and loss account for the 11 months ending December 31st, shows a credit balance of £34. 15s. 8d., enough to pay a small dividend, but the Directors consider this amount should be held in reserve. The total number of lamps now connected with the station is 705, including one 500-c.p. arc lamp. In response to a circular, dated 13th October last, the shareholders had taken up £1,000 worth of unissued shares, leaving £1,645 still to be disposed of. The station was started on February 1st, 1890.

PROVISIONAL PATENTS, 1891.

FEBRUARY 23.

3239. **Improvements in underground conduits for conductors of electricity**. John Smith Raworth, Thomas Octavius Callender, and Charles Edmund Webber, 46, Lincoln's-inn-fields, London.

3262. **An improvement in conductors for electrical glow lamps.** Edward Alfred Gimingham, of the Edison and Swan United Electric Light Company, Limited, 28, Southampton-buildings, London.

3269. **An improvement in or connected with mechanical telephones.** Forrest William Dunlap, 53, Chancery-lane, London.

FEBRUARY 24.

3331. **Improvements in secondary or storage batteries**. Stanley Charles Cuthbert Currie, 323, High Holborn, London. (Complete specification.)

3336. **Improvements relating to welding, brazing, or otherwise joining metal strips, bars, rods, and the like by electricity, and to apparatus therefor**. Henry Harris Lake, 45, Southampton-buildings, London. (Herman Lemp and Louis M. Schmidt, United States). (Complete specification.)

3338. **Improvements in telegraphy**. Josiah Atkins Parker, 23, Southampton-buildings, London. (Complete specification.)

3349. **Improvements in electric welding apparatus.** Mark Wesley Dewey, 45, Southampton-buildings, London. (Complete specification.)

3357. **Improvements relating to the jacketing of pipes and cocks, chiefly designed for use in connection with vacuum pumps for exhausting incandescent electric lamps**. Henry Harris Lake, 45, Southampton-buildings, London. (Adolph Berrenberg, United States.) (Complete specification.)

3364. **Improvements relating to the manufacture of incandescent electric lamps**. Henry Harris Lake, 45, Southampton-buildings, London. (William Emery Nickerson and Adolph Berrenberg.) (Complete specification.)

3383. **Improvements in dynamo-electric machines.** John Augustine Kingdon, 29, Marlborough-hill, London.

FEBRUARY 25.

3398. **An improved electrical burglar* alarm** Arthur Ernest Spencer, 17, Coleman-street, London.

3404. **Improvements in switches for telephone circuits**. Charles Herbert Elliott and Ernest Frank Furtado, 10, Bush-lane, Cannon-street, London.

3417. **An improved galvanic battery**. William Henry Munns, 55, Chancery-lane, London. (George A. Smith, Canada.)

3426. **Improvements in brushes and brush holders for electric machines.** Herbert John Dowsing, 4, Queen Victoria-street, London.

3449. **Improvements in telephones.** Parnell Rabbidge, 9, Southampton-buildings, London. (Complete specification.)

3450. **Improvements in primary batteries**. Willoughby Hamilton Power, 22, Southampton-buildings, London.

3455. **Improvements in electromagnetic percussive rock drills and the like.** William A'Court Granville Birkin, 166, Fleet-street, London.

FEBRUARY 26.

3495. **Non-percussive quick-break electric switch**. Charles Mark Dorman and Reginald Arthur Smith, 24, Brasenose-street, Manchester. (Complete specification.)

3524. **Improvements in apparatus for use in the manufacture of metal tubes by electro-deposition**. Richard David Sanders, 4, South-street, Finsbury, London.

FEBRUARY 27.

3538. **Improvements in electrical contact apparatus and parts connected therewith, for automatic stop motions and analogous applications in spinning, twisting, winding, and other machines or apparatus**. John Mackie, 87, Vincent-street, Glasgow.

3553. **Improvements in conduit electric railways**. William Phillips Thompson, 6, Lord-street, Liverpool. (Ernest M. Reed, United States.)

3570. **Improvements in electro-therapeutic apparatus.** Frederick George, 11, Talbot-street, Southport.

3589. **Improvements in electric batteries**. Henry Harris Lake, 45, Southampton-buildings, London. (William B. H. Dowse, United States.) (Complete specification.)

3592. **Improvements in electric alarm apparatus.** Walter Whitehead, 33, Chancery-lane, London.

3609. **Improvements in electricity meters**. Eugen Hartmann and Wunibald Braun, 47, Lincoln's-inn-fields, London. (Complete specification).

FEBRUARY 28.

3628. **Improvements in dynamometers or force measurers.** George Richard Postlethwaite, 124, Park-road, Aston, near Birmingham.

3629. **Improvement of insulators**. Charles Dexter Barker, 76, Turnmill-street, London.

3643. **Improvements in means for holding portable electric lamps**. Frederick John Rowan and William McWhirter, 87, St. Vincent-street, Glasgow.

3650. **Improvements in electric clocks**. Leon Pope, 10, Stonefield-terrace, Barnsbury, London. (Complete specification.)

3664. **Improvements in electrical switches**. Gustav Binswanger, 71, Queen Victoria-street, London.

3673. **Improvements in electric arc lamps**. Albert Cooper Seibold, 28, Southampton-buildings, London. (Complete specification)

3675. **Improvements in apparatus for the transmission of telegraphic messages by means of direct or alternate electrical currents**. Edmund Edwards, 35, Southampton-buildings, London. (Complete specification.)

3680. **Improvements in electric lighting apparatus for gas burners**. Henry Harris Lake, 45, Southampton-buildings, London. (The Aktiebolaget Gôranssons Mekamska Verkstad Company, Limited, Sweden.)

SPECIFICATIONS PUBLISHED.

NOTES.

Telephone Clerks.—Only female operators will be employed in the Berlin telephone exchanges henceforth.

Richmond.—The Richmond Corporation appointed an Electric Lighting Committee at their last Council meeting.

Hawaii Cable.—The U.S. Navy Department is making arrangements for a survey for the proposed cable between San Francisco and Hawaii.

Dry Cell.—A new form of dry cells made by Messrs. Dalle, Molle, and Co., of Ancona, is stated to be very successful in arsenal at the Spezzia.

Lynton.—At the last meeting of the Lynton Local Board the surveyor reported that the electric lighting works had been repaired and the light was now good.

Bristol.—The Bristol Town Council, on Tuesday, resolved to expend £66,000 in establishing electric lighting in the city. The matter is fully alluded to elsewhere.

Scholarship.—The Clothworkers announce an exhibition scholarship of 50 guineas, for encouragement of proficiency in physical science, at Cambridge for July next.

Ipswich.—The alterations in the Ipswich provisional order, to omit several streets in the compulsory area, asked for by Messr. Laurence and Scott, have been refused.

Electric Traction in Austria.—The latest project is for an electric line in Austria, between Herculesbad and a station on the Vienna-Orsova Railway in the neighbourhood.

Concert.—A very high-class programme was before the Old Students last Saturday, in which stringed instruments played a prominent part. The concert was thoroughly enjoyed.

Deptford.—An interesting and important report upon the Deptford and Grosvenor stations, by Mr. Ferranti, will be found embodied in another column, under "Companies Reports."

Lifts in Madrid.—Lifts are coming into fashion at Madrid, and several hundreds will be required during the course of the year. As electricity is also in favour, the combination might also be adopted.

Paris Lighting.—The concession for lighting one of the Paris sections has been secured by Messrs. Woodhouse and Rawson, and we believe a company will be formed at once to carry out the central station.

O.S.A. Dance.—A Cinderella dance will be held by the Old Students at Westminster Town Hall on Friday, April 10th; tickets (3s. 6d. each) can be had of the secretary, 88, Queen Victoria-street.

Electric Burgling.—The latest dodge of burglars is to use the electric furnace—that is, carbon points—to soften the steel of safes. Those banks that are fitted with electric light, therefore furnish the means on the spot.

Buckingham Palace.—Even if the fog had interfered at the last Drawing Room, light would have been plenteous, for the Westminster Electric Supply Company connected their mains to the Palace on the day before the State ceremony.

Underground Telephones.—An application from the National Telephone Company to the Commissioners of Sewers to allow the laying of cables beneath the public ways in the City was laid before the last meeting and adjourned.

Franco-Belgian Telephone.—The French Director of Posts and Telegraphs states that all the telephone exchanges in the North of France (Lille, Roubaix, and Tourcoing) will be connected to the Belgian exchanges, and that a third wire is to be run between Paris and Brussels.

Electric Traction at Lyons.—In a recent sitting of the municipal authorities of Lyons, it was decided to grant a concession to the Compagnie Lyonnaise des Tramways et Chemins de Fer for a line of electric tramway running from the Gare des Dombes to the Gare de Perrache.

Leamington.—An enquiry was held on Tuesday at Leamington, by Major Marindin, inspector of the Board of Trade, respecting the applications of the Midland Electric Light Company and the Leamington Corporation for provisional orders. Evidence was taken, and the enquiry adjourned.

Acme Works Branch.—The West-end branch of the business of the Acme Electric Works has been purchased by Messrs. C. Moat and Co., and for the future it will be carried on under that title, and all the "Acme" specialities may still be obtained, together with the goods of other makers.

African Cables.—The Spanish Government is going to lay the cable at its own expense from Bonny, on the African continent, to Fernando Po, and the German Government thence to Cameroon. The Eastern Telegraph Company has sent its cable ship "Amber" to the Cameroon waters to take bearings.

Papers.—The following papers have been arranged to be read before meetings of the Old Students' Association: "Coal, Coal Mines, and Coal Mining," bv Mr. Albion T. Snell, on March 25; "Explosives," by Mr. W. M. Heller, on April 29; "Some Experiments in Magnetism," by Mr. Ernest B. Vignoles.

Chesham House, which is the finest of the ambassadorial mansions in London, is now being fitted up with the electric light, and the introduction of the new illuminant will enhance the effect of the splendid apartments of the Russian Embassy when the customary receptions take place during the season.

Ballymena.—Tenders are required for lighting Ballymena, Ireland, with gas or electricity, from August 16th, 1891, until May 16th, 1892, for the Town Commissioners. The table of lighting and other information are to be had from Mr. Henry O'Hara, Ballymena, to whom sealed tenders are to be sent by 16th inst.

Perls' Electric Signalling.—A system of electric railway signalling between engine and station is described in the *Times*, of which a working model has been on view at 62, Basinghall-street. Ten Leclanché cells are carried on each engine, and call-bells can be rung through auxiliary rails to and from the stations or signal-boxes.

City Offices.—Mr. Wilson Hartnell, M.I.M.E., is opening offices in London about the end of this month at Mansion House-chambers, 11, Queen Victoria-street, E.C., under the management of Mr. Farrar. In addition to electric lighting and power plant, he will continue the manufacture of general engineering as heretofore.

Board of Trade Unit.—The desire is apparent in Mr. Preece for a name to indicate the Board of Trade unit, and at one time he ventured on the term "bot"—a mongrel since abandoned. We have the term kilowatt for 1,000 watts, why not simply "kilowatt-hour" for 1,000 watt-hours—the Board of Trade unit, if a term is necessary.

Patent Office.—The questions recently put in the House of Commons relative to the Patent Office fees have evoked so many letters from inventors urging Mr. Leng to take up the question, that he has resolved to bring it before the House on the estimates for the Board of Trade, which has the superintendence of the Patent Office.

City Lighting.—The Streets Committee of the Commissioners of Sewers have received a letter from the Board of Trade signifying, with reference to the lighting of the City, that they were satisfied that the undertakers were in a position to discharge the duties and obligations imposed upon them by the order. This was agreed to without discussion.

Stafford.—A meeting of the Stafford Town Council was held on Tuesday. The Electric Lighting Committee reported that out of 154 circulars sent out only 27 replies had been received, and of these only two persons proposed to adopt the electric light. The committee, therefore, did not feel justified in recommending the expense of an installation at present.

Electric Flash Light Photography.—Mr. Adamson, of Glasgow, a well-known photographer, has succeeded, we hear, in obtaining excellent instantaneous group photographs by employing a series of incandescent lamps instantaneously flashed much over-incandesced. The distributed white light which results has rendered ballroom and other similar subjects very successful in a photograph.

Partnership.—Messrs. Barnett, Barnard, and Co. have taken into partnership Mr. W. R. Wynne, who has recently held responsible positions under the Westinghouse Electric Company, and the India Rubber, Gutta Percha, and Telegraph Works Company, of Silvertown. The style of the new firm will be Messrs. Barnett, Wynne, and Barnard, and their address, 92, Quayside, Newcastle-on-Tyne, as before.

St. Pancras Electrical Exhibition.—At the forthcoming electrical exhibition at the Vestry Hall, St. Pancras, the General Electric Power and Traction Company will have a very interesting show of motors driving domestic and other machinery, such as knife cleaners, washing machines, etc., as well as electric light fittings, switches, and lamps. The exhibition opens on Monday next, the 16th inst.

Telephoning to Trains.—To enable the guard of a train to give notice of breakdown from any point on the line, M. Maubogne effects communication, says the *Engineer*, between one or more of the telegraph wires and a micro-telephonic apparatus, to be carried by every train by means of a conductor terminating in a hook, to be rubbed hard against the wire to secure contact in spite of oxidation.

Garrick Theatre.—Messrs. Rashleigh, Phipps, and Dawson, electrical engineers to the Garrick Theatre, point out that the accident on the first night of the play was caused by the limelight man having been placed close to the resistances, and by his movements interfering with the proper working of the apparatus. The lighting of this theatre has been worked without a hitch of any kind for two years.

Electrical Production of Aluminium. — M. Adolphe Minet, having previously described the method of producing aluminium electrically, mentions in a note given this week in the *Moniteur Industriel*, that in the modified electrolytic process now adopted he attains the production of 32 grammes of aluminium for one horse-power hour. He uses an E.M.F. of only four volts, and the return of electric energy is given as 70 per cent.

Lea Bridge Tramways.—At the half-yearly meeting of the Lea Bridge, Leyton, and Walthamstow Tramway Company, the chairman stated that owing to the possibility of electricity or some other form of mechanical traction coming into use, the directors had not deemed it necessary to acquire a large number of horses, but had entered into an agreement with a large contractor for the supply. The line itself in many parts was in an incomplete state.

South Kensington Railway.—The London County Council are retaining Sir Benjamin Baker as witness in support of the Council's opposition to the South Kensington and Paddington Subway Bill. It is understood that, owing to the opposition from the Science and Art Department, the idea of driving the cars by electricity will be abandoned. The proposal is now to have a solid concrete cable tramway about 4ft. under the level of the Kensington Park Gardens, with or without a station in the gardens.

"The Phonogram."—We have received a copy of the first number of a monthly magazine under the above title, published at the World Building, New York, which mixes up items about the phonograph and electricity in a way that is calculated to still further foster the idea that Edison's invention is electrical. As the phonograph increases in usefulness it will no doubt require a magazine, but a musical, linguistic, reporting, and clockwork invention should not be floated in on electrical pretensions.

The British Association.—The following have been appointed to preside over the sections at the Cardiff meeting of the British Association in August next: (A) Mathematics and Physics, Prof. O. J. Lodge, F.R.S.; (B) Chemistry, Prof. Roberts-Austen, C.B., F.R.S.; (C) Geology, Prof. Rupert Jones, F.R.S.; (D) Biology, Mr. Francis Darwin, F.R.S.; (E) Geography, Mr. E. G. Ravenstein, F.R.G.S.; (F) Economics, Rev. Dr. W. Cunningham; (G) Mechanical Science, Mr. T. Forster Brown, M.I.CE.; (H) Anthropology, Prof. Max Müller.

City Subway.—In the House of Commons on Friday last, Mr. T. H. Bolton moved that clauses be inserted in the City and South London Railway Bill providing either for payment of royalty or share of earnings to the local authority, or for specially reduced fares on a specified number of workmen trains for workmen and clerks. Sir John Puleston said he was authorised by the promoters to state they were prepared to deal with the second question. The instruction to the committee was, as a whole, negatived, and similarly with the other proposed subways.

Electric Lighting in Wales.—Margam Castle, near Port Talbot, the property of Miss Talbot, is to be lighted throughout with the electric light. The contract for the work has been placed with Messrs. Drake and Gorham, whose proposal amongst several submitted for consideration was accepted. The installation will consist of a large turbine, which will suffice for the ordinary lighting requirements, and a steam engine is also to be provided for use at such times as the water power is not available. Mr. A. A. Campbell Swinton will act as consulting engineer on behalf of Miss Talbot.

Telephone Instructions.—The following striking "poem" was composed by one of the Western Counties and South Wales Telephone Company's Bristol subscribers, and placed on his telephone for general information:

"Speak softly through the telephone,
Just modulate your tongue,
A soft clear voice is better far
Than Stentor's brazen lung."

"Don't hollah through the telephone,
And rage, and shriek, and roar,
You'll hurt yourself and do no good;
Oblige by speaking lower."

Moral (!) Electricity.—A contemporary whose efforts and funds are usually supposed to be zealously devoted to the cable telegraph interests, delivered itself of a leaderette upon, of all subjects, Wesley—probably because the daily press were discoursing upon his centenary; and in the course of remarks therein, laid to the charge of the enthusiastic divine a claim for the cure of "moral" diseases by electricity, quoting as follows: "*Felons* are specially cured by drawing sparks." We wonder if our sapient contemporary ever heard of the old term for a carbuncle or whitlow as a "felon." The ascription to the good John Wesley of the cure of felony ("moral diseases") by drawing sparks is surely a little too green.

Barnet.—The Barnet Local Board at their meeting last week, discussed at great length the question of the means to be adopted for lighting the town after the expiration of the present electric lighting contract, which holds good up to the end of August. Ultimately they decided to continue the use of electricity for illuminating purposes.—At the half-yearly meeting of the Barnet Gas and Water Company, Mr. Wakefield, a shareholder, suggested that as electricity gave promise of being the lighting agent of the future, the directors might try experiments in that direction. The chairman said he could not allow risk to the shareholders; as soon as their company could pay statutory dividends they might experiment with confidence.

Personal.—Messrs. Leslie Miller and Maurice W. Woods have commenced business together as electrical engineers and contractors at 34, Gray's-inn-road, Holborn. Mr. Miller is the inventor of the Miller ammeter and voltmeter. He has been for the last 3½ years in charge of the dynamo-testing department of the Maschinenfabrik Oerlikon, near Zurich, and has also installed many of the more important electrical power transmission plants for the company. Mr. Woods has been for the last 1½ years with the Liverpool Electric Supply Company. He is one of the joint authors with Prof. Ayrton of a paper on accumulators read before the Institution of Electrical Engineers at Edinburgh, and the winner of the silver medal at South Kensington Technological Examination.

Cataphoric Medication.—A paper was read on Wednesday evening by Messrs. H. Newman Lawrence and A. Harries, M.D., on "Electricity in Relation to the Human Body." The comparative dangers to human life of continuous and alternating currents were dealt with and experiments described. The most interesting part of the paper, however, was that on the uses of electricity, during which Dr. Harries submitted a patient to the process known as "cataphoric medication," in which the drug cocaine was mechanically driven into the skin of the arm by 20 minutes' electrification by continuous current, and a needle was passed through the skin several times and hairs removed without the slightest pain being felt by the patient. Mr. W. H. Preece, F.R.S., was in the chair, and congratulated the authors.

Sensitive Galvanometer.—At the meeting of the Royal Scottish Society of Arts last week, at Edinburgh, Lord Kingsburgh, president, in the chair, Dr. R. Milne Murray described and exhibited a reflecting galvanometer for physiological work. The instrument was an astatic galvanometer of the Thomson type, with special modifications. One of these was that the mirror was placed between the two systems of needles instead of being attached to the upper system; but the principal modification was the mode of damping adopted so as to secure aperiodicity. The filament which carried the needles and the mirror had attached to its lower end a light vane, spade-shaped, which just dipped into an adjustable cup of oil, so that when the needles were deflected the capillary attraction of the oil from the vane brought the system readily to a standstill. Dr. Murray claimed for his galvanometer great sensitivity, a high figure of merit, and a remarkable degree of aperiodicity.

Bradford Tramways.—The Bradford Town Council at their meeting on Tuesday had before them the minutes of the Tramway Committee, from which it appeared that the question of steam *versus* electricity in the working of the proposed new tramway in Wakefield-road had been considered, and the committee had decided that the best motive power for the line would be electric traction on the underground system. Mr. T. C Hope (chairman of the committee), replying to questions, said that the committee had not yet ascertained the exact cost of the electric tramway. They had an approximate estimate, but were endeavouring to get the actual cost before doing anything further. The question would then arise whether anyone could be found to undertake the working of the line at the price which the committee might fix.

Concentric House Wiring.—Something very fresh and daring in the way of house wiring has been brought forward this week, and by a fire insurance official, too, we believe. This is nothing less than the bold use of bare conductors in such a manner as to do away entirely with chance of fire. Imagine one small tube of bare copper inside another, kept apart by little rings of porcelain, and there you have the very latest idea. It is maintained that if all connections are thus visible, by no chance could they be set fire to, and bare copper concentric conductors could be run in shop windows as rails for lace and trimmings with no more danger than a gas-pipe. This is something like, and the idea, once we get over our feeling of breathlessness at the suggestion, has its practical points. The inventor, it is said, is offering fifty pounds for anyone who can prove how a fire could occur or can make one with this arrangement. The rods would be tinned and screwed beforehand, and all the "wiring"—"tubing," rather—required would be to screw them together.

Kessler Magnetic Separator. — The mines of Mercadal, Spain, yield zinc ore (calamine) mixed with oxide of iron. The latter is separated by means of the Kessler electromagnetic separator. The apparatus is formed of a soft iron cylinder wound with copper wire, energised by current from a dynamo. Upon this cylinder revolve two endless chains. They are by strips of leather connected together by parallel pieces of soft iron, furnished with numerous projecting points. A bronze rail guides the ore to the chain before magnetic contact. The magnetic particles of the ore become attached to the magnetic points of the chain, and are drawn away until outside the magnetic influence of the cylinder. They then fall off into a separate compartment. A brush detaches those particles that cling more closely. The speed of rotation can be varied according to richness of the ore, and 3½ tons an hour can be treated with the employment of ¼ h.p. only. The current, 20 amperes and 20 volts, requires 2 h.p., therefore 2¼ h.p. is required for the whole apparatus. The cost of the Kessler separator is given as £90.

Central London Railway.—A long enquiry has been held this week before the Select Committee of the House of Commons, to consider the Bill for the Central London Electric Subway. The chief arrangements made are that workmen's trains should be run each way, morning and evening, at 1d. a journey, and that placards should not be displayed outside the Oxford-street stations. Sir Benjamin Baker, in the course of his examination, said that the railway was arranged to run at such a depth underground as not to interfere with the sewers, and would be constructed right through the heart of London in such a way as not to cause injury or damage to the surrounding buildings. They would require one electric horse-power to each ton weight of train; they would require 18 trains on the line to work a three-minutes' service. The trains would consist of six cars, each capable of seating 56 passengers, and on an emergency they would be able to carry 350,000 persons a day. Dr. Hopkinson, who followed, stated that he calculated the cost of the boilers, steam engines, generating dynamos, conductors in the tunnel at different places, and the locomotives necessary for hauling the trains, at £335,000.

Gordon Closed Conduit Tramways.—The interesting system of electric cars, with closed conduits, devised by Mr. J. Gordon, late German manager of the Swan Company, has been tested practically, and gives excellent preliminary results. The general idea of the system is a series of contacts, charged by means of automatic magnets in a box placed in the ground every hundred yards or so—about 16 to a mile. The preliminary trials have been made in all sorts of weather, and with very severe tests, such as flooding the whole track, 70 yards in length, with water, carting on barrow loads of earth, working in snow, fog, and so forth, through the late winter. The working pressure is 250 volts and the current about 30 amperes. The current taken in energising the magnets is ¼ ampere, and the greatest loss in running across the charged sections about one ampere—that is, in all, including resistance, say, 4 per cent. of that used. The special system ends at the contacts; any gearing or motor can be used. At present, an Immisch motor is employed with ordinary spur gearing. The system, which we have alluded to several times, now seems to be worked out in a simple and practical manner, and the tests that have been made have created a great interest in certain quarters, as showing that a practical and absolutely solid conductor rail system is applicable to street tramways. Full-sized cars are now to be built.

County Council Telephones.—The Main Drainage Committee of the London County Council report that they have had under consideration for some time past the advisability of connecting the various pumping and outfall stations and the offices of the Council at Spring-gardens by means of telephonic communication, and as they are satisfied that it would effect a large saving in time on the part of the staff, lessen labour, and be conducive to certainty and efficiency of working, they have obtained a detailed estimate from the authorities of the General Post Office and terms per annum for such telephonic communication, which estimates are as follows:

Spring-gardens to Abbey Mills, with two Gower-Bell telephones	£65	10	0
Extension from Abbey Mills to Barking outfall, with one Gower-Bell telephone and one switch	34	0	0
Extension from Abbey Mills to Isle of Dogs, with one Gower-Bell telephone	52	15	0
Spring-gardens to Grosvenor-road, Chelsea, with one Gower-Bell telephone and one switch...	31	15	0
Spring-gardens to Deptford, with one Gower-Bell telephone	62	10	0
Deptford to Crossness outfall, with one Gower-Bell telephone and one switch	72	5	0

They recommend that, subject to estimates to be submitted to the Council by the Finance Committee as required by the statute, the several lines be laid down, and be leased for seven years under the usual form of agreement.

Purchase of Railways.—The London County Council have desired to insert in the Bill for the Central London Railway a clause to provide for the ultimate purchase of the undertaking by the local authority. Mr. Pope, who, with Mr. Erskine Pollock, appeared in support of the petition, in submitting the Council's case to the committee, pointed out that the undertaking was essentially local in its character, and that from the great depth beneath the surface of the proposed line, and its class as an electric railway, with stations of a peculiar type, it was impossible that it could ever be connected with any general system of communication outside the metropolis. He pointed out that it was, in fact, a local metropolitan underground street, and never could form part of a general system; that the promoters had selected and laid down its course under land uncovered with houses and maintained open as a street at the public expense, in order to save the cost of acquiring its site; whereas, if they had designed the line to pass under houses, they would doubtless have to pay compensation to the owners and occupiers, and counsel therefore urged that this, like all similar undertakings, such as tramways and electric lighting schemes, should ultimately fall under local control, and that as railways are subject, under the Act of 1844, to purchase by the State, so this and similar undertakings, being essentially and necessarily local in their character, should be subject to regulation, and ultimately to purchase, by the local authorities. The Select Committee, however, refused to entertain the question of purchase. The clauses of the Bill are now under consideration, and the course taken with regard to them will form the subject of a future report by the Committee of the London County Council. The clause, however, which enabled the promoters to take the subsoil without compensation has been crossed out.

North Metropolitan Tramways.—The Select Committee of the House of Commons, presided over by Mr. Hanbury, evidently consider the Bill promoted by the North Metropolitan Tramways Company for the use of electricity as a motive power on lines from Clapton to Moorgate-street, and from Leytonstone to Stratford, to be an attempt, on the part of the tramway company, to override the local authorities. The application was curtly refused. The London County Council, it will be remembered, had consented to grant a license for seven years, on condition that guarantees were given for the safety of passengers and regulation of general traffic. The West Ham Corporation also assented, but sought to impose a condition that the company should agree that at any time they would, on 24 hours' notice, remove their engines and electrical plant. Mr. Pope, for the promoters of the Bill, contended that no man in his senses would contribute to the scheme if subject to such notice. Evidence for the promoters was given by Major-General Hutchinson, of the Board of Trade, who said they had electrical experts to guide them in these matters; and by Mr. Godfrey, solicitor to the company, who in cross-examination admitted that a former experiment with electric tramways, made some years ago, was a failure. The Board of Trade could at any time stop the trams in the interests of public safety. The chairman said that was all the Corporation of West Ham asked for. Mr. Adamson, general manager of the company, stated that they had 41 miles of streets, and in 1890 they carried 70,000,000 passengers. Between five and six years was the life of a tramway horse. The electrical batteries were quite isolated against coming into contact with passengers. This concluded the promoters' case, but without calling on the other side the committee decided that the preamble was not proved. The North Metropolitan will therefore either have to try electricity on other lines, or take the risk of the 24 hours' notice, or wait a year and carry the case to the Lords. The decision is a great disappointment to both tramway and electrical engineers.

Paris-London Telephone.—The most interesting electrical event that is before the public this week is undoubtedly the laying of the Paris-London telephone. For one person to be able to speak to another from London to Paris, across the sea and overland, seems nothing less than a dream of the Arabian nights, yet nothing less is expected, and, if successful, will lead to great extension of the present means of electrical communication to all parts. A most untoward happening in this connection has been the "blizzard," which so suddenly overwhelmed the country with snow and sleet this week. The "Monarch," with the telephone cable aboard, after waiting nearly a week to begin, made fast the shore end at Calais on Monday, and began paying out the telephone cable in beautiful weather on almost calm sea, when, half way across, on Tuesday the wind suddenly chopped round and blew a perfect gale from the N.W., sleet began to fall, and a furious snowstorm was soon raging. The "Monarch" had the greatest difficulty in proceeding, but struggled through and laid the cable to St. Margaret's Bay, near Dover, but was quite unable to land the shore end. The cable was therefore buoyed, and the captain of the "Monarch" was glad enough to take refuge at Deal. The land line on both sides is complete: that to Dover is taken on a new set of posts carrying double cables, a complete metallic circuit, two wires to the cable crossed continually to obviate induction; and Mr. Preece informs us that the speaking on the land line is perfect, better than any London circuit, and as good as from one room to another in the Post Office. There are 80 miles of land line to Dover, and 180 from Paris to Sandgate, where the French shore end lands. The cable itself has four thick copper wires, two of which will be used at first and the other two, if found necessary, afterwards. The total cost is estimated as about £80,000. At first four call boxes will be connected, and the respective Governments look to Stock Exchange interest to recoup them for their trouble. A West-end branch will be opened in London, and means will be taken to enable private wires to be connected. The price will be 8s., or 10f., for two minutes' conversation, with the proviso that each applicant follows his order, and no amount of money will enable one man to hold the line if another wishes to follow. The line can be used for telegraphic purposes in the night-time if not otherwise required.

Godalming.—The Godalming Town Council have adopted a scheme of electric lighting, which is estimated to cost £7,000 for plant, building, and site. The estimated working expenses are £900 per annum, and the revenue £1,250, leaving a balance of profit of £350. The co-operation of Charterhouse has been solicited, but the authorities do not feel in a position to join at present. The Council, therefore, have considered the scheme for town lighting only, the main features of which are as follows: The central station plant to consist of two boilers, 52 h.p. each, two 65-h.p. engines, two arc light dynamos, three incandescent ditto, and all switches and sundries. The cable mains to be laid in subways, the street lamps to be 35 arcs of 300 c.p. each. Provision for private lights to be 800 incandescent lamps of 16 c.p. Careful estimates of the above have been obtained amounting to £5,565. A site has been offered for the central station which the engineers report on as being most favourably situate for the purpose, especially if the lighting is extended at any future time to the outside district. One or two other sites are obtainable. It is approximately estimated the site and necessary buildings would cost from £1,200 to £1,500, making the total outlay for plant, site, and buildings nearly £7,000. The working expenses have been carefully estimated as follows: Coal, £170; labour, £200; carbons and sundry, £100; depreciation, £140; 4 per cent. on capital, £280; total, £890. The yearly revenue: £280 present cost of borough lighting; £962. 10s., say 700 lamps taken up at average cost of 27s. 6d.; total, £1,242. 10s. The balance of profit shown by this statement amounts to £352. 10s. per annum. This return is based on the condition of 700 lights being taken up at an average price of 27s. 6d. This price of 27s. 6d. per lamp is stated as about equal to half the cost of a gas burner using 7ft. per hour, and burning the same length of time. It is probable that the plant proposed would supply actually 1,000 lights if required. The committee are advised that the scheme is as perfect as it can be made, that all the machinery is duplicated to avoid the possibility of breaking down, and that the whole would be of the very best manufacture. The central station would also be so arranged as to admit of easy further extensions from time to time. The town clerk was instructed to send the report to the Local Government Board, and request them to hold an enquiry.

Repairs of Incandescent Lamps.—The cost of maintenance of electric installations is materially enhanced by the breakage of incandescent lamps before their time, and attempts have been made to render the repair of broken filaments a practical trade. How far this will become general or profitable will depend upon the cost price at which the glow lamps are retailed as compared with the cost of repairing, but at the present price used up globes should repay repair, and we believe that in this country Messrs. Shippey carried on a somewhat extensive trade in this direction. We see that the process of repairing lamps quickly and economically adopted and developed by a French engineer, who has for several years devoted considerable time to this problem, is described in the French technical journals as a really practical method. The lamp after being repaired is reconstituted without change of form, and the life of the repaired lamp is at least equal to the original. The process gone through is as follows: The glass-blower takes the lamp and makes at the top a hole large enough to admit a new filament. The lamp thus opened is passed to a girl, who, by means of special nippers, cuts the broken filament, which she removes, being careful to leave on each platinum support about one millimetre of filament. A second girl takes the prepared lamp and places it in a socket to which current is led; she then fills the bulb with a hydro-carbon liquid, and introduces a new filament previously standardised. By the aid of a pair of special pliers she touches the filament to one of the ends left and turns on the current. The liquid becomes decomposed into hydrogen, which rises through the liquid, and into solid carbon, which is deposited upon the joint, firmly connecting the filaments together. The same is then done for the other end of the new filament. The next process is the cleaning of the glass bulb, which, it is stated, becomes, if anything, cleaner than the new lamps. The glass-blower then takes the lamp again, attaches a tube of glass to the opening made, and the repaired lamp is then exhausted, the process of exhaustion taking three-quarters of an hour, each pump carrying five lamps. The bulb is then closed in the usual manner. The different operations described are performed very rapidly, and form an elegant and practical process, and may be repeated many times. For "Sunbeam" lamps the process is easier still on account of the size, and may be performed either to replace filaments or to clean the bulb. The best proof, says *L'Electricien*, that the process of M. Pauthonnier is really commercially practical is that it is to be introduced on an extensive scale into the United States at once.

UNDERGROUND MAINS.—V.

THE BROOKS SYSTEM.

(Continued from page 242.)

Messrs. Johnson and Phillips have made several very severe tests of the system at their works, and continue to have the strongest convictions that it is a reliable and efficient one. A line of 700ft. in length was laid down at Charlton, under the supervision of Mr. David Brooks, who visited this country in order to convey to Messrs. Johnson and Phillips his past experiences in the carrying out of his method. The cable consisted of seven No. 18 wires, each wire double cotton-covered, and braided with cotton twisted into a cable and braided over all; this length of cable was drawn into a 1in. iron pipe, and the whole system filled with hot fluid dielectric. The line has now been *down for about two years*, and it is to-day as perfect *as when first completed. During the interval* many searching tests of the line have been made, and on many occasions six of the wires have been grouped into two circuits of three wires each, and a Kapp alternator giving 2,000 volts has been connected to one end of the line, and a group of incandescent lamps lighted at the other end for several hours continuously. Measurements made before and after the run showed no fall in the insulation, and it must be remembered that in this case a pressure of 2,000 volts was exerted between wires whose covering of cotton did not exceed $\frac{1}{16}$in., intimately twisted together. Some details of the tests made at the time upon this line were given in our issue of September 20, 1889.

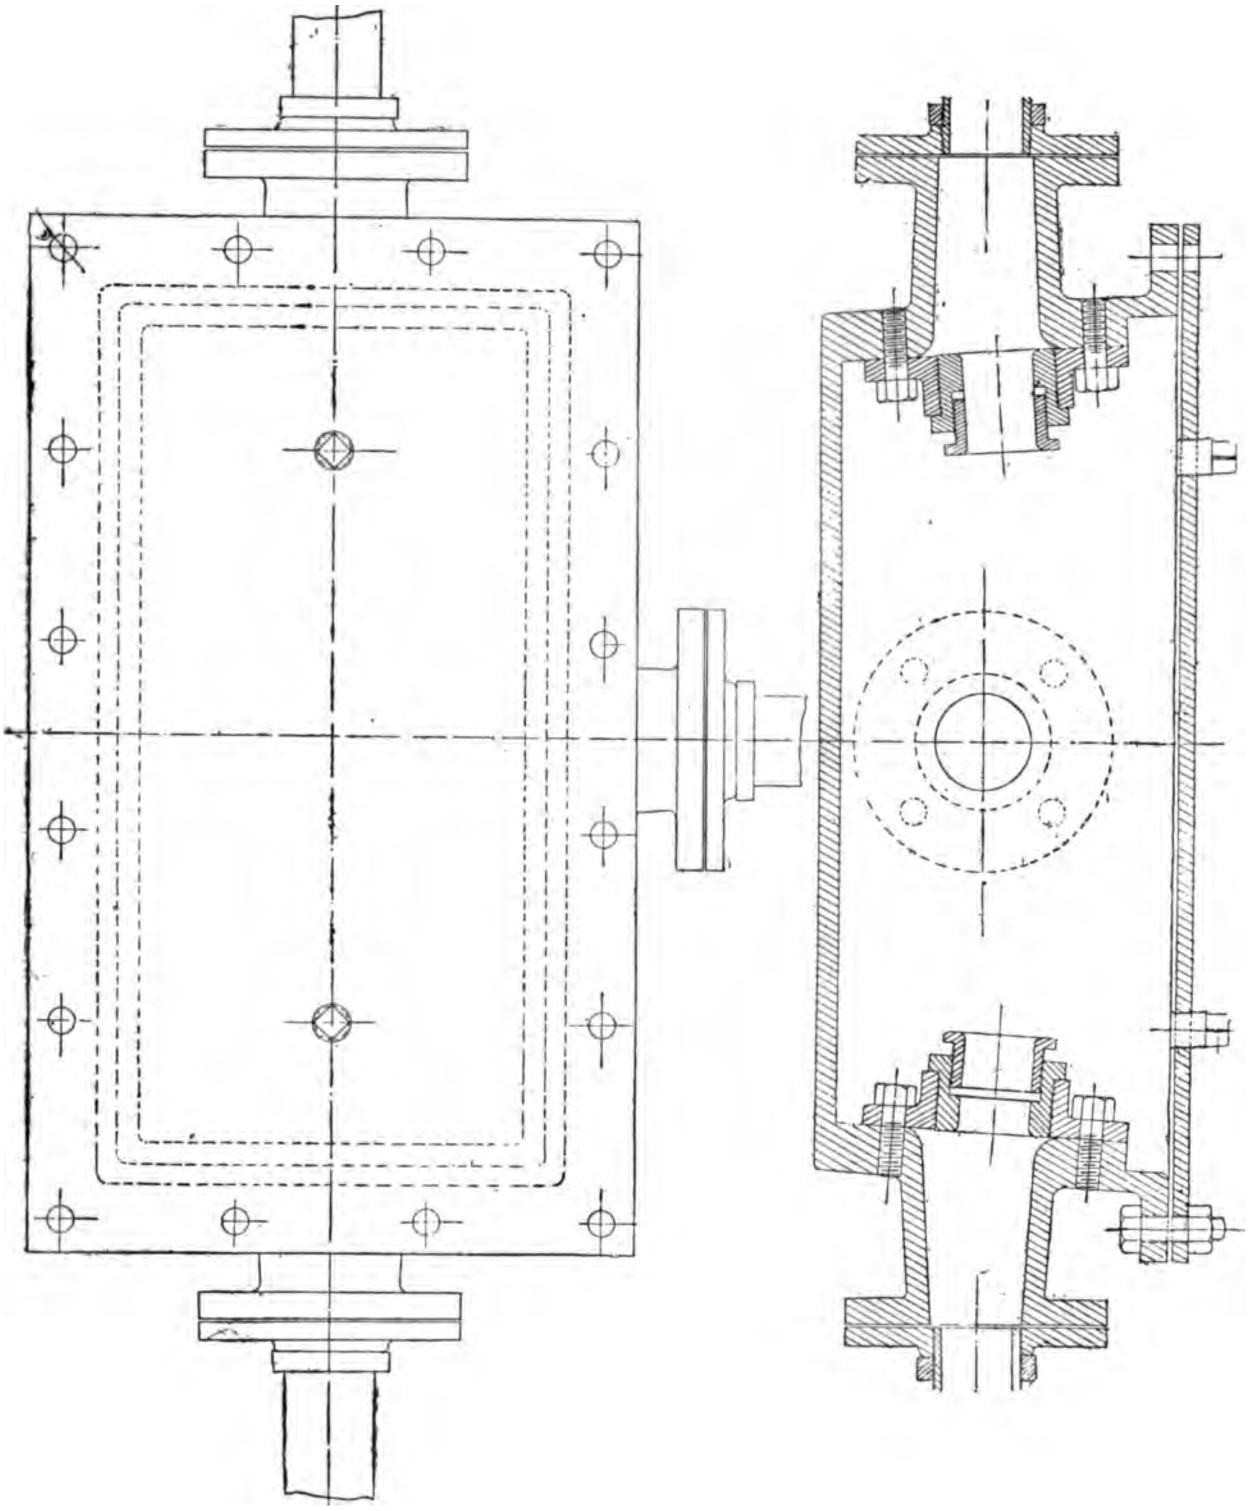

Fig. 7.—Junction Box, Brooks' System. Plan and Section.

Another line was afterwards put down at Charlton, one-tenth of a mile in length, containing two cables, each of $^7/_{14}$ wires, braided with a fibre to a diameter of about $\frac{5}{8}$in. These were drawn into the pipe in two lengths, and the whole system filled with dielectric. This line has frequently had, under the direction of Mr. Kapp, a pressure of 14,000 volts for five hours at a time upon it. The test was made by transforming up from a 2,000-volt Kapp alternator to 14,000 volts, and at the other end transforming down again to 2,000 volts, and then lighting 20 100-volt incandescent lamps in series to full brightness. This potential gave a sparking distance between points of $\frac{13}{16}$in. at the dynamo end of the line, and at the far end a somewhat greater distance. The line tested immediately before and after the run showed no change in the insulation value.

A recent communication from America dealing with this system gives particulars of underground mains with liquid insulation laid for the Heisler Electric Company, which gives entire satisfaction, having been in constant use for nearly a year in circuits using very high E.M.F., varying from 2,400 volts up to 4,000 volts, and the remarkable feature is the fact that the insulation resistance is higher to-day that when first installed. Repeated efforts have been made to break down the insulation by subjecting it to various and unusual strains, such as suddenly breaking the circuit when the dynamo was running at its greatest speed, and also subjecting lengths of the line to a static charge equal to 140,000 volts. They stood perfectly, though this test is sufficient to break through every other kind of insulation, however perfect it may appear by galvanometrical tests.

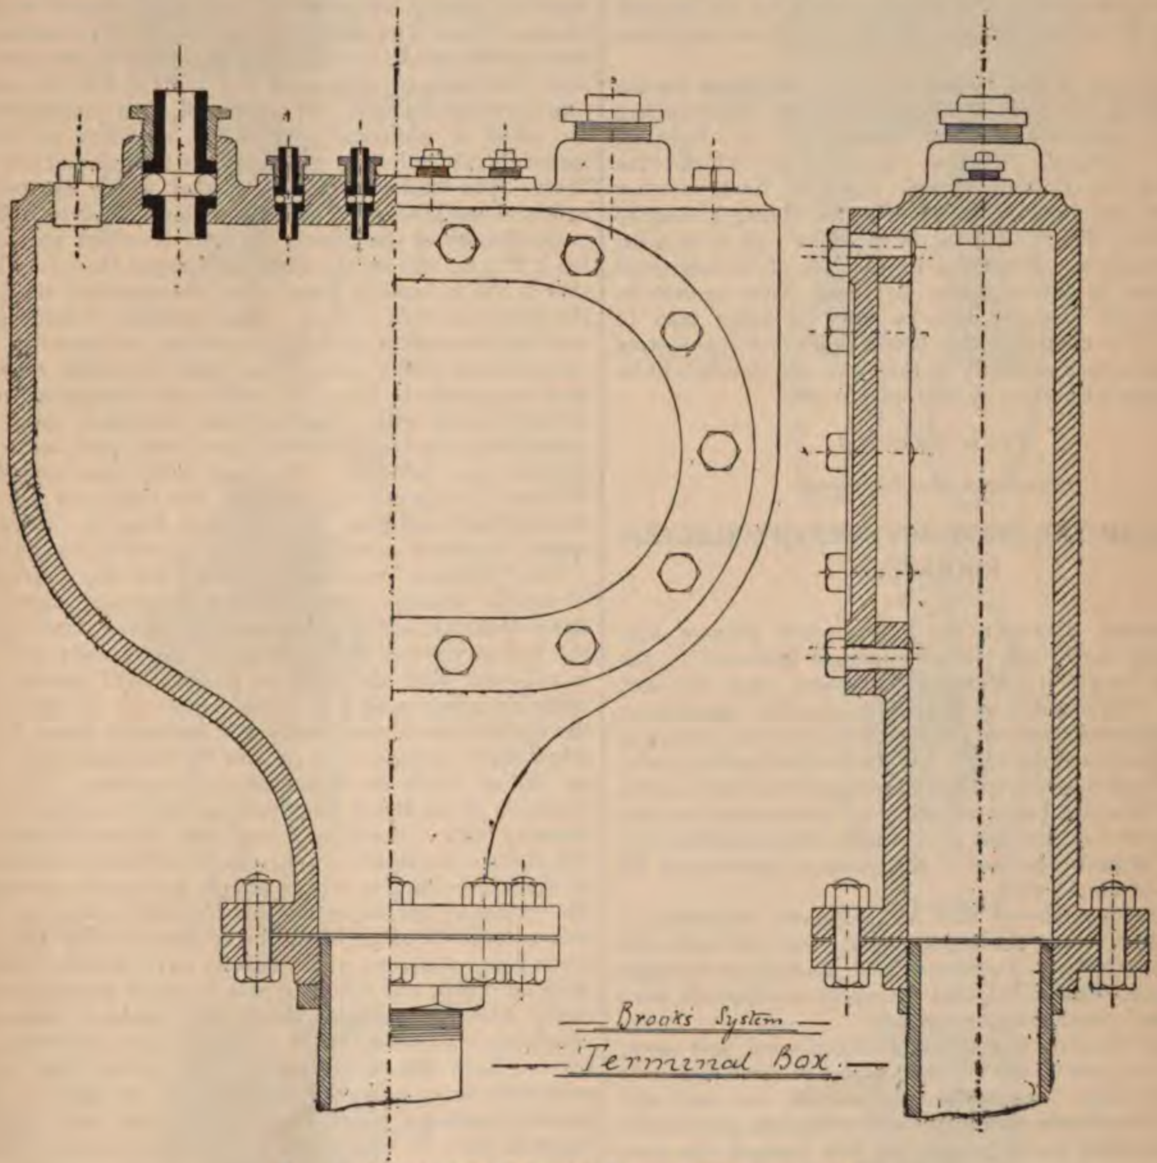

Fig. 8.—Terminal Box, Brook's System. Elevation and Section.

In England the Brooks system has been used for a short length in the Keswick central station system. Two single No. 14 copper wires, twice braided with jute, and enclosed in an iron pipe with liquid insulation, are used for connecting the church with the overhead high-tension wires. The Brooks main goes under the graveyard to obviate the use of overhead mains. The wires have carried the full pressure of 2,000 volts for a period of over 14 months.

They have also been used on low-tension work in a large private installation for Lord Windsor, where 500 yards of four strands of $^{37}/_{13}$ are worked two each in parallel as main conductors under the grounds from the dynamo-room to the house, to entirely do away with the necessity for overhead wires. Various other private installations have adopted the system. Besides this, the system has been for many years in use on certain railways in England for telegraph wires with very marked success.

Abroad, Messrs. Johnson and Phillips have just furnished the Hong Kong Electric Light Company with 2,000ft. of the Brooks main for high-tension work in connection with the arc lights for public lighting. These mains are to go under the streets to work with a pressure of 2,000 volts The plant is now in process of erection.

Our illustrations give the details, at quarter full size, of the junction-box and terminal-box shown in perspective last week. The cuts are reproduced from the working drawings and practically explain themselves. Fig. 7 shows details ot the junction-box which is laid under the street level. The exits or glands for the cable are arranged so that they can be packed and can also be plugged inside to prevent oil escaping, if the box is required to be left at any part of the progress of the work. In laying, the cables are drawn through from point to point at these boxes, into which the liquid insulation is afterwards poured, and the lid securely fastened down.

Fig. 8 shows the terminal-box, which stands directly under the switchboard at the generating or at the receiving end of the line. Glands are provided when required in the case shown for two cables and pilot wires.

In this system it is seen that there is no space left for the accumulation of explosive gases, or gases injurious to the dielectric, as might be the case where a solid dielectric is used in conduits or iron pipes; and Messrs. Johnson and Phillips themselves believe that the only other system that could compare on the score of efficiency and permanency with the Brooks mains, is that in which the cables highly insulated with indiarubber or guttapercha are drawn into iron pipes kept full of water.

Experience in America for a period of at least 10 years has already demonstrated that, in the Brooks telegraphic and telephonic mains, the cost per wire in a cable of many conductors is less than the cost per wire insulated with guttapercha or indiarubber, even including the additional charge of conduit-pipe and boxes, or other device.

It has also been abundantly proved at Charlton that mains for the distribution of electric light and power will stand the severest tests that are ever likely to be required with even far higher voltages than at present are anywhere employed.

Probably one of the largest fields of usefulness for the Brooks mains will be in connection with the high-pressure three-wire alternate current distribution for lighting, and for alternate current motors, of which the installation to transmit several hundred horse-power a distance of 12½ miles at 25,000 volts, now being erected at the Oerlikon Works, Zurich, is the first and most noteworthy example. Examples of the use of underground transmission in towns where overhead wires cannot be employed will probably not be long in being seen in practice. The details of the Brooks mains for this system have already been carefully worked out, and details will be given of this interesting system next week.

(To be continued.)

LAUNCH OF THE FIRST GOVERNMENT ELECTRIC PINNACE.

On Tuesday afternoon the first electric pinnace constructed for the British Government was launched at the Chiswick works of Messrs. Woodhouse and Rawson, Limited. The event is of somewhat peculiar importance, as though electric boats of larger size have been running for some years and are fairly familiar to the boating public, yet the official and Governmental recognition of the electric launch as of actual practical utility for transport of soldiers and other similar purposes in our naval dockyards has only just been given in the case of the pinnace constructed by Woodhouse and Rawson.

It will be remembered that Mr. Sargeant, who designed for another company the largest electric boat yet made, has lately joined Messrs. Woodhouse and Rawson as manager of the launch department, and the works at Chiswick have already been considerably extended.

The late terrible weather, with fierce wind and snow, did not conduce to the pleasant aspect of road and river that the few days before seemed to promise, and cold and bleak was the outside appearance of the Thames, while inside the boat-building works (which are just beneath the iron railway bridge at Putney) Press representatives, engineers, members of Woodhouse and Rawson, boating-men, and the workmen and launch-builders crowded round the vessel whose first dip was to take place.

The first Government electric pinnace is a very neat, well and solidly built open boat, 48ft. 6in. long by 8ft. 9in. beam, constructed of mahogany with teak fittings. She is built to carry 40 soldiers, and nearly the whole of the inner space is open, with seats around, under which the storage cells are placed, the total draught being 2ft. 3in. when loaded. All machinery is out of sight, nothing save the double-bladed screw and the switch-handle being visible. The boat is fitted with 70 cells; those now used are E.P.S., but it is intended to fit her with a new type of cell—the "Epstein"—on which Mr. Epstein, accumulator manager for Woodhouse and Rawson, has been at work for some years, with, it is stated, extremely successful results. The new cells are of corrugated or grooved solid lead, *chemico-electrically* treated, and, we are told, of about one quarter the size and 25 per cent. lighter than the ordinary lead cells. If this is so, no doubt further particulars and tests will be forthcoming.

For the first trial, however, the ordinary storage cells are used; there are 70 cells of 19 plates each. The E.M.F. is therefore 140 volts. The motor is of a special make by Woodhouse and Rawson, of high efficiency, and made to sit very low on its bearings. It gives 5½ h.p. to 6 h.p. at full speed, the screw being 22in. across, working at 750 revolutions. The switch is arranged to allow full speed and half speed respectively ahead or astern. The charging current for the cells is 35-40 amperes during six hours, and the discharge at full speed 30-32 amperes, and at half speed 19 amperes. The specified speed is eight knots an hour on the measured mile under full load, or about 10 miles an hour. The boat can run 10 to 12 hours, and can go from her present moorings to Chatham Dockyard with one charge. There is no need of any engine driver or mechanic—anyone who can be trusted with an ordinary boat can run her. For cases of emergency she is fitted with two masts, two balanced lug sails, and a stay sail, thus enabling her to be sailed or electrically propelled according to circumstances. She will turn with head up to the wind and stay there. The total weight is 4¾ tons, of which 2½ tons are cells and machinery. The price is about £550 to £600.

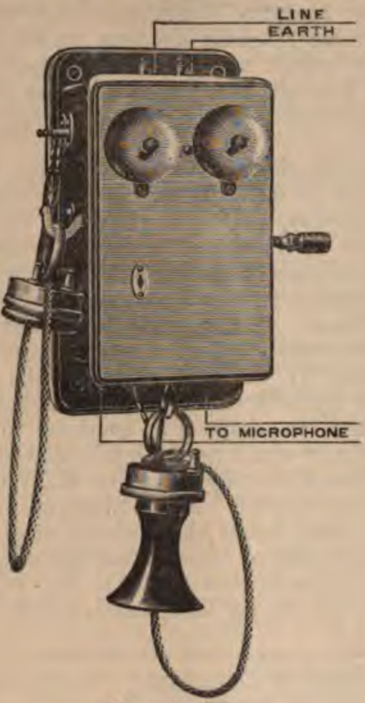
On the day of the launch, the time of which was settled for 1.30 p.m., the strong wind had delayed the tide so much that it was at least an hour after the specified time that the water rose high enough. The crunching of screw-jacks, and the heavings of crowded shoulders, accompanied with lusty cheers, finally moved the boat down the slips, and sent her splashing into the water—Mr. Sargeant, on the forward deck, with weatherbeaten furrowed cheek and peaked cap, vigorously waving the Union Jack, and cheering his men forward. The boat, which was named the "Electric," rode gallantly out into the river, and was then brought back and filled with visitors desiring to try her speed; a short trip was then taken up and down the river.

The "Electric" was built primarily for the conveyance of troops between Chatham and Sheerness, along the River Medway, and is of almost exactly the same type as the ordinary Government steam pinnace already used. It is expected that the electric pinnace will present considerable advantages over those now in use, as not only is the electric boat always ready at a moment's notice, but its actual carrying capacity is greater for the same size, while no skilled hands or engineers are necessary. It is the intention of the Royal Engineers to make a series of exhaustive tests of the type of boat, and Messrs. Woodhouse and Rawson are erecting a charging installation at Chatham, at which the charging will be simple and purely automatic. The company are expecting considerable orders for this class of boat for employment in connection with the large ocean-going steamers, which already have electric installations on board, and would be able to make great use of an easily handled pinnace, either for landing passengers, obtaining provisions, or in case of "man overboard" at sea to have the boat ready and power up at a moment's notice. Messrs. Woodhouse and Rawson have recently opened a second boat-building yard, and a third is expected soon to be opened in the same place. Indeed, their work in boat or launch building, not necessarily electrical, is rapidly extending, and special plant for iron and steel boats is being put down. We were shown a large steel steamboat, 56ft. long, for the Mexican Government, ready for launching. Two Government boats for the Thames have just been ordered, and others are expected shortly to be launched. Besides this, a third electric boat for the celebrated Mr. Pears is in hand, and other electric boats for pleasure or business purposes, an interesting one being the "Delta," an electric launch, built entirely of Delta metal, which will be at Henley this year.

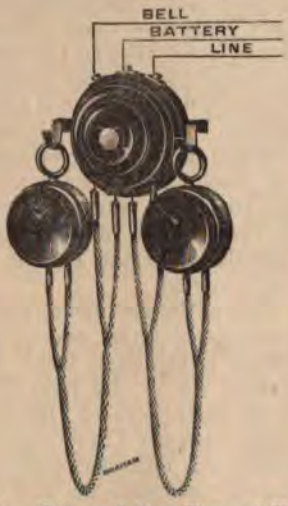
GENERAL ELECTRIC TELEPHONES.

The impetus to telephonic extension that has resulted from the expiry of the Bell patent is continually increasing, and we illustrate to-day a few specimen forms of the magneto instrument that is being introduced by the General

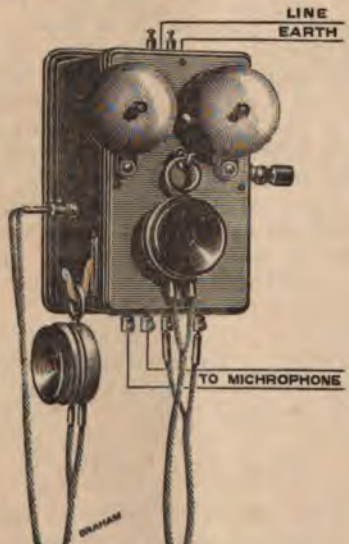
Electric Company. The telephones are neat and handsomely finished, and from actual experience we can testify that the enunciation is clear and distinct through them.



Magneto Set.



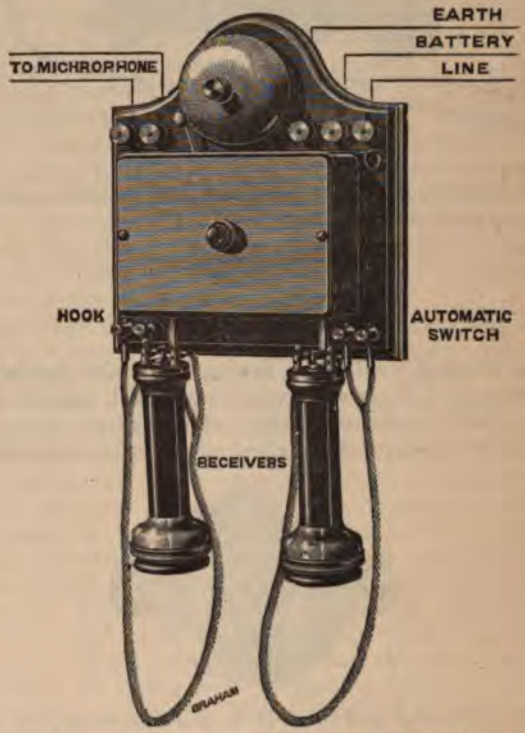
Battery Sets. Bell and Box Type of Telephone.



Magneto Set. Box Telephones.

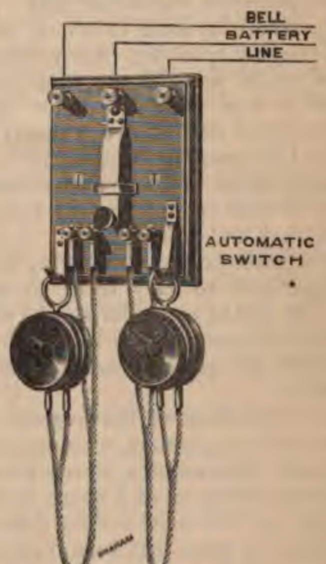
The idea of the introduction of the types shown is the supply of the very wide want for small sets for house and office use, which must arise all over the land as soon as the public realise that they can obtain a telephone set for practically a few shillings. There is no attempt to deal with public exchanges.

The illustrations show various types: the ordinary well-known shape of Bell telephone, or the more modern box or watch case telephone, and these either arranged with a battery and bell or with magneto alarm. Some are also provided with full contacts for a microphone to be connected thereto later on, if desired. Various arrangements are made which explain themselves in the illustrations. One



Battery Sets. Bell and Box Type of Telephone.

Box Telephone.



Automatic Switch.

neat connection is that shown in the automatic switch, where two metal plates are fastened to the hook and the connection is made across simply by the metal ring handle of the telephone. These telephone sets should be well and largely patronised.

Bell Telephone.

CURRENT INDEX.

The frequently-called-for device, illustrated herewith—Hartmann and Braun's current index, which will show at a glance (when in circuit) what accumulators are doing, whether charging or discharging—is a regular speciality of Messrs. O. Berend and Co. It is a well-constructed little piece of apparatus, of high finish and workmanship, and should prove useful on every installation which includes accumulators, as is the case with most separate house installations of present practice.

NOTES ON THE ELECTRIC RAILWAY: HISTORICAL, STATISTICAL, AND TECHNICAL.*

BY FRANKLIN LEONARD POPE.

(Concluded from page 211.*)*

What is termed the commercial efficiency of an electric railway is the ratio between the power generated by the steam engine and that exerted upon the car wheels. We may call the weight of the car body and truck, plus the full load of passengers, the useful load.

The best authorities seem to concur in the opinion that it requires, roughly speaking, nearly twice as much power per unit of useful work done, with the storage battery system, that it does with the direct distribution system. The dead weight of the battery is nearly equal to that of a paving load of 30 passengers, and this load must be transported whether there are any passengers or not. The increased weight adds to the cost of renewals and repairs, both of the track and of the cars.

The cost of horse power for drawing cars has been found by long experience to vary from 10 to 11 cents per car per mile. The cost of power for the 10 storage battery cars on the Madison-avenue line in New York is said to figure out 10·6 cents per car per mile, practically the same as horse power.

A careful computation of the average cost of power by the direct distribution system, on a considerable number of different lines in this country, shows that the cost for coal, attendance, real estate, oil and waste, repairs of machinery and line, foots up 5·09 cents per car per mile.

You will bear in mind that I am now speaking solely of the cost of power; the greater part of the expenses of any street railway company remain substantially unchanged whatever kind of power is used.

We often hear people say, "what difference does it make to us how much the power costs the railroad company? We pay five cents per trip, no more, no less." It is only a question of increasing or diminishing the profits of the corporation. But this is a very short-sighted way to look at the question. Increased economy in conducting transportation means more frequent and less crowded cars, greater speed, more branch lines, and better accommodations in every way. You still have to pay your five cents, it is true, but you must remember that you get a great deal more for your money.

I once had occasion to study this whole question very minutely. In the fall of 1886, when the West End Street Railway Company, of Boston, was first organised, I was commissioned by President Whitney to make for him a careful investigation of the subject of electric propulsion, which he desired to apply to the entire street railway system of Boston. It was a gigantic proposition, for at that date there was hardly a dozen electric street cars running in this country. I was told by him at the outset that I must confine my researches to conduit and storage systems; that anything in the shape of an overhead line was out of the question, and would never be tolerated in Boston for a moment. I submitted my report to Mr. Whitney on the 30th day of April, 1887. At that time no experience had been gained which would enable me to compute accurately the cost of operation of the different systems, but the final result of my estimate then given to Mr. Whitney, of the cost of power per car per mile, was as follows:

Horse power	11·07	cents.
Electric storage system	7·34	,,
Electric underground distribution	6·02	,,
Electric overhead distribution	3·28	,,

It will be seen that these figures estimated the cost of the storage system as a little over twice that of the overhead system. Experience has confirmed the substantial accuracy of my original estimate in respect to relative cost. The absolute cost for all electric systems is considerably greater than was anticipated. This is partly due to the item of repairs for the electric motor and gearing, which are found to be subject to much greater wear and tear than experience had given reason to anticipate, and partly to the great increase in the number of passengers per car mile, caused by the popularity of the electric cars, which adds greatly to the loads carried.

Mr. Whitney then authorised me to construct an electric car operated by storage batteries, and to give the practicability of the scheme a thorough test. This pioneer car, the very first electric car of the West End Company, was put in service in the early part of October, 1887, and was run for some time between Cambridge and Boston. A careful series of tests and measurements showed the cost of operation to be about the same as that of a horse car of equal capacity. The West End Company continued to experiment, putting down, the next year, an expensive conduit line on Boylson-street, in Boston, and an overhead line on the extension of Beacon-street, in Brookline. The comparative results of the practical trial of the three systems was so favourable to the overhead line that the objections of the citizens of Boston were gradually overcome, and at length overhead wires were permitted to be placed in the streets of the city proper.

Finally, I propose to consider the question whether there are any valid reasons why the public should object to the introduction of electric railways, or why the municipal authorities should hesitate to grant the necessary franchises. Are electric railways dangerous?

With a view of getting at the actual facts in the case, the *Boston Advertiser*, a few months ago, sent out a circular letter asking information from every city in which electric railways are in actual operation, from Portland, Me., to Galveston, Tex. It was asked what system was used in each place, whether there had ever been loss of life or injury from the wires, whether there was any serious objection on the part of the public to overhead wires, and what was the general opinion in the locality as to the effect of the introduction of electricity upon the street railway service? Replies were published from 64 cities and towns. All but four of them were favourable. Not one solitary instance of accident or serious injury from electric currents was reported. One of the objecting places was Newport, R. I., where it seems the "upper ten" strenuously opposed the introduction of anything that would popularise riding on the streets.

---

* *Paper read before the New York Electric* Club, Jan. 22.

An extraordinary amount of nonsense has been printed and talked in respect to the alleged dangers of both electric light and railway wires. The public have been needlessly alarmed by the exaggerated statements of interested parties; but, nevertheless, the danger is so small, as a matter of fact, that the actual figures are almost astonishing. Most of the accidents which have been reported occurred in New York City. Yet the statistics show that in 1889, out of 1,467 deaths in New York City, by accidents of various sorts, only *nine* were due to electricity, a considerably less number than were killed by being run over by horse cars. Not a single death was recorded in Boston, although there are perhaps more wires there in proportion to the population than in New York. There are in the six New England States nearly 140 arc light stations, burning over 20,000 arc lamps and distributing 30,000 horse-power of electricity through the streets of the principal cities and towns. During the last 10 years, as far as I can ascertain, there have been but five deaths from electricity; four of these were employés of the lighting companies, and one was a careless boy who climbed upon a shed and took hold of a wire. During the same 10 years the steam railroads of New England have killed 2,349 employés and 2,902 other persons; 5,241 against 5. Not only is electrical power far less dangerous than the same quantity of power used in other industries, but it is relatively safer, as the few accidents that do occur are among the employés. These remarks refer to electric wires in general. Now as to electric railway wires:

I believe that it is an incontestable fact that not one single man, woman, or child has ever been killed or even seriously injured by a 500-volt current, which is the highest pressure ever permitted upon electric railway wires. Every alleged case of accident by railway wires has, upon investigation, proved to be either without foundation, or to have been caused by an electric light current. When we consider that shocks have been experienced by men, women, and children; persons of all ages and all sorts of physical condition, sometimes for a period of several minutes, experience seems to warrant the positive assertion that the electric railway current is not dangerous to human life, and that we may dismiss that question from further consideration.

Many person are alarmed at the vivid flashes of light which are often seen at night beneath the wheels of an electric car, and at the point of contact of the trolley wheel with the overhead wire, and are under the impression that they must indicate a very dangerous electric pressure. Such, however, is not the case. In an electroplating establishment at Ansonia, Conn., I once saw a workman accidentally set a tin pail filled with water upon a pair of electric conductors near the dynamo. The pail instantly disappeared, being not merely melted, but being converted into metallic vapour, with a terrific flash which illuminated the whole building with a dazzling and instantaneous radiance; yet the current which produced this startling phenomenon was of such low pressure that it was impossible to detect its presence by the sense of touch, even by applying the hands directly to the conductors.

The average speed of the horse car is about six miles per hour. The question is sometimes asked, How fast may electric cars be safely run in a city street? One fact within my own knowledge will go far to answer this question. There is a heavily travelled street in Pittsburgh only 36ft. wide, containing a double-track cable road, which leaves not more than 9ft. space on each side. At first the cable cars were run at the rate of seven miles per hour; afterwards the speed was increased to 9½ miles per hour. The records show that there are not so many accidents under the present arrangement as there were before. Pedestrians and drivers are more careful and take fewer chances. The schedule rate of the electric cars in Cleveland is nine miles per hour, and in some parts of Boston as high as 12. The value of an electric railway to the public is largely determined by its speed, but the economical aspect of the question is equally important. If we make six miles per hour with horses, and nine with electricity, each car does 50 per cent. more work without increased expense for conductors' and drivers' wages, which is an important item. Another economical feature due to the use of electricity is the ability to haul one, or even two, tow cars without loss of schedule time on special occasions when the traffic is unusually great.

Nothing is more astonishing than the capacity of the electric cars to make their schedule time in the face of the heavy storms of a New England winter. It is a common sight to see an electric car running, apparently with perfect ease, up a heavy grade through snow a foot deep, pushing or pulling cars loaded to their utmost capacity.

The total number of electric cars now running in this country is probably between 2,500 and 3,000. Of the whole number, I presume not more than 30 or 40 are operated by storage batteries. The fact that the overhead system, though introduced at a later period than either the storage system or the underground distribution system, has so far surpassed them both, goes far to show that as yet it is the only system which has been able to meet the various exacting requirements of our street railway service.

I regret that the necessary limitation of time does not permit me to mention more at length the work of other American inventors, to whom the development of the electric railway is largely indebted. Among them are Charles J. Van Depoele, of Chicago, now with the Thomson-Houston Company, at Lynn, who exhibited a car in operation in Chicago, in 1883; Leo Daft, whose motor drew a full-sized passenger car over the Mt. MacGregor railway at Sarotaga, in 1883; and especially Lieut. Frank J. Sprague, who designed, carried out, and completed the first installation of electric railroading on a large scale in the world, in Richmond, Va., in 1888. This was a road 12 miles in length, with a great number of curves, a bad track, numerous grades of 10 per cent. and over, and an equipment of 40 motor cars. Labouring under enormous difficulties and drawbacks, Lieut. Sprague succeeded, by the completion and operation of this plant, in establishing beyond peradventure the future supremacy of the electric street railway, and many of the characteristic features at that time designed and introduced by him have practically become standards in the modern system, and are found in nearly everyone of the thousands of cars now in service.

The limits of time compel me to content myself with the briefest possible reference to the most important development of electrical transportation which has yet come before the public—the electric underground railway. This undertaking having been placed in the hands of electrical engineers whose competency cannot be questioned, and backed by ample capital, has proved in London a phenomenal success. We are now assured that a syndicate of the most prominent capitalists of New York have undertaken to establish a system of transportation upon the same plan, consisting of a network of tunnels at a depth of 100ft. beneath the surface, and connecting all important points, not only in the city itself, but in the adjacent sections of Long Island and New Jersey. In such a system it necessarily follows that the train must be run by electricity to the exclusion of any other power.

Every thoughtful person realises that something must be done at once, not only to relieve the congestion of traffic which already exists in the streets of New York, but to provide for the enormous yearly increase which must be taken into the account. Statistics show that the traffic of the horse cars and elevated lines in New York has increased 46 per cent. within the five years from 1884 to 1889. A careful estimate which has recently been made of the movement of passengers in and about New York during the year 1890 gives the following amazing result:

New York City (surface and elevated roads)...	400,000,000
Brooklyn Bridge	38,000,000
Long Island ferries	90,000,000
Staten Island and New Jersey ferries............	85,000,000
Total	613,000,000

If the profit derived from carrying these passengers amounts to only one cent each per trip it nevertheless figures up to the snug little sum of 6,000,000dols. per annum, which makes a very comfortable dividend upon a capital of 100,000,000dols. Such a system would admit of the running of solid trains at very short intervals through the city, to and from all points in the suburbs, in every direction, and I venture here and now to predict that within the next 20 years, if not the next 10 years, electrical underground transportation will be brought to such a state of perfection that a passenger entering one of the central stations of New York may be deposited at his home station at any point within a radius of 10 miles in 15 minutes time and at a fare of five cents. And the magnificent result is to be the contribution to the convenience and the prosperity of the public of the electrical engineer.

LITERATURE.

"**Intensity Coils: How made and how used.**" By DYER. Sixteenth Edition. London: Perkin, Son, and Rayment.

A book that has reached a sixteenth edition, and which has been before the world for many years, must contain information that is wanted. The Ruhmkorff coil has become one of the most interesting pieces of apparatus in electrical engineering in its comparatively recent development, known as the transformer. This book shows very clearly the historical views held about the coil, and from the amateur constructor's point of view is most valuable, in that it explains clearly how to make and how to use a coil. A great many lecture experiments are described. Although the preface of this edition states that "opportunity has been taken to make some additions" to the book, it may be pointed out that the portion devoted to dynamos is hardly up to date, and that "seeing by electricity" is at the present time quite in the clouds. We would suggest that future editions should be restricted to the dealing with coils and transformers.

UNDERGROUND CABLES.*

BY STUART A. RUSSELL.

The subject of this lecture, as announced to you in the programme, is one that covers a great deal of ground, and were I to attempt to treat it in its widest sense, I am afraid it would require a much longer time than could possibly be given to it in one evening. I propose, therefore, to confine my remarks more especially to the subject of underground insulated conductors, as used for the distribution of electrical energy from central stations.

As you all know, the insulated conductor is the connecting link in a system of electrical transmission between the generator of the current and the apparatus where the electrical energy is to be converted into other energy, whether of motion, light, heat, or chemical action. It consists always of two parts whose functions are for the one to offer as little resistance as possible to the passage of the current along a certain defined path, and for the other to offer as high a resistance as possible to the escape of the current from that path by any other way.

All known substances are to a greater or less degree conductors of electricity, but it is usual to speak of them as divided into two distinct classes—those offering little resistance being called conductors, and those offering a high resistance being called insulators. Amongst conductors are classed all metals and their alloys, carbon, acidulated water, and many metallic solutions; but it is only with the first of these that we are concerned, and of the metals practically only two are used—viz., iron and copper; the first being used for overhead telegraph wires and such like purposes only, whilst the latter is always used for the conductors of cables for electric lighting, and other purposes where large currents have to be transmitted. A great variety of substances are used as insulators according to the particular conditions to be fulfilled, the most important being air, wood, slate, porcelain, glass, mica, ebonite, silk, cotton, and other fibrous materials, guttapercha, indiarubber, waxes, oils, and resinous and bituminous compounds.

In one form or another most of these have been tried as insulating materials for electrical conductors, and we, at the present time, have occasion to be thankful to telegraph engineers, in that they by their 40 years' experience of underground work have shown us many methods of insulating conductors which should be avoided, and have given us many hints as to the most likely direction in which we may find success. I do not wish it to be thought that I consider the cable which is best for telegraphic purposes is also best for electric lighting, since the conditions of usage are very different, but rather that, making due allowance for the difference in working condition, much valuable information may be gained from a study of the history of underground telegraph wires.

Before describing the several kinds of cables most frequently used, it will be well to state briefly what are the requisites of a perfect cable. In the first place, the conductor should have as low a resistance as possible for a given weight per unit of length, which means that the copper should be pure, and in this respect we cannot expect to make any great advances, as copper wire can now be obtained commercially which has 98 per cent., and, in some cases, over 100 per cent. of the conductivity of the standard of Matthiesen, which was supposed some few years ago to be the nearest approach to chemically pure copper that could be obtained in the laboratory. The conductor should also be flexible, and this condition is met by forming it of a number of small wires stranded together, instead of a solid wire. The insulating material used must have a fairly high specific resistance; it should be homogeneous and waterproof; it should be mechanically strong and not easily abraided; it should have sufficient cohesion to prevent the conductor sinking through it at high temperature, and should be flexible, so that it will not suffer damage from bending even at low temperatures, and, most important of all, it should be durable, physically and electrically—that is to say, that it should, under all conditions of temperature and other surroundings, retain unimpaired whatever good qualities it possessed when new for as long a time as possible. In addition, the weight, bulk, and cost of the finished cable should be as small as possible consistent with the due fulfilment of all the requirements named above, and the cable should be so constructed as to allow of joints being well and easily made, without reducing appreciably its insulation resistance per unit length. I am afraid that at the present time no cable fulfils all these requirements satisfactorily, as the best cables are, in the opinion of many, too costly, and the cheaper cables fail in several particulars to come up to the required standard.

The insulated cables which are in use at the present time may be divided into two classes: (1) Those which depend for the retaining of their insulation on a water-tight metallic covering outside the dielectric proper; and (2) those in which the dielectric is itself supposed to be waterproof, and which are therefore independent of any such metallic covering. In the first class are included all cables in which fibrous material, such as jute, hemp, or cotton, impregnated with an insulating compound is used, and such cables are made by the Fowler-Waring, Berthoud-Borel, and Callender Companies, by Siemens, and many American and continental manufacturers, and also by others whose names are more generally known in connection with other methods of insulation.

The Fowler-Waring cable is insulated by wrappings of jute or flax impregnated with a hydro-carbon compound, said to be a residuum of petroleum, and then coated with lead by the cold process.

In the Berthoud-Borel cable the conductor is wrapped with spiral layers of cotton, and boiled in a mixture of linseed oil and resin, and then covered with lead by the hot process. This lead-covered cable is then wrapped with compounded tapes, and a second lead covering put on.

In the Callender cable the conductor is wrapped with jute, and boiled in bitumen. It is then wrapped with parchment tape, and covered with lead by the cold process.

The Siemens cable is insulated with jute, impregnated with a compound called by the makers "caoutchicine," and then covered with lead by the cold process.

In all these cables the lead covering is protected by being served with jute or tapes treated with a compound such as asphalte and tar, or similar material, and when they are to be laid in the ground and not in a conduit, the cable is armoured over all by iron wires or tapes. The Siemens cable, which is always laid in this manner, has two reverse laid layers of iron strip put on spirally, outside which again comes a serving of compounded jute. The joints in these cables may be made by soldering the copper in the usual way and then wrapping the joint with prepared tapes. After this a sleeve of lead, previously slipped over the end of one of the lengths of cable, is passed over the joints and fixed to the lead coatings on either side by wiped joints. This sleeve has a hole made in it near the centre, through which insulating compound is passed to fill up all spaces and make the joint solid. In some cases this method is not followed; for instance, the joints in the Siemens cable are made in special joint-boxes made in halves. The outer coverings of the cable are stripped off and the conductors clamped together, not soldered. The two halves of the box are then bolted together so as to enclose the joint and to grip the cable tightly at each end where it enters. The box is then filled with a heavy insulating oil through a hole at the top, which is afterwards stopped by a screw plug. The Callender cable is also sometimes jointed by clamping the conductors together inside a box which is made as water-tight as possible.

From the above description it will be seen that the differences existing between the cables of various makers are in the insulating compound, the exact nature of which is kept a secret, so that discussion of their relative values is not possible; and in the method of putting on the lead covering. The two methods which I have called respectively the hot and cold processes differ in this way. In the hot process the lead in a molten condition passes out through a die, in the centre of which moves the cable to be covered, whilst in the cold process the lead at a temperature far below its melting point is forced through the die by the application of great pressure. This latter process, therefore, has the advantage that the lead covering is put on under considerable pressure, and is therefore less porous and stronger than when put on by the hot process, and also that the covering is much more uniform in thickness since the lead does not allow of the covered conductor sinking into it in the way that it does in the hot process.

In all cables of this class it will be seen that the original value of the insulation resistance is dependent on the complete expulsion of all moisture from the fibrous material, and that the permanency of the insulation can only be maintained by keeping the fibrous material, which is very hygroscopic, from contact with moisture by an air and water-tight casing. Although great improvements have been made in the manufacture of cables of this class, they are still in my opinion open to the following objections :

---

* *Lecture delivered before* the Woodhouse and Rawson employés' *class, March 6, 1891.*

1. Since the insulation depends on the thoroughness with which the moisture is extracted, and this is done by the application of heat which greatly weakens the fibrous material, there is the danger of damaging the fibre or not completely drying it. So far as my experience goes, the success attending this operation is not uniform, so that cables which should be similar do not test the same, and it would therefore appear difficult to decide whether an insulation resistance which was below the average was due to a uniformly lower specific resistance, or to a local fault which ought to be removed.

2. Slight flaws in the lead covering, even if small enough to escape detection as mentioned above when the cable is tested in the factory, will in time lower the insulation resistance considerably.

3. The lead covering is more liable to be damaged by bending and coiling and uncoiling from drums than a flexible insulating covering, and the lead-covered cable is not so easily handled, owing to its being less flexible and more weighty and bulky than cables without metallic covering.

4. Owing to the hygroscopic nature of the fibrous material, there is great risk of the insulation resistance being lowered whenever the leading casing is opened and a joint made.

5. The dielectric not being homogeneous, and the component parts having different rates of expansion, the existence of cracks and fissures is probable, and these cracks offer easy paths for disruptive discharge. Owing to the trouble due to this cause in arc light circuits in America, it was found necessary to double the thickness of the dielectric, making it $\frac{3}{16}$in. instead of $\frac{3}{32}$in.

6. In some soils the lead covering has been found to perish very quickly, due to chemical action, and the destruction of the lead at once causes faults in the cable.

For the second class of cables the insulating material should itself be waterproof, and amongst the substances tried for this purpose are nigrite, kerite, and okonite—all of which are better known in America than over here—bitite, guttapercha, and indiarubber. The first three are all mixtures of rubber with some other substance, the exact composition of which is a secret, and they have all been used with varying success in America for underground work ; but, so far as I know, none of them have yet been tried underground in England.

Bitite, which is the insulating material used by the Callender Company, is said to be bitumen absolutely refined to purity and vulcanised. This class of cable has been used a good deal underground for low-pressure systems, and in one or two instances for high pressure. Personally, I have had no experience of the use of this cable ; but from my general knowledge of bituminous substances, and from particulars given in the press, I should expect to find that the specific insulation resistance was low, and that the conductor was liable to uncentre owing to insufficient cohesion in the insulating material.

Guttapercha, for many purposes the best insulating material that can be got, has earned a justly high reputation for all submarine work ; but for the generality of electric light work it is utterly unsuited, as it does not stand exposure in a dry atmosphere or changes of temperature, becoming brittle at a temperature of between 30deg. and 40deg. F., and softening at about 100deg. F. In fact, the situation as regards guttapercha may be summed up by saying that when of good quality and properly applied, it can hardly be excelled if kept in water at a temperature of from 40deg. to 80deg. F., but that under any other circumstances it takes a much lower place in the list of insulating materials. It is, however, as you no doubt know, used to a very great extent by the Post Office and others for underground telegraph and telephone wires ; and for this work, when the conductor is light, the heating due to the current negligible, and the cable kept at a fairly constant temperature in a moist atmosphere, it gives very satisfactory results.

The insulating material of which I have most experience is indiarubber, and, in my opinion, it is the one from which the best results are obtained. This opinion, if we put on one side the question of price, is, I believe, pretty general, as practically the only objection to the use of good rubber cables is that they are expensive. Indiarubber-insulated cables are made in various ways, and of very different qualities, and it is therefore necessary to distinguish between the several kinds of cable, and to put certain limitations on the general statement made above. At first used for electric light work, a rubber cable consisted of a conductor around which was lapped spirally one or more layers of pure rubber tape, and on this a protective covering of tapes or braiding. This class of cable, although it has done very good work in internal wiring, is not satisfactory for use out of doors, since the covering is neither homogeneous nor waterproof, nor can a sufficient thickness of it be put on, without excessive cost, to stand the mechanical strains of handling. The rubber, in the form of pure tape, is also very susceptible to changes of temperature, and the decomposition which always takes place in unvulcanised rubber is much helped by the application of heat. The statement just made that a pure rubber cable is not waterproof, has been combatted on several occasions, and tests of this cable in water have been quoted. It is quite true that such a cable can be made to test in water by warming it, which makes the adjacent strips of rubber stick together ; but when this is done it is at the expense of the durability of the rubber, as this very tackiness which causes the strips to stick to one another is one of the first results of decomposition.

The next step made in the manufacture of rubber cables was to use a compound rubber instead of pure rubber, and although at first sight this may appear a retrograde step, yet it really was a considerable advance, as, in the first place, it allowed the rubber to be put on the conductor as a continuous coating, and under pressure, which made a much more homogeneous covering than the pure rubber; and, secondly, it allowed a greater thickness of the material to be used without the cable becoming excessively costly, the result of which was that the compound rubber cable was able to withstand handling and rough usage much better than one insulated with the usual amount of pure rubber. As regards durability there was, however, still something to be desired, as even the best compound rubbers were liable to injury by extremes of heat and cold, though in a less degree than the pure rubbr, and were liable to become either too hard or too soft according to the mixture used and to the treatment of the cable, thus losing their flexibility. These physical changes naturally brought with them electrical changes, which were shown by a falling off in the value of the specific insulation resistance.

Cables such as I have been describing were, however, thought to be sufficiently good for all the requirements of the work done until a few years ago ; when, owing to the increase in the amount of electric lighting work, to the use of higher pressures, and to the necessity of laying cables underground, a demand began to arise for a more perfect and more durable type of cable, and to comply with this the vulcanised rubber cable was produced. Looked at in the light of our present knowledge, it seems strange that we should have been content with the older types of cable for so long, since the use of vulcanised rubber was no new thing ; indeed, except for the electric light cables, it would have been difficult to find any manufactured rubber articles where the rubber was not vulcanised ; and even so long ago as 1868 the necessity of treating the rubber in this manner was recognised, when it was used as the insulating material of the core of a submarine telegraph cable. I speak under correction, but I believe that the first instance of cables of this class being used for electric light work was in 1885, when two ships were wired for Messrs. Harland and Wolff with vulcanised rubber cables by the Silvertown Company.

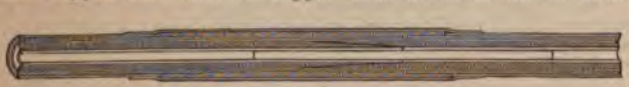
Vulcanisation is brought about by mixing a small quantity of sulphur with the rubber, and submitting the mixture, under pressure, to a temperature of about 300deg. F., when the sulphur combines chemically with the rubber, and thereby neutralises the effects of certain solvents, which, so far I know, cannot be otherwise got rid of.

This class of cable, as now generally manufactured, consists of a stranded conductor of tinned copper wires, around which is first lapped a coating of pure rubber. One or more coats of vulcanising rubber are then put on under pressure, according to the thickness of dielectric required, and the core thus made is tightly lapped with prepared tape. At this stage it is removed to the cures, where the rubber is vulcanised, and then, after being tested in water to see that the rubber covering is mechanically perfect, and of the proper quality, the core is taken to the braiding or taping machines, where the outer covering of compounded cotton, flax, or tapes, which is designed to protect the rubber from injury, is put on. It is this last form of rubber cable which, when first-class rubber is used, well mixed, put on under considerable pressure and carefully vulcanised, gives, in my opinion, better results than any other kind of cable which has yet been produced. Such a cable gives a high and uniform insulation resistance, and the insulating material is waterproof and homogeneous, is sufficiently tough to prevent the conductors from uncentreing, stands a high temperature without softening, is flexible and will stand handling and bending about without injury, and, finally, is very durable. When used for out-of-door work the utmost care should be taken in making the joints, which should always be vulcanised, and when this is done by experienced men the cable with its joints should still test as high per unit length as the separate pieces of cable before jointing.

A good method of making these joints is as follows. The copper joint should be carefully soldered with resin as a flux, and finished smooth and clean. The ends of the rubber which have been exposed during the making of the copper joint should then be pared down to as long a taper as can be made. The bare conductor and the tapered surface of the rubber is first lapped tightly with one or more layers of pure rubber strip, and then with one or more layers of vulcanising rubber, care being taken to lap the rubber so as to exclude air. The joint thus made is tightly bound up with prepared tape, is then covered by a piece of sheeting, making a longitudinal seam, and firmly bound round with selvedge tape. The sheeting and selvedge tape act as a mould to keep the joint in shape during the vulcanising process, and are removed again when this is completed. The bottom half of the cure, which is a cast-iron box with a bolted cover, and having cylindrical openings at each end, is then placed under the cable so that the joint is wholly within it. The cable, where it passes through the end openings, is wrapped with common rubber to protect the original insulation from heat, and to make tight joints at the openings, the cover is bolted on, and molten sulphur is poured into the cure through a hole in the cover. The sulphur is heated by one or more spirit lamps placed under the cure, and the temperature is noted by a thermometer placed in the molten sulphur, and projecting through the hole in the cover. For the rubber used by the Silvertown Company, the temperature should be maintained at about 290deg. to 300deg. F. for half an hour. The molten sulphur is then run out through a tap in the bottom of the cure, the cover removed, and the joint taken out and the wrappings stripped off. A rough test of the success of the process may be made by indenting the rubber when cool with the thumbnail. The rubber should be springy, and yield to the pressure, but no mark should be left. If the mark of the nail remains in the rubber, or the rubber is hard and unyielding, the joint is not a good one. If good, the joint is finished by lapping it with prepared tapes extending a couple of inches or so over the original braiding on each side of the joint. If the hands are kept dry and clean, and care is taken that the surface of the original insulation is clean, and that the new rubber is applied so as to squeeze the air out before it, joints of this kind present no great difficulties. For outdoor work a good-sized jointers' tent should always be provided, so that the jointer and his work may be protected from dust or rain.

I now propose to describe another class of insulated conductors, which, although they cannot be called cables, are yet supplied insulated and protected from the factory. They differ from the cables in that they are supplied in short rigid pieces, which are jointed together as they are laid. The first example of this class, and one which has been extensively used for many years for the low-pressure three-wire systems, is the Edison tube. The conductors are solid copper rods, which are first spun over with dry string, and then placed three together in the proper positions in the centre of a steel tube. This tube is then connected to a pump, and a vacuum created, after which a hot bituminous compound is drawn in to fill up all the space in the tube which is not already occupied by the conductors. These tubes, which are about 20ft. long, are laid in the ground, and are connected together by split junction-boxes, which embrace the steel tube. The copper conductors, which project a little at each end beyond the tube, are connected by short lengths of flexible copper cable, the box is bolted up tight, and filled with hot bituminous compound. Where branches are taken off, T-shaped boxes are used, and the same method of jointing and insulating is followed.

Another example of this class is the Ferranti concentric main which has been laid to convey the high-pressure current from Deptford to the transformer stations from which the distributing network starts. This main consists of an inner tube of copper about 20ft. long, and $\frac{13}{16}$in. external diameter, on which are wound layers of brown paper, steeped in a hot bath of special wax, until the diameter is about $1\frac{7}{8}$in. This insulated tube is then slipped into another copper tube which is drawn down through a draw-plate till it fits tightly over the insulation. The outer tube is then insulated in the same way with prepared paper to a thickness of rather less than $\frac{1}{8}$in., and is slipped into a steel tube provided with a hole in the middle of its length. Hot wax is then forced by a pump through the hole, so as to drive out the air and make a solid mass between the outer copper tube and the steel tube. The tube is then taken to the lathe and the ends are turned to a 6in. taper, one end male, the other female. At one end a solid copper rod, about 18in. long, is driven half its length into the inner tube, and a sleeve of copper is slipped over the outer copper tube and fixed in place by being corrugated, so as to form two or three circumferential indented rings.



Ferranti Joint.

(To be continued.)

BRISTOL.

The following is the report of the Electrical Committee presented to the Town Council last week and adopted last Tuesday:

Your committee remind the Council that on the 10th June last they presented a report to the Council, recommending the Council to take steps for lighting experimentally the area included in Schedule A to the Bristol Electric Lighting Order, 1883—viz., Clare-street, Corn-street, Wine-street, Broad-street, and High-street—and that the Council resolved that it was desirable that the Corporation should keep the control of the supply of electricity for lighting and other purposes in its own hands, and that the report be referred back to your committee that they might advise the Council as to the desirability of adopting a scheme for lighting a larger area than that suggested by the report and for supplying private consumers with electricity. Your committee have given the subject so referred to them their earnest consideration, and now advise the Council that the area to be at first lighted should be extended, so as to include, in addition to the area in Schedule A, the following streets and places—viz., Victoria-street, Bristol Bridge, Baldwin-street, St. Augustin's-parade, College Green, Park-street, Queen's-road to the Victoria Rooms, Union-street, Dolphin-street, Peter-street, Castle-street, Old Market-street, Small-street, and Bridge-street, and they have obtained from Mr. W. H. Preece a descriptive report of the best method of lighting the area and of supplying electricity for private lighting in the neighbourhood, and an estimate of the cost. The report and estimate, together with a plan of the area to be lighted, are submitted herewith. The installation recommended by Mr. Preece is intended only as a commencement, and is so designed as to be capable of future extension to every portion of the city to which it may be considered desirable to extend electric lighting. Your committee recommend that the alternate-current transformer system, which is available for motive power as as well as for lighting, be adopted for electric lighting by the Council: That your committee be authorised to carry out an installation, upon that system, capable of supplying electricity to 100 arc lamps for street lighting, and 10,000 glow lamps for private *lighting, in the area shown in* the plan, at a cost estimated not to *exceed £66,000; to obtain tenders* for the necessary machinery and works; and to employ such professional and other assistance as they may require. Your committee consider that the most suitable site for the erection of the central station is a block of properties belonging to the Corporation, and situate in Temple-backs, near St. Philip's Bridge, and your committee, with the concurrence of the Finance Committee, have arranged for vacant possession on the 25th inst. of the central portion of the block, on payment of £250 to the occupiers. Your committee recommend that the whole block be appropriated for the erection of a central station (the central portion, for vacant possession of which your committee have so arranged, being used for the erection of the works necessary to carry out the proposed installation, and the remainder being reserved for future extensions), on terms to be arranged between your committee and the Finance Committee; and that your committee be authorised to remove so much as may be necessary of the buildings, of which possession will be obtained on the 25th inst., and to agree with the lessees and occupiers of the other buildings for possession thereof when necessary. The sum of £66,000 required to carry out the installation may be raised either by borrowing the same upon mortgage of the general district rate and fund, or by the issue of stock, under the provisions of section 52 of the Public Health Acts Amendment Act, 1890. Your committee propose to consider which method will be the most desirable one, and to report thereon at a future meeting of the Council. Your committee recommend that if any surplus should remain out of the sum of £66,000, after carrying out the proposed installation, it should be used in extending the lighting to the top of Stoke's-croft, through Broadmead and North-street.

Mr. Preece's report is as follows:
